Electrical

SUPPLEMENT TO "THE ELECTRICAL ENGINEER," JUNE 24, 1892.

THE

ELECTRICAL ENGINEER.

A WEEKLY JOURNAL OF ELECTRICAL ENGINEERING,

WITH WHICH IS INCORPORATED

"ELECTRIC LIGHT."

VOLUME IX. (NEW SERIES.)

FROM JANUARY 1, 1892, TO JUNE 24, 1892.

LONDON:
Printed and Published for the Proprietor by BIGGS & Co., at "THE ELECTRICAL ENGINEER" Offices, 139-140, Salisbury-court, Fleet-street, E.C.

1892.

INDEX TO VOL. IX. (New Series.)

NOTE.—General Articles, Correspondence, and Companies' Meetings are indicated by heavier type (thus, 290) than the Notes, references to which are shown by light type (thus, 290).

THE

ELECTRICAL ENGINEER.

No. 1, Vol. IX. LONDON, JANUARY 1, 1892. PRICE 3D.

NOTES.

Crystal Palace Exhibition.—The opening of the Electrical Exhibition, which was fixed for January 1, has been put off until January 9.

Marennes.—The town of Marennes, France, has made the jump from oil to electricity without passing through the intermediate stage of gas.

Paris Lighting.—The Continental Edison Company's gross receipts for electric lighting during the month of November, 1891, amounted to 245,613f.

Unicycle Electric Road.—It is said that Chicago is to have an electric unicycle railroad, to run from Lake-street to Jackson Park, on which the cars are to run at the rate of 40 miles an hour.

Aberdeen Tramways.—A movement is on foot at Aberdeen to extend the tramway to the Links, and the sea beach. The electric traction engineers should put in a word as to their systems.

Factory in Paris.—A factory for manufacture of indiarubber is to be sold by tender in Paris, January 3rd. Apply M. Navarre, 61, rue des Petits-Champs, or M. Fauchey, 3, rue de Louvre.

Budapest.—M. Victor Popp has withdrawn his tender for the supply of compressed air to Budapest on the ground that as he has no electric light concession, compressed air alone would not pay.

Verviers.—Tenders will be received till 9th February for an electric installation for the theatre at Verviers. The specification will be sent for 2f. and plans for 40f. on application to M. Ch. Thirion, rue Franchée, Verviers.

Brighton Electric Railway.—At the last meeting of the Brighton Town Council the question of entering into an agreement for the use of a portion of the foreshore for the electric railway was brought up, but was adjourned.

Taunton.—The matter of purchase of the Taunton electric station by the Town Council is still under the consideration of the Lighting Committee, and nothing definite will be settled till after the Council meeting in January.

A Large Ammeter.—The Weston Electrical Instrument Company, of Newark, New Jersey, are constructing which is supposed to be the largest ammeter yet made, to indicate 5,000 amperes, for the Willson Aluminium Company.

Philippopolis.—An exhibition will be held at Philippopolis in September, 1892, and is announced as an excellent opportunity of introducing new machinery into the Balkan territory. M. A. Gobiet, Prague-Karolienthal, Austria, will furnish particulars.

Personal.—Mr. M'Clean, who used to have charge at the Grosvenor Gallery and afterwards went to Deptford, has now sole charge at the Oxford central station. He is also superintending the exhibit of Elwell-Parker dynamos at the Crystal Palace Exhibition.

State Control of Belgian Telephones.—The Belgian Government, states a Reuter's telegram of Dec. 30, has informed the Belgian telephone companies of its intention to resume from January 1, 1893, the working of all the telephone lines in Belgium.

Consulting Engineers.—Mr. Frank J. Sprague, Dr. Louis Duncan, and Dr. Cary T. Hutchinson have united to form a limited company, having offices at 15, Wall-street, New York, as consulting electrical engineers, to advise and report upon electrical engineering enterprises.

Liverpool Overhead Railway.—We understand that, in deference to an agitation amongst the inhabitants of Princes Park, the promoters of the Liverpool Overhead Railway have decided to abandon that part of the project which would bring the railway within the limits of the park.

Madras Tramways.—At a recent meeting of the Madras Municipal Commission it was decided that a tramway concession be granted to Hutchinson and Co., of Craven-street, Strand, W.C., on the conditions submitted by them, subject to a security of Rs. 10,000 being deposited in the bank.

South African Cables.—The Eastern and South African Telegraph Company, Limited, notifies the restoration of its Aden-Zanzibar cable, thus re-establishing telegraphic communication with South Africa by the east coast. Both the east and west coast routes are now in working order.

Manchester.—The invitations for sending in tenders for the Manchester central station are at last issued, and can be seen in our advertisement columns. The conditions of tender can be obtained from Mr. C. Nickson, Town Hall, Manchester, by application in writing, enclosing two guineas, and the tenders must be received by January 20.

Electric Locomotive.—The Thomson-Houston Company, not content with the large locomotive we mentioned the other week, are building another and larger, which is to draw a train at 40 miles an hour. The pull is to be 6,000lb., and the locomotive will weigh 16 tons, and develop 250 h.p. Electric railway traction is stepping along.

Electricity in Mining.—Prof. W. Robinson delivered last week, at Nottingham University College, one of a series of lectures arranged by the National Association of Colliery Managers. The subject was "Electricity in Mining." The lecturer dealt technically with the production of currents and the application to mines in hauling and lighting.

Electric Bicycle Trainer.—The partner of a well-known Coventry bicycle rider, who is an electrician, has invented an electric pacemaker, but cannot induce his

friend to try it. It is an electric arrangement which will stick a pin into the rider when his pace falls below a 2·40 pace, though a switch would be required while getting up speed or stopping.

Pontypool.—At the last meeting of the Pontypool Local Board an extensively-signed petition, asking the Board to adopt some system of lighting other than that of gas, respecting which serious complaints were made, was presented. After a discussion, Mr. G. H. David gave notice that he would propose a resolution dealing with the subject at the next meeting.

Popp System at Paris.—The third Popp generating station at the Quai de la Gare, Paris, was opened on the 3rd ult. This station for electric lighting makes the third the system, which now has plant capable of giving 20,000 h.p. The three services of pneumatic clocks, distribution of power, and distribution of electric light consume at the present moment 6,000 h.p.

Portelectric System.—This system, which dispenses with motors on its cars by shooting a suitably arranged trolley through a series of solenoids, has been thoroughly tested for over a year in one of the suburbs of Boston. The system is now to be tried on a much larger scale, and will be tested in actual commercial service. A company with 5,000,000dols. has been formed.

Acton Hill Works.—Mr. Ronald A. Scott, of Acton Hill Electrical Works, issues a fifth edition of his catalogue, which illustrates the "Actwell" dynamos and motors, and more particularly search-light projectors of the Admiralty pattern, in which department Mr. Scott has had much success. Details of mirrors and of Admiralty pattern switchboards of solid type are also given.

Christmas Presents.—We beg to acknowledge, with thanks, the receipt of blotting pads and almanacks for the year 1892 from Messrs. Crompton and Co., Limited, Mansion House-buildings, and from the Electrical Power Storage Company, of 4, Great Winchester-street. We have also received a calendar from Messrs. T. Fletcher and Co., the well-known gas-heating appliance manufacturers, of Warrington.

New Firm.—We are informed by Sir Frederick Bramwell that from January 1, 1892, Mr. H. Graham Harris, who has for so many years been his principal assistant, will become his partner, and that the business heretofore practised at 5, Great George-street, Westminster, will be continued under the style of "Bramwell and Harris," to whom it is requested all letters on matters of business should be addressed.

Bradford Tramways.—The Local Government Board have sanctioned the proposal that the North Bierley Local Board borrow £10,000 for the purpose of constructing a tramway from Bradford to Wyke. A draft lease is to be prepared for the letting of the Bradford and Sheffield Tramway Company. It is to be hoped that the example of Leeds, with regard to new tramways, will have a fair chance of imitation on this line.

Bacup.—A sub-committee of the Bacup Town Council has been appointed to obtain estimates for the laying on of the electric light, of the probable number of persons who would become consumers in the event of such light being provided, and the following constitute that sub-committee: The Mayor (Mr. Councillor Salmon), Aldermen Greenwood, Hardman, and Shepherd; Councillors Barrowclough, Priestley, Smith, and Stockdale.

Glasgow.—At the meeting of Glasgow Police Commissioners last week, Councillor Gray reported the proposal to light the principal streets by electricity would be practically *taken up*. The streets proposed to be lighted were Argyle-street, Jamaica-street, Buchanan-street, Sauciehall-street, and St. George's-square. If they should carry out this scheme it would make the city more attractive after darkness set in, and also be a preventative of crime.

Bosphorus.—M. Charles Georgi, who already has the concession for lighting by gas of Cadikeng and other Asiatic villages of the Bosphorus, has now petitioned for a 60 years' concession for the lighting by gas or electricity of Pera and Bechiletach. M. Georgi stipulates to construct a station, at the expense of £8,000, capable of giving 42,000 cubic metres of gas for 24 hours, or equivalent, and to pay a royalty of 15 per cent. to the Government.

Electricity in Chemical Industry.—A large international company is now, we are told, in process of formation in England to put to practical proof the inventions in electrolysis made by Mr. C. Kellner, factory director, of Vienna. This discovery appears to be a new method of production of chlorate of chalk and soda, which has proved extremely cheap compared with present methods. The names of well-known heads of large German industries are stated to be on the books.

Utilisation of Water Power.—The United States Consul-General in Frankfort, in a recent report, describes the Lauffen transmission plant as the most momentous experiment in technical electricity ever made since electricity has been rendered serviceable to mankind. After a lengthened description of the details, Mr. Mason concludes: "The way is now open for Americans to harness the wasted energy of Niagara and a thousand smaller cascades and rapids in every part of our great country to the varied purposes of daily life."

Harwich.—The bringing forward of the memorial to the Board of Trade for a provisional order at Harwich was the cause of a considerable scene, several of the councillors denouncing the expenditure of £50 for this purpose as dead loss, one member remarking that he had had some conversation with a gas director, and that if the memorial were dropped the gas company would meet them fairly. It was, however, resolved to seal the memorial, but, nevertheless, negotiations are to be opened up again with the gas company.

Cork Tramways.—A scheme has taken definite shape in Cork, we learn, for the introduction of a new and improved tramway system. The project is the outcome of local enterprise. The centre of the city is first to be served, and afterwards the line will be extended to the suburbs. The present would seem to be a favourable time, therefore, for submitting fullest information to the promoters of the advantages of electric traction, which are more apparent for a new scheme even than for adaptation of an old line.

Fairy Lamps.—Some rather smart work in stage lighting was done last week by the Mining and General Electric Lamp Company. On Wednesday afternoon, at three o'clock, the order was received by telegram from Mr. Oscar Barrett for a set of jewel lamps for the Crystal Palace Boxing Day pantomime of "Forty Thieves." The batteries were ready, but all the fittings had to be made and fixed, and by the next afternoon the ballet were fitted up with 32 brilliant lamps, which shone and sparkled above the limelight like stars.

Telautograph.—We read that a large factory is being erected in America for the manufacture and equipment of the writing telegraph, or telautograph, of Prof. Elisha Gray. This seems to indicate considerable proposed activity in the near future. It will be remembered that the writing telegraph was shown in operation in England, and amongst other places at Mr. J. W. Swan's house, but

nothing further has been heard of it, principally from the refusal, we believe, of the Postmaster-General to license this invention for actual use in England.

Liverpool.—At the meeting of the Liverpool Watch Committee on Saturday a resolution was adopted that the town clerk inform the Board of Trade that the Council object to the provisional order applied for by the Liverpool Electric Supply Company, Limited, and also a resolution that the consideration of the memorial signed by consumers of electricity in Liverpool, requesting the Corporation to give their consent to the application of the Liverpool Electric Supply Company, Limited, for a provisional order, be postponed until the second meeting in January.

Primary Battery Lighting.—The ever-fascinating subject of lighting a small private house with a primary battery is treated in *Cosmos* by M. de Contades in a somewhat novel way, illustrated in detail. The writer describes, apparently from an existing installation, an arrangement for charging secondary batteries from two large sulphate of copper cells with an automatic switch for cutting the secondaries into series. These light 10 lamps, each of ·5 amperes, at 50 volts, for seven hours a day. The capacity of the charging cell, working for the other 17 hours, is 1,020 ampere-hours.

Motor Patents.—The publication has already been made of the contents of an Italian patent granted some time before the construction of the first industrial dynamo, for the utilisation of current from one machine to set in motion a second. The *Bulletin International* announces that another and earlier patent has been discovered, granted June 30, 1866, to Signor Felice Marco, of Florence, for the utilisation of waterfalls for driving electric machines whose current carried by metallic wires should put in motion other receiving electric machines, installed where the power is required.

Electric Carriages.—An electric carriage has been fitted up by Mr. William Morrison, of Des Moines, Indiana, and is illustrated in the *Electrical World* for Dec. 19. It is a handsome waggonette, with light wheels and cushioned seats, with a rotary wheel for steering. The motive power is obtained from 24 accumulator cells placed under the seats, and the motor is connected to the rear axle by reducing cog gearing. The winding is arranged so that reversal of the current reverses the movement of the car. This carriage has been in practical operation in Des Moines for some time, and will soon be shown in Chicago.

Heckmondwike.—A meeting of the Heckmondwike Electric Lighting Committee was held last week. Mr. Hutchinson, C.E., attended, and produced and explained the plan and scheme prepared by him for the proposed lighting of the district by electricity, when it was resolved that the scheme set out on the plan be approved. Mr. Hutchinson also produced and explained the draft specification for the proposed electric lighting from the proposed station in Oldfield-lane, and a resolution was approved authorising the completion of the specification, and that a copy of the same be supplied to each member of the committee. The minutes were approved.

Margam Abbey.—The residence of Miss Talbot in Wales, Margam Abbey, has been fitted up with combined steam and turbine plant. The turbine is of 25 h.p., and the steam engine, of the same power, drives on the same countershafting. Accumulators for 100 lamps are placed in the Abbey, and there are 400 lamps of 16 c.p. in all. The pipes for the conveyance of water power are 18in. diameter, and weigh in all 90 tons. The cables are laid from the engine-house in cast-iron pipes, which also carry six telephone wires for a private exchange. The whole of the work has been carried out by Messrs. Drake and Gorham, Mr. Campbell Swinton being called in as consulting engineer.

Typewriter and Telegraph.—In our note last week upon the use of typewriters in telegraph offices of the United States, it was mentioned that the only objection seems to be the extra noise, the Remington and Caligraph being most used. We are informed by the Typewriter Company that the sale of the Bar Lock typewriter is also very large amongst telegraph companies, for the reason, it is claimed, that the noise in working this machine is less than others. The economy and efficiency accomplished by the typewriters is very suggestive, and the large field here opened will evidently cause keen competition amongst the various makers, as it cannot be very long before their use is introduced almost universally.

Croydon Electric Cars.—Another trial trip of the Jarman electric cars, which are to be run in Croydon, took place on the lines of the Croydon Tramway Company last week. The first journey was made to Thornton Heath quite successfully and smoothly. On returning a slight mishap occurred by running the cars too close together, and a jar occurred which broke a window. The fully-loaded cars were easily stopped, started, or backed. After the trial a luncheon was taken, at which Mr. Archer, of the Electric Tramcar Syndicate, and Mr. Carruthers Wain spoke as to the future of electric tramcars. Mr. Lintilhac, chairman of the syndicate, presided, and there were present several of the directors of the Croydon Tramway Company and members of the Town Council.

Electrical Apparatus.—Messrs. Dorman and Smith, in the new issue of their catalogue which is before us, insist rightly upon their position as first-hand manufacturers of electrical apparatus. They do not undertake bell, telephone, or telegraph work, or installation contracts, but are the more busily engaged in turning out all kinds of switches, roses, fuses, switchboards, brackets, and pendants which are in such large and continuous demand. This demand, indeed, is increasing so fast that Messrs. Dorman and Smith have been compelled to take new works in Salford, and these will soon be in full swing. Besides the very large selection of ordinary fittings for house and ship lighting, special attention is given in the catalogue to Sunbeam lamp fittings, a department that is evidently growing.

Electric Construction Corporation. — An "Accountant" writing to the *Financial News* says that he was so disappointed at the result of the year's work of the above company that he sold out his holding. His reason for so doing was that the profit of £160,036 was gained at an expense of £162,434 (expenses and cost of production, £129,890; depreciation of machinery, etc., £3,099; head office expenses, etc., £11,423; auditors' fees, £105; interest on debentures, etc., £3,949; other expenses, advertising, etc., £13,968), or a loss of £2,400 on the year's legitimate business, and had it not been for the sale of part of the patents for £64,000 no dividend could have been paid. This is exceptional, and he thinks it does not reflect much credit that in spite of the large turn-over the expenses were in excess.

Ipswich.—At the last meeting of the Ipswich Lighting Committee a letter was read from the Board of Trade inviting observations upon a letter from Messrs. Waterhouse, Winterbotham, and Harrison, 1, New-court, Carey-street, in which that firm wrote with reference to the Ipswich electric lighting order: "We are instructed by our clients, Messrs. Laurence, Scott, and Co., to request that this order may be revoked. Our clients feel that it is not

possible to work two electric lighting undertakings with profit in Ipswich, and they have therefore arranged with the Ipswich Electricity Company that the order granted to that company only shall be acted upon. Under these circumstances we trust that the Board of Trade will consent to the revocation of our clients' order." It was resolved to offer no opposition to the revocation of the order.

London Meat Markets.—Mr. William Malthouse, writing from the Central Meat Market to the *City Press*, says: "The tenants of the Central Meat, Poultry, Provision, and Fish Markets have petitioned the Grand Markets Committee of the Corporation to give them the electric light. I should like the members of that committee to have been here these last six mornings, when nearly 10,000 tons of meat were delivered into the market, and carted away to all parts of the metropolis and the country. The superintendent (Mr. Stephens) and his staff must have had a gigantic task, and have done it well, under circumstances of fearful difficulty and danger. What a mighty boon the electric light would have been to us all. A few market tenants on the committee would, by their practical experience, have rendered great service in this matter."

Canada.—The Dominion of Canada is among England's largest colonial possessions, and yet is very little worked by British enterprise. It has an area of 3,382,000 square miles, which represents one-sixteenth of the entire land surface of the globe, considerably more than the whole of the United States. Yet it only has a population of five millions, or about that of London. In electrical fields it might be better supplied, and its resources developed, as by reason of its long winter it offers considerable opening in this department. The Toronto Construction and Electrical Supply Company have recently canvassed the whole country for electrical goods, and have representatives 4,000 miles apart, in British Columbia, and in Halifax, Nova Scotia. The latter town has a climate much like that of England, and is worthy of more support from the old country.

Electric Stores, Limited.—A private company was formed in the early part of the year which is past under the name of Electric Stores, Limited, having offices at 51, Cannon-street, and lately a showroom has been opened at 10, Bow-lane, E.C. The company, as its name implies, is formed for the supply of stores and electric apparatus of all kinds. The chairman is Mr. Albert Hoster, who is the director of the large incandescent lamp factory at St. Nicolas, near Dieppe. These works cover about an acre of ground, and are carried out upon English principles, having cost about £25,000 to erect, English electricians having been taken out for training the workpeople. The Electric Stores have as manager Mr. Tumber, late of one of the telephone companies. The Company are putting up a large exhibit in the Crystal Palace Exhibition.

Cost of Electric Lighting.—In a letter to the *Financial News*, with reference to a recent article on the cost of electric lighting, Messrs. Crompton and Co. say that as engineers and contractors they are prepared to prove under penalty that what is termed the "sheer cost" of producing the electric light is not greater than that of gas, and that this cost has already been reduced to the low figure of 2d. per Board of Trade unit supplied. The discrepancy between this and the figure charged is due simply to the cost of the large plant and the general expenses, which until the load is high bear a large proportion to the sheer cost. Mr. Harston, writing next day, states that whatever the actual cost may be, from the House-to-House Company (with whom, however, he wrongly associates Mr. Crompton) *the cost is three times* that of gas, and he adds that three 8-c.p. lamps are not equal in light to three 5ft. Peeble's burners.

Reading.—The question of the public lighting of Reading is being pressed for immediate settlement, and it is to be hoped that an arrangement can be come to for lighting the principal streets and the muncipal and other offices by electricity. The Lighting Committee have presented a report in which they detailed the terms on which the Laing, Wharton, and Down Construction Syndicate undertook to light the central business area under an alternative arrangement of a five or seven years' contract. The expense would be half as much again as the present charge for gas, and the light would be about 15 times as much as that now in use, besides which the electric light would be kept alight the whole night, whereas the gas is shut off or cut down part of the night. An amended estimate, by which the arc lights can be shut off at eleven o'clock, substituting incandescent lamps after this hour, is also prepared, and this arrangement being less expensive would probably be favoured by the Council.

Leeds Electric Tramway.—The combination of Christmas and fog has brought about conditions in Leeds which have tested, as well as anything could possibly do, the capacity of the Roundhay Park electric railway. The dense fog was the worst ever known at Leeds, but in spite of the weather the cars have been crowded at every journey, running 500 car miles a day. Through all this no trouble whatever has been found in the electrical part of the work. The engine-room has been running as smoothly as clockwork, the only accident being a little collision between two of the company's own cars, due partly to the dense fog, but also to carelessness of the driver, who was dismissed. The holiday traffic has been very heavy, and it is indeed marvellous, considering both the conditions we recorded, of quick work needed for first installation and the subsequent bad weather, that the Thomson-Houston Company have at once made such a success of their line. The line will very shortly be run down into the centre of the town.

Helsten (Cornwall).—On the 14th of October, the Helston Town Council, at a special meeting, passed a resolution that application be made forthwith to the Board of Trade for a provisional order. Since that time the municipal elections have been held, and were fought to some extent upon the lighting question. At the last meeting of the Town Council a resolution was brought forward to rescind the above. Mr. Taylor moved an amendment that all action should be left pending negotiations with the gas company. He said that the reason the burgesses were opposed to the electric light was that all sorts of stories had been told them at election time, that the rates would be raised 4s. or 5s. in the pound, and so forth. He objected to throwing themselves into the hands of the gas company, with gas at 5s. 10d. per 1,000ft. The Mayor thought it would be wrong to introduce the electric light on the terms which had been mentioned by Mr. Veale, and said the gas company would deal fairly with the Corporation. After further discussion the resolution was rescinded, the Mayor giving a casting vote.

Dundee.—A meeting of the Property Committee of the Town Council was held last week, when it was explained obstacles had arisen in the way of the Gas Commission acquiring the Ward-road site as a station for the electric lighting works, and it was agreed, at the request of ex-Provost Brownlee, to take about 60 poles of the ground belonging to the town at the Old Cattle Market at £2 per pole, with a view to the Gas Commissioners securing that as a site for their electric light station. The ground at present is partly leased to Messrs. Livermore Brothers, and partly occupied as a yard by the Water Commissioners at

a rent of about £60 per annum. The Electric Lighting Committee has thus practically adopted the alternative proposal which was originally defeated at the meeting. About six weeks, however, must elapse before the ground can be obtained. As it is beyond the compulsory area, way leave for the cables is necessary, and on Monday Councillor R. D. B. Ritchie brought the matter up at a meeting of the Works Committee of the Police Commission, at which it was agreed to grant the way-leave.

Private Exhibition in Ireland.—The Electrical Engineering Company of Ireland entertained their friends the other day with an exhibition of electric light illumination for indoor decoration, comprising early tea, a combination much enjoyed by the fair sex. The novel arrangements on the tables and throughout the rooms were particularly admired. On the tea-table some of the incandescent lamps of various colours were entirely enclosed within a light Persian drapery—a striking method of decoration which is only possible where the electric light is available. The general illumination of the room was effected by means of a central electrolier, artistically decorated with festoons of prepared seaweed, and from the ceiling depended a number of pearl shells, similarly decorated, and through which a charming iridescent light was diffused. The visitors were shown over the establishment, the working of the gas engine, dynamo, and storage batteries being explained. A device constructed of small incandescent lamps, arranged in the form of the initial letters of the company, "E.E.C.," brilliantly illuminated the window and footpath.

Covent Garden Carnival Ball.—The Covent Garden Theatre was a brilliant scene on Wednesday night, when the first of Sir Augustus Harris's carnival fancy dress balls was held. The floor had been raised to the level of the stage, and the immense horseshoe shape was covered with a prepared canvas for dancing. Above the stage, raised on fluted white and gold columns, was the orchestra, comprising some hundreds of performers. The music, as may be imagined, was the finest that dancers could wish. The house, in gold and crimson, was brilliantly lighted up with hundreds of incandescent lamps turned on for the first time on this occasion. The sides and balconies were a mass of lovely cut flowers, and the numerous stalls were all decorated with magnificent bouquets. At half-past eleven dancing commenced, and soon after twelve the whole floor was a maze of moving figures, most of them in fancy costumes, making a most imposing and gay assemblage. Dancing was kept up till five or six. We should mention that the electric light was fitted up by Mr. Forrester, their own gas engineer, and the current was supplied by the Metropolitan Electric Light Company.

Bernardos Welding Process.—A large party inspected on December 21st the installation of the improved Bernardos electric welding system at the works of Messrs. Lloyd and Lloyd, Halesowen, proprietors of the patents in this country. The Bernardos process, as distinct from the Thomson process, uses an arc for the purpose of fusing the metal. In actual use a continuous-current dynamo is connected to a set of accumulators, and at the moment of welding both are used in parallel. The work, such as an iron tube, is laid on a metal table which forms one pole. The other cable is connected to a large carbon rod much like soldering-iron, and the arc is struck between the carbon and the tube, the arc being sometimes as much as 6in. long, and of one or two square inches in sectional area. The current used is varied from 10 amperes to 400 amperes. Demonstrations were made of the welding of tubes, wheels, and rods, and of the cutting up of thick iron plates to shape with great success. The later improvements consist in an arrangement for rotating and vibrating the arc to distribute the heat, and an electric power hammer is used to finish the welds. Amongst those present were Sir Redvers Buller, Sir Frederick Abel, Sir Douglas Galton, Prof. Forbes, Mr. McFarlane Gray (Board of Trade), Mr. J. Spencer (Newcastle-on-Tyne), Mr. W. H. White (Admiralty), and Mr. J. Howard, M.P., representing the firm. The firm have granted licenses for the use of the system to Messrs. John Spencer and Sons, Limited, of the Newburn Steel Works, Newcastle-on-Tyne, and other firms.

Electric Organs.—The subject of electricity as applied to large organs is occupying a great deal of the attention of professional organists and organ builders, and Mr. R. Hope Jones, of Birkenhead, who has made a speciality of the question, in his address on "Electrical Control of Organs," on December 19th, before the Yorkshire division of the National Society of Professional Musicians at Leeds, gave some interesting details of his work. Mr. Jones first glanced at the forms of organ action—mechanical, pneumatic, tubular-pneumatic, and electro-pneumatic. With the latter all tubes were removed for a small electric cable, and the pneumatic part was much simplified. He expressed the conviction that the electric would shortly be the only form that organ builders would use in constructing large or moderate-sized organs. Sufficient current to work a large four-manual could be supplied by a single dry cell, and a few shillings would supply a new cell. The organist then became simply a toucher of wires. Noticing the advantages which made the electric action irresistible from an organist's point of view, Mr. Jones mentioned light and adjustable touch. The rapidity in response and repetition secured was really wonderful, mechanical tests proving this action to be capable of no less than 1,300 clear repetitions per minute. In connection with the details of his own system there was one feature which he published for the first time that afternoon. He referred to what he termed the "second touch," the object of which was to give, as far as possible, to the organ keys the individual expressiveness of the pianoforte. He applied this second touch to each of the manuals and to the pedals. Among the other advantages which electricity offered he enumerated the following: Movable console; stop keys, saving the organist labour and giving better control of the registers; the stop-switch, by which combination of stops might be arranged beforehand and brought into use at the moment required; unlimited combination touches; keys or studs for the automatic control of the pedal registers; suitable accompaniment; unlimited couplers; increased control of the swell shutters; and the transposition switch. The only single disadvantage that could be named was the need for a supply of electric current, but as they could obtain all that they required from a single cell, they need not fear inconvenience from this. Mr. Jones said that he had always felt that but for the enterprise of Messrs. Abbott and Smith his attempts in regard to electrical organ control would never have led to any greater results than the experimental organ in St. John's Church, Birkenhead. A year ago that instrument was of little interest to anyone but himself and the choristers, who helped him to build it. The organ had, however, during the year been visited by nearly 1,500 musical gentlemen, and 23 London and provincial organ builders were now duly licensed and engaged in the introduction of the system. The meeting passed a hearty vote of thanks to Mr. Jones for his address. The company then visited the factory of Messrs. Abbott and Smith, and inspected the model of an electric organ which the firm is erecting.

OUR PORTRAITS.

Crookes, William, F.R.S., P.P.C.S., President of the Institution of Electrical Engineers, 1891. Born in London in 1832; entered Royal College of Chemistry in 1848 as a pupil of Dr. Hofmann, and gained the Ashburton Scholarship in 1849. In 1850 he became junior, then senior, assistant to Dr. Hofmann, which position he retained till 1854, when he obtained the appointment of superintendent of the Meteorological Department of the Radcliffe College, Oxford. Elected a Fellow of the Royal Society in 1863. Mr. Crookes founded the *Chemical News* in 1859, of which paper he is still the proprietor and editor. Mr. Crookes has been president of the Chemical Society and of the Chemical Section of the British Association. He is an indefatigable investigator and writer, and his researches upon high vacua stamp him as one of the foremost of the scientific men of the nineteenth century.

Ayrton, Prof. W. E., F.R.S., President of the Institution, was educated at University College School, where he gained numerous prizes, and entering subsequently into the college, gained the Andrews Exhibition in 1865 and the Andrews Scholarship in 1866. Subsequently Mr. Ayrton entered the Indian Telegraph Department, first studying under Sir W. Thomson at Glasgow. In India Mr. Ayrton did good and lasting work with the late Mr. Schwendler. From 1873 to 1879, Prof. Ayrton was Professor of Natural Philosophy and Telegraphs in Japan. Since his return to England his name, often in conjunction with that of his colleague, Prof. Perry, has been constantly before scientific circles. The number of papers he has individually, or in conjunction with others, contributed to the learned societies is very great. His career at the Finsbury College, and subsequently at the Central Institution, is well known to most of our readers, who, if they require an example of extraordinary energy, coupled with great abilities, cannot do better than emulate the President of the Institution for 1892.

Webber, Major-General Charles Edmund, C.B., R.E. (retired), Past-President of the Institution, and one of the two founders, his colleague founder being the late Sir Francis Bolton. Born in Dublin, 6th Sept., 1838. Educated at the Royal Military Academy, Woolwich, and obtained his first commission in the Royal Engineers in April, 1855. Major-General Webber's war services comprise the Indian Mutiny, 1857 to 1859, and he was attached to the headquarters of the Prussian army in the Austro-Prussian War of 1866. He was employed in Asia Minor in collecting transport for the Abyssinian Expedition. In 1879 and 1880 he was in Zululand, Natal, and latterly in the Transvaal, with the Egyptian Expedition of 1882, employed as staff-officer for telegraphs; present at the battle of Tel-el-Kebir, A.-A. and Q.-M.-General and Director of Army Telegraphs with the Nile Expedition of 1884-5, until invalided in May, 1885, retired from the service with the honorary rank of major-general in 1885. Of late years General Webber has been closely connected with electrical engineering, and especially with the Brush Company and the Chelsea central station; also with the system of main-laying known as the Callender-Webber system.

Preece, W. H., F.R.S., Past-President of the Institution. Born 1834, near Carnarvon. Educated at King's College, London. Entered Mr. Edwin Clark's (M.I.C.E.) office in 1852. Appointed to the E. and I. T. Co. 1853. Superintendent of the southern district of E. and I. T. Co. 1856, and of L. and S. W. Railway Co. in 1860; also engineer Channel Islands Telegraph Co. 1858; transferred to P.O. as divisional engineer 1870; appointed electrician 1877. If we say little more of Mr. Preece's career, it is not from lack of material but from lack of space. In fact, it seems almost a work of supererogation to attempt to make more prominent one of the most prominent figures of the age in electrical and telegraphic circles. Like other eminent men, the list of his contributions to the scientific literature of to-day is very extensive, and we only regret that he has not found time to add further to it by a contribution to our columns. If the idiosyncrasies of Mr. Preece were sought out, they would probably be found to consist of a thorough groundwork of strong common-sense, and a special ability to popularise his subject. More power to his elbow.

Webb, F. H., secretary to the Institution, was educated at the Ecole Normale, at Brussels, and University College, London. He afterwards went to Germany to study for the profession of an engineer. Then for six years he held the post of resident-secretary and librarian to the Royal Institute of British Architects. He was in the engineer's office of the first telegraph company, and for 10 years was private secretary to the late J. L. Ricardo, M.P., founder of that company. Mr. Webb subsequently held secretaryships to several companies, and amongst others that of assistant secretary to the London and Brighton Railway. Upon the resignation of Mr. Langdon in 1878, he was appointed editor of the Institution of Electrical Engineers' *Journal*, and secretary to the Institution, which latter position he has held up to the present time. The great interest he takes in all that concerns the Institution is well known to members. It is by no means an easy task to steer a great institution through the quicksands of public criticism, and we venture to think that Mr. Webb has by his constant and unwearied courtesy done much to raise the Institution to its present pitch of prosperity.

Salomons, Sir David L., Bart., one of the Vice-Presidents of the Institution, was born in 1851, and educated by private tuition, and at Caius College, Cambridge, where he graduated in the Natural Science Tripos. Sir D. Salomons has done excellent work of recent years in assisting forward electrical engineering in several departments. A great debt of gratitude is due to him by the profession by his thoroughly exhaustive test, under private and unbiased auspices, of electric lighting at his residence near Tonbridge, where also he was one of the first, if not the first user on a practical scale of secondary batteries, and of motors applied to actuate his various lathes and similar machines. The results of his experience have been given to the world in the shape of a book, which has run through several editions, and is justly esteemed as giving practical experience instead of theoretic ideas. Sir D. Salomons has done good scientific work in other directions, but to us his personality and his tastes tend more to electrical matters than elsewhere. We trust that the Institution will recognise all he has done for electrical progress by electing him in due order to the presidential chair.

THE CRYSTAL PALACE EXHIBITION.

A generation has come and gone since the Crystal Palace became one of the institutions of England. Of the hundreds of thousands who annually enter its doorways but a small percentage know aught of the history of the edifice. In prospect, therefore, of the interesting exhibition now about to be held within its portals, a brief history of the building may not come amiss. England owes far more to the Society of Arts than is generally credited. Its work, as a society, commenced in 1754, but its first exhibition of arts and useful inventions was not held until 1761. The interval between 1761 and 1851 saw a variety of exhibitions initiated by the society, and other societies, mainly agricultural. Probably, however, the various exhibitions held in Paris from 1797 to 1849, gave rise to the idea of an international exhibition in 1851, to be held in London. In 1848 the Council of the Society of Arts made a suggestion, which, through its then president, the Prince Consort, ultimately led to the 1851 exhibition in Hyde Park. A Royal Commission was appointed, and among its work was the selection of plans for the building. Early in 1850 the Building Committee advertised for plans, and in reply received 233 plans. Out of this number only 18 could be found worthy of commendation, and not one for selection. The committee then prepared a hybrid composition according with their own view, which elicited a storm of disapprobation. However, the executive were in a corner—time was passing, and something had to be done. Specifications were being prepared, when a fortnight before they were issued Mr. (afterwards

Sir) Joseph Paxton offered to send another plan if it would be received. Suffice to say it was received, and in the end adopted, giving rise to a building which silenced critics and stamped the author as a constructive genius of the highest rank. The plans when published gave universal satisfaction, but the building itself elicited enthusiastic admiration. It looked like the palace of some genii, so ethereal was its appearance. Only iron, wood, and glass was used in its construction. In form a vast parallelogram 1,851ft. long and generally 408ft. wide, but 456ft. wide in the widest part. To this structure the name Crystal Palace was given by common consent. In it the 1851 exhibition was successfully held, and at its close there was a general desire that the Crystal Palace should not be destroyed. Many wished it to become a permanent building in Hyde Park, but that was not to be. A company was formed to purchase the materials of the building, remove, and re-erect it elsewhere. This company obtained 171 acres of land from Mr. Leo Schuster at Penge Park, and 178 acres additional whereon to erect the building and lay out adjoining grounds. A part of this land was not required, and was sold. On the site selected the first column of the building was raised on August 5th, 1852, and the building was publicly opened on the 10th June, 1854. The Crystal Palace at Sydenham, as we know it, is not an exact reproduction of the exhibition of 1851, but a more perfected building. Unfortunately, at the present day it is partly shorn of its pristine glory, a part having some years ago been destroyed by fire. It was originally in form a parallelogram running nearly north and south, the length being 1,608ft.; with two wings extending to the east, each 574ft. long; and a railway colonnade, running from the station to the south wing, 720ft. long. The entire length of the building, therefore, is 3,476ft.—nearly three-quarters of a mile. The greatest breadth is 384ft. The palace is now terminated at each end by a "crystal tower," 284ft. high; erected for the purpose of raising water to the tanks from which the high jets of the great fountains in the lower basins in the grounds are supplied. They were not in the original plan; but they add to the symmetry of the structure, when viewed from the grounds. The elevation on that side (the east is further improved by the necessity for the erection of a lower storey, to give the building the necessary width. This necessity arose from the ground sloping down to the east; and Sir Joseph Paxton suggested that a basement storey should be formed, the roof of which should support the floor of that side of the main building. This storey is entered from the front or grand terrace in the grounds, or from the railway corridor, and access to the main building is gained by staircases at the north and south ends, and in the centre. The main building, above this basement, consists of a grand central nave, two side aisles, three transepts, and the north and south wings. The dimensions of these various parts will be seen in the following table:

	Nave.	South Transept.	Central Transept.	North Transept.	Wings.
Length	1,608ft.	336ft.	384ft.	336ft.	574ft.
Breadth	72ft.	72ft.	120ft.	72ft.	—
Height from the floor to the springing of the arch	68ft.	68ft.	108ft.	68ft.	68ft.
Height to the crown of the arch	110¼ft.	110¼ft.	174¼ft.	110¼ft.	110¼ft.
Height from the basement	—	—	202ft.	—	—

The entire roof of both the nave and transepts is a vaulted arch, that of the Central Transept being 120ft. span. Between each end, and the North and South Transepts, the distance is 144ft.; and between each of those transepts and the Central Transept is 528ft. The general width of the body of the building between the transepts is 312ft. The difference between that and 384ft. is made up with glazed and open corridors. In the garden fronts of each of the three transepts are recesses 24ft. deep. "These throw fine shadows and take away from the continuous surface of plain glass walls; while the whole general arrangement of the exterior, the roofs of the side aisles rising step-like to the circular roof of the nave, the interposition of low square towers at the junction of the nave and transepts, the open galleries towards the garden front, and the long wings stretching forth on either side, produce a play of light and shade, and break the building into parts, which, without in any way detracting from the grandeur and simplicity of the whole construction, or causing the parts themselves to appear mean or small, present a variety of surface that charms and fully satisfies the eye."

The Crystal Palace, then, is *par excellence* the home of exhibitions, and no better building could have been selected for an electrical exhibition. During the 10 years since the last was held in this building great progress has been made, and it is to be hoped the forthcoming exhibits will sufficiently illustrate the present position of the industry.

PROGRESS AT THE EXHIBITION, DEC. 31ST.

We give below a list of the exhibitors at the Crystal Palace Electrical Exhibition, and some preliminary notice may be welcome of how the work of installing the machinery is progressing, with some little foretaste of what visitors may expect to see.

In the first place, we must state that the opening, originally fixed for the 1st of January, has been put off until the 9th, and indeed it is hard to see that the exhibition will be ready to open even upon that date, though a week or ten days makes a wonderful difference in the appearance of an exhibition at the time of opening. At our visit on Wednesday we found hundreds of workmen engaged in putting down machinery and erecting stalls, yet so vast is the interior of the Crystal Palace that no very great inconvenience is noticeable to the promenaders.

The exhibits may be divided into four large sections: First, the main building, down the centre of which from fountain to fountain run a row of large stalls by the great firms—Crompton, Brush, Johnson and Phillips, Siemens, Laing-Wharton, National Telephone Company, General Post Office, Edison-Swan—flanked by numerous smaller exhibits. Second, we have the Machinery Hall, with a magnificent collection of machinery in motion, by some of the same firms, together with Messrs. Davey, Paxman, and Co., and gas engine makers, with Crossley's, of course, conspicuous. Thirdly, there are the galleries, in which a number of rooms are being fitted up with art furniture, and luxuriously furnished with electric light in all artistic shapes—here Messrs. Rashleigh, Phipps, and Dawson are intending to show something astonishing, and Messrs. Cooper and other art decorators are spending large sums in providing beautiful interiors. Lastly, there is a special court in which the railway companies show the signalling systems. There will doubtless be other divisions of the principal features as the exhibition gets into shape, but these seem to be the general features as at present being prepared.

Coming into the Centre Transept, a large stand of Messrs. Johnson and Phillips will first be seen divided into two departments—telegraph and electric light. Huge cable buoys, some crushed from the weight of water at the bottom of the sea, together with grapnels and paying-out apparatus, illustrate cable laying, while the dynamos and Brockie-Pell arc lamps are being rapidly got into place. The handsome lampposts erected at St. Pancras will be shown. Very noticeable will be the two systems of mast for groups of arc lamps shown respectively by Messrs. Siemens and the Brush Company, the former a lattice mast and the latter an immense riveted tube-mast. The Brush Company have a series of dynamos and engines, baby to giant machines, in place. The General Electric Company will be very popular, for besides their switches and general fittings, they will show motors in work and electric heaters for saucepans, curling-tongs, and flatirons. Messrs. Crompton and Co. are well represented, and have several exhibits. Indeed, one seems to see Crompton, Brush, and Siemens everywhere about the place. Messrs. Crompton have one stand for dynamos and motors and arc lamps, with another for a travelling electric crane, to be shown in operation, besides their machinery exhibit. The Electric Stores, Limited, have a large centre stand.

Coming back to the centre of the Transept, Messrs. Rashleigh, Phipps, and Dawson have a large kiosk to be

fitted up as living-rooms, which will make a good show. This exhibit, we hear, is constructed so that it can be afterwards sent over to Chicago. The National Telephone Company are evidently laying themselves out to amuse and instruct; a handsome building is fitted up as a working telephone exchange, with subscribers in the Palace, an immense group of roof insulators overshadowing it. To one side are fitted up half-a-dozen public call-boxes, by which anyone will be able to talk to subscribers in London, while, perhaps, the feature of this branch of the exhibition will be a telephonic concert-room to hold 50 people, where concerts in Manchester, Liverpool, or Birmingham can be heard at charges of 3d. or 6d. for 10 minutes. The Western Electric Company are also fitting up a comprehensive telephone exhibit, being something out of the usual style.

A fine stand will be that of Woodhouse and Rawson, Limited. Already the Kingdon dynamo is in place; Midget arc lamps are being fitted up, and a novelty in the shape of an electro-hydraulic rivetter will attract attention. One of the most prominent exhibits is a church built quarter size, fitted with lightning conductors—whether the disastrous effects of lightning strokes to unprotected buildings will be illustrated does not yet appear.

The most noticeable feature of this exhibition will most certainly be the exhibit of the Edison-Swan Company, who have devised a novel and striking form of drawing attention to the lamps. High from the roof of the Palace hangs an immense number of wires, forming a kind of screen across the space. This screen is wired for electric lamps, and the whole will be covered with incandescent lamps in different sizes and colours, and in varied designs. The screen is to contain 5,000 lamps, half of which are to be used for lighting, and by means of a commutator the various devices will be shown forth in light. As much as 200 h.p. will sometimes be used to light this screen. Below this exhibit are long tables of H.M. Post Office, on which telegraphs of various sorts will be shown in operation.

Down the side arcade we notice the stalls of the Mining and General Electric Lamp Company, Lacombe's carbons, Arcas plating already in operation, Pyke and Harris's high-tension apparatus, Davis and Timmins's nuts and screws, Mr. J. Pitkin's instruments, Mosses and Mitchell vulcanised fibre, Dorman and Smith for switches, Mr. H. Sharpe, of Theobald's-road, with fittings, Blackman's air propellers, besides many others rapidly coming into shape. We should not forget to mention an electric lift, which is being arranged to raise persons from the floor to the gallery.

One of the unfortunate results of the recent fire at Messrs. Laing, Wharton, and Down's has been to throw them all behind with their exhibit. Switchboards and artistic fittings, to the extent of many hundreds of pounds, were prepared, and they were congratulating themselves upon being one of the earliest upon the scene, when the fire occurred, and the whole had to be prepared over again. Messrs. Laing, Wharton, and Down have the whole of what is known as the Entertainment Court. They will remove the stage and fit the room up as a self-contained plant, working together with Messrs. Crossley Bros., who have two Otto gas engines already fixed.

In the Machinery Hall, which lies just behind the Entertainment, whole groups of men are at work till late every night. Messrs. Siemens are perhaps the most forward. They have two huge dynamos, apparently those used in the Naval Exhibition, with switchboards ready fixed. The Brush Company have a series of vertical engines, made at their Falcon Works, being erected to drive alternators and arc machines. Messrs. Crompton have also a large space in the Machinery Hall for engines and dynamos running, the foundations for which are laid. Besides this, Messrs. Davey, Paxman, and Co. are erecting some large engines to drive Crompton dynamos. The firm of Easton and Anderson, who have recently joined the ranks of electrical engineers, are preparing an exhibit here. The Electric Construction Company have not much ready as yet, but no doubt their show will be prominent.

There will be a larger installation of gas engines than has been hitherto seen at exhibitions—the makers evidently laying themselves out to catch such contracts as are thought of for Leicester and elsewhere, where the interests of the electric light company and the local gas company will be united by driving the dynamos by gas. Besides the noticeable display of Crossley Bros., the National Gas Engine Company have a set of plant practically complete. There is an immense Wells gas engine, which will attract notice, and a whole series of Griffin gas engines, Stockport gas engines, and other makes. In the boiler-house Messrs. Davey-Paxman have seven large locomotive boilers in place. As to the rest of the machinery, the Gulcher Company, who, as is well known, now light the Crystal Palace, are taking out all the old machinery and installing new plant, which is to serve as their exhibit at the same time as lighting the Palace. They will have two 40-unit dynamos supplying incandescent and arc lamps on the low-tension parallel circuit, and a 30-unit alternator of the newly-designed Fricker type. These will be driven by the Galloway boilers and the Crystal Palace engines.

Upstairs in the galleries by far the most noticeable exhibit will be that of Messrs. Rashleigh, Phipps, and Dawson, who have probably the largest space in the exhibition. The firm are working in conjunction with the well-known decorators, Godfrey Giles, and Co., of Old Cavendish-street, and the exhibit is being fitted up in very handsome style as living-rooms and conservatory, a small army of men being constantly at work on it. The first room will be a conservatory, built up in a new kind of patent glass hollow bricks. The rockery is being carried out by Mr. Dick Radclyffe, with real rock from Robinson Crusoe's Island. The second room is an Old English hall, and the third an Italian dining-room, while the last is a Japanese drawing-room. Some novel and striking electric light effects will be introduced, and it can be confidently prophesied that this exhibit will be exceedingly popular.

Other beautiful art furniture exhibits with electric light effects will be those of Messrs. H. and J. Cooper, of Great Pulteney-street; Messrs. Allen and Menooch, of Brook-street; and Messrs. W. Wallace and Co. An exhibit of a new kind of underground creosoted wood conduit is already in place by the Macdonald Electric Subway Company, evidently of America; and Messrs. F. Wiggins and Co. will have their mica in full view. Electrical engineers who think that the exhibition will be devoted to their interests will probably be somewhat astonished to find our advertising electropath, Mr. C. B. Harness, very much to the front, intent on riding into the credulity of the public upon the crest of the electrical wave. A whole set of "electropathic treatment rooms" will be in active operation, and a very handsome set of rooms they promise to be. While so little is known about electricity, and all its ways are as "caviare to the general," the "general" will no doubt believe their petty ailments can be cured by the wagging of a needle or the sparks from a huge induction machine, especially if driven by an electric motor. The last exhibit we must now mention is that of the theatre, where the Christmas pantomime is being produced. The stage is being lighted by 300 lamps by Messrs. Rashleigh, Phipps, and Dawson, and the fairy lamps are supplied by the Mining and General Electric Lamp Company.

The public are now becoming rapidly educated in things electrical, and better able to appreciate the uses of the mysterious force. Exhibitions such as this to be opened at the Crystal Palace, serve continually to bring the actual applications of electrical science closer and closer home to both private customers who desire the latest refinements of comfort for their houses, and those, such as engineers, who are constantly on the look-out for means of increasing the efficiency of their manufactures. There is a final point we should like to insist upon here. Exhibitions too often suffer from a want of sufficient description by cards or labels in full and explicit terms attached to the exhibits themselves. Stall-keepers cannot be on the ground all the time; people, moreover, are modest and do not like to intrude too much, and yet are ever avid for information. If this is plainly and prominently set before them, with explanatory details as to theory and application and so forth upon each machine, the exhibition can be made of far greater usefulness all round.

ALPHABETICAL LIST OF EXHIBITORS.

A.	Stand No.
Appleton, Burbey, and Williamson	17, 70
Andrews, J. E. H., and Co.	64, 162
Acme Electric	110, 170
Aubert, M.	125
Allsop and Co.	132
Anderson, R.	166

TELEPHONE INSTALLATION.

Mr. Langdon, the telegraph superintendent of the Midland Railway Company, has lately installed a complete telephone system at The Adelphi Hotel, Liverpool. The installation comprises three floors, and on each floor is a switchboard for 70 directions—making a total number of 210 stations. Each room is fitted with a call-box and a double "Ader" instrument (magnetic transmitter), a separate call-bell and a three-contact pear-push, which is suspended near the bed, so that the visitors can ring in the usual way or communicate through the telephone. The visitors are able to communicate with one another and with the staff of the hotel, this effecting considerable saving of time both for visitors and staff. This installation has given great satisfaction, as it is simple and thoroughly reliable. It is similar to the large installation at The Terminus Hotel, Paris, where 350 rooms are connected, the only difference being that in the latter "Ader" microphones were used instead of magnetic transmitters. The instruments and appliances for the above installation were supplied by La Société Générale des Téléphones.

PHYSICAL SOCIETY.—Dec. 18, 1891.

Prof. W. E. Ayrton, F.R.S., president, in the chair.

Mr. R. W. Mond, F.R.S.E., was elected a member of the society.

The **President** announced that it had been found necessary to alter the dates of the meetings to be held after Christmas from those already published to the following: January 22nd, February 12th and 26th, March 11th and 25th, April 8th, May 13th and 27th, June 10th and 24th.

A "**Note on Interference with Alternating Currents**" was communicated by **Mr. M. H. Kilgour.** Whilst studying Dr. Fleming's paper on "Some Effects of Alternate-Current Flow in Circuits having Capacity and Self-Induction,' the author constructed some additional curves. He was thereby led to investigate whether the serious rises of pressure produced by adding capacity would occur over considerable ranges of capacity, or whether they would only take place when the capacity was nearly equal to a particular value. Taking the case of a condenser of capacity C farads, in series with a circuit of resistance R ohms, and inductance L henrys, he showed that the maximum value of λ (the ratio of the pressure across the condenser terminals to that across the condenser and inductive resistance) is obtained when $C = \frac{L}{R^2 + p^2 L^2}$ (1), where $p = 2\pi$ times the frequency. The maximum of λ produced by this capacity being given by the expression $\Lambda = \frac{\sqrt{R^2 + p^2 L^2}}{R}$ (2). Taking R = 10 and $p = 2\pi$, 1,000 curves plotted from equations (1) and (2) between C and L, and between Λ and L had been drawn. The C L curve rises to a very sharp peak at L = ·0015 and falls rapidly. That between Λ and L starts horizontal and bends upwards, and approximates to an inclined straight line for values of L greater than 0·002, when L = 0·1, Λ = 63. Considering the question of the range of capacity with which a given rise of pressure can occur, it was pointed out that when the values of L, R, and p are such as to make a large rise possible, a rise exceeding a moderate value can only be obtained for values of C differing little from that given by equation (1). On the other hand, when the circuit is such that the maximum rise possible is not large, then a rise exceeding a given moderate value can be obtained over a much wider range of capacity. Hence, the author concludes that the larger the possible rise the smaller is the probability of a serious rise occurring. The effect of shunting the condenser by a circuit of resistance, r, and inductance, l, is next dealt with in the paper, and the values of C which make λ a maximum determined, as well as the maximum value λ can have. Subsequently the author examines whether the practical case of an alternator feeding a transformer through a concentric cable may be simplified without introducing serious error by assuming the capacity concentrated at either end of the cable, and concludes that in ordinary cases little error will be thus made. In an experiment made with a 100-kilowatt alternator, three-quarters of a mile of $^{7}/_{16}$ concentric cable, and an 18-kilowatt transformer, a rise of ¼ per cent. was found to occur at the terminals of the alternator when the cable was connected. Putting on the transformer unloaded or loaded produced little change in the rise of pressure; this in all cases being between 0·2 and 0·3 per cent. **Dr. Sumpner** asked whether the conclusions as to the range of capacity with which a given rise of pressure was possible, was true for small rises such as occur in practice. Cases where the maximum possible rise was of the order 63 were not likely to occur at ordinary frequencies. The highest rise he had ever known was 11. He thought the time-constant of the inductive coil chosen—viz., $\frac{1}{15}$ of a second—was very large. In circuits containing iron it was practically impossible to get such large time-constants, for the power spent in the iron increased the effective resistance. Referring to the narrow range of capacity within which large rises were possible, he pointed out that such cases were found in Hertz's resonators, where the rises were immense, but to obtain them the adjustments had to be very accurately made. **Dr. S. P. Thompson** said he regretted that Prof. Fleming was not present, for he had recently investigated Hertz's experiments and had obtained curves very similar to that got for the Deptford mains. The curve between Λ and L was very interesting. It was, in fact, a curve between the secant of the angle of lag and L, as could be seen from formula (2). In practice one would be working on the lower portion, and hence the rises would be small. **Mr. Kilgour** explained that in the paper his first object was to show that the product of the range of capacity between which a rise greater than a given value would occur and the maximum possible rise, was approximately constant for different circuits. Secondly, he wished to prove that the capacity of concentric cables could be assumed to be localised at either end without introducing much error in the rises of pressures calculated therefrom. **Dr. Thompson**, speaking of nomenclature, regretted that the word inductance should be used sometimes for L, and at other times for L p, and thought its meaning should be restricted to the latter. **Prof. Perry** said a name was needed for coefficient of self-induction. Resistance was practically independent of frequency, and "inductance" should have no reference to frequency. **Dr. Sumpner** thought it important to have a name for L p, for that quantity comes into calculation most frequently. He would have preferred that "inductance" should mean L p, but Mr. O. Heaviside, who introduced the term, had used it for L. The **President** remarked that some time ago Dr. Sumpner and himself felt the need of a name for L p, and thought of using "inductance," but on referring to Mr. Heaviside's articles found it used for L. **Dr. C. V. Burton** asked whether the word "self-induction" could not be used as an abbreviation for "coefficient of self-induction." **Dr. Thompson** pointed out that this word already had a meaning—viz., L multiplied by current. **Dr. Burton** then suggested that inductivity might be applicable. **Dr. Thompson** said the word "impedance" was also used ambiguously, for the sense in which Dr. Lodge uses it in his "Modern Views of Electricity" is not the same as the vector sum of R and L p. **Prof. Perry** recalled the fact that "impedance" had been defined by the committee of the British Association as the ratio $\frac{\text{effective voltage}}{\text{effective current}}$. **Dr. Thompson** said this definition was only applicable to periodic currents, and not to intermittent or transient ones. The **President** said he understood the first object of Mr. Kilgour's paper was to enquire whether the dread of rise of voltage occurring when concentric mains were used, need exist. When Dr. Fleming's paper was read, the general idea was that concentric cables were dangerous. In the discussion on it, he, amongst others, had pointed out that the chance of a large rise of pressure was not a serious one. Mr. Kilgour had now shown that the range of capacity over which a particular rise could occur, is inversely proportional to the maximum rise possible in the particular circuit. When the circuit was such that a large rise was possible, the probability of any serious rise taking place was very small, hence the fears of large rises were more or less unfounded. The second part of the paper was to show that ordinary problems on concentric cables could, in practical cases, be treated with sufficient accuracy by assuming the capacity localised at either end of the cable, instead of distributed along its length.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With this copy of the Paper is issued a Supplement containing a sketch of the scene at the Institution dinner, by W. M. BOWLES, with six portraits, taken from photographs, of **Prof. W. Crookes, F.R.S., Prof. W. E. Ayrton, F.R.S., General Webber, C.B., Mr. W. H. Preece, F.R.S., Mr. F. H. Webb,** and **Sir D. Salomons.**

Every reader should see that he gets this Supplement, and non-delivery with the Paper should be reported at the Publishing Office.

1892.

TO ALL READERS, A HAPPY AND PROSPEROUS YEAR.

Egoism is an article as common as jingoism, hence we may be permitted to claim a little of it, and in the first place speak of ourselves. We claim to pay attention principally to business matters, leaving our contemporaries to discourse on transcendental questions about which no one knows anything in particular, though it pleases them to consider otherwise.

THE DIRECTORY.—The new feature of a weekly trades' directory, introduced to-day, may or may not be of service. At any rate, correspondents from widely different quarters are continually asking for names of firms and men, and it seems to us that while an annual directory well done may be valuable, a weekly directory equally well done will be invaluable. The large directories are limited in circulation, and are partially out of date even at the time of issue. The weekly directory can be corrected every seven days, and must in a short time be fairly trustworthy. The directory we issue to-day is not put forth as perfect—it is tentative only; and we ask our readers' assistance to make it more complete. Utility is required, not mere lists of names and addresses. This is how the matter strikes us as business men. Take one example—electrical engineering. It is extending, installations are increasing. By and by each installation will require periodically a replenishing of stores. The oil merchant, the wire manufacturer, the carbon-rod manufacturer, the incandescent lamp manufacturer, and so on through the whole gamut of trades, send representatives to call upon the officers in charge of installations for "orders." It may suit some of the big makers to fancy they will hold the trade because now they are going on swimmingly. They will have to take the small with the large, and remember "many a mickle makes a muckle," or competition will ultimately leave them without the mickle. In another direction, again, we may urge the benefit of a weekly directory. Readers in Australia, New Zealand, South Africa—aye, even in England, Scotland, and Ireland—have never seen, and are not likely to see, the more pretentious works, yet require certain information. This information they get from the paper, communicate with one or more firms, and business results. Wherever the paper is seen—and it is astonishing where papers are seen—the name on the list gets publicity. It would be altogether too much of the confidence trick to insinuate that our views are entirely for the benefit of our patrons. Not so; we believe in mutual advantage, and have no reason to fear but the effort to do something for the benefit of readers will also redound to our own benefit.

PORTRAITS.—From time to time, in a more or less desultory manner, portraits have been given in various papers, but hitherto nothing has been done in a systematic manner. We venture, then, to commence systematically what has hitherto been

done sporadically. With this issue we give half-a-dozen portraits obtained from photographs, and we have another twenty or so ready for insertion at convenient opportunities. One of the great aims of telegraphists is to find a good way of sending plans, portraits, and pictures telegraphically. We cannot hope to emulate inventors, but follow behind: call in the photographer, engraver, and printer to assist to distribute as widely as our paper is read the representative features of representative men. To obtain a favourable result we require a good, bright photograph, and hope by these means to enable readers who may never be acquainted with prominent men in the flesh to have some idea of what they look like. Had similar views held in the time of Sturgeon and similar means been ready to do the work, we should not now be deploring the loss of his portrait.

THE PAST YEAR.—Several important questions are raised by the work of the past year, but our usual general comments thereon must be reserved for the present. The old year has only just fled, that many who usually favour us with their views have not yet—or too late, owing to the holiday season—placed them in our hands. Meanwhile, we commence to give a *résumé* of the work of individual firms.

ELECTRIC CONSTRUCTION CORPORATION, WOLVERHAMPTON.—In addition to a large and continually increasing amount of business in the supply of machines, switchboards, etc., for private installations, this corporation has carried out some large contracts for continuous-current machines for central lighting stations in London, etc., also some exceptionally large copper depositing plants. They have built a number of the Elwell-Parker alternating-current machines, and supplied large numbers of transformers. They supplied the switchboards and accumulators for the St. Pancras Vestry installation, which has been at work since November last. A somewhat new feature of the past year has been the rapid development of continuous-current transformers. Large central station plants on this system are at the present time being supplied to Messrs. J. E. H. Gordon and Co. for the Installation and Maintenance Company's station at Sydenham, and also for the Oxford Electric Light Company. In addition to these they have supplied continuous-current transformers to other stations. The corporation had completed the electric transmission of power plant in its new works, at Wolverhampton, where all the machine tools, cranes, etc., are driven by means of motors. In addition, they have supplied a number of motors for various purposes, including a set of 60-h.p. hauling plant, and some machines for driving pumps, etc., in collieries. Amongst other important work in hand for the coming year is the contract for supply of generating plant, rolling-stock, and conductors for the Liverpool Overhead Railway.

ELECTRICAL STANDARDISING, TESTING, AND TRAINING INSTITUTION.—During the earlier part of the year some time had to be spent fitting up the new premises, Faraday House, Charing Cross-road, under the superintendence of the heads of the various sections. The standardising and testing departments have had continuous work since they were opened, and as manufacturers and others are getting to find that their instruments can be standardised and calibrated more efficiently at the institution than at their own works, this branch of the business steadily increases, though some firms prefer hiring a private room and doing their own work, the institution supplying apparatus and current. A good deal of work has also been done by experimenters who rent the private rooms, and borrow the apparatus as they require it. Much has been done in the direction of inspecting and reporting upon private installations, testing meters, etc., in cases where disputes have arisen between householders and their contractors or supply companies. Dynamo machines, steam engines, and apparatus generally have also been inspected at the manufacturers to see if they fulfil the specifications, but this work has been chiefly done for agents who are sending plant abroad. Indeed, the necessity for the new departure made when the institution was founded has been clearly shown by the connection already made. In the training department some 50 names are on the books, and it is satisfactory to learn that the companies and firms in affiliation with the institution have already drawn upon it for assistant engineers, the companies usually keeping those apprentices who have been sent them for the purpose of being practically trained and who have shown themselves specially apt for their work. The forthcoming competition for the scholarships and exhibitions seems likely to be large.

INDIA RUBBER COMPANY, SILVERTOWN.—This company has been fairly busy in every branch throughout the year, and in the electrical departments some important orders have been carried out. The cable department laid along the West Coast of South America 1,750 knots of submarine cable for the Central and South American Telegraph Company. Over 1,600 knots of cable have been made and laid along the coast of Brazil for the Western and Brazilian Telegraph Company. Orders have also been executed for cable for the Post Office, the India Office, and various foreign Governments, and about 1,100 knots of a cable to be laid next year between West Africa and Brazil have already been manufactured. The cable department has, in addition, delivered a large quantity of torpedo and electric light cable for shipping orders. For low-tension house-lighting cables and wires the demand still increases, and for high-tension distribution considerable lengths have been manufactured for the Metropolitan Electric Supply Company, the House-to-House Electric Supply Company, the City of London Electric Company. Newcastle-on-Tyne and other towns in England have been large consumers. The company's French factory has filled several orders for the lighting of Paris, Madrid, Barcelona, Tours, Havre, etc. The Admiralty, as a result of past experience, has decided to again adopt india-rubber insulation, and the Silvertown Company, in addition to the Government contract for the year, have obtained a number of orders from the various firms carrying out Admiralty contracts. The instrument department, besides railway, Post Office, and Admiralty work, have executed a number of shipping orders for telegraph and torpedo instruments, and has supplied the whole of the new station switch gear for the London Electric Corporation. The battery department has throughout the year been full of orders, especially for Leclanché cells, which have been supplied in large numbers to Government, and to railway and supply companies. In the electric light department a fair amount of work has been done, including the supply of dynamos and the fitting up of electric light and signal gear on a number of H.M. ships, amongst others the "Blenheim,"

"Blake," "Royal Sovereign," "Grafton," "Theseus," "Repulse," and "Empress of India. Installations of electric light in factories, mills, mines, and private houses have also been carried out, and large number of complete sets of dynamos, cables, fittings, etc., for installation abroad have been delivered. In transmission of power an important order has been executed for a tramway on the Continent, comprising eight cars, which have been in operation for the whole of the summer season. The results obtained are so satisfactory that an additional order has been received for equipment of six 25-h.p. cars, and for the supply of necessary machinery at the station for this extension. In the smaller electrical branches there has also been a good demand.

Paterson and Cooper.—Messrs. Paterson and Cooper have been well employed during the whole of the year, and exceedingly busy during the latter part. As in previous years, shiplighting has furnished a considerable portion of the business, and among the vessels fitted up in 1891 have been the "Nottingham," "Staveley," "Leicester," and "Lutterworth," new steamers of the Manchester, Sheffield, and Lincolnshire Railway Company; the "City of London," "City of Agra," "City of Khios," "City of Edinburgh," and "City of Dublin," belonging to G. Smith and Sons' City Line; "St. Nicholas" and "St. Sunniva," belonging to the North of Scotland, Orkney, and Shetland Company; also the "America," "Berlin," "Furnessia," "Killarney," "Empress of the East," and several others, including the steam yachts "May," "Pathfinder," and "Hermione." The firm has presently on hand the lighting of steamers for the Allan Line, for the General Steam Navigation Company, and for the Clyde Shipping Company. In all manufacturing departments the business has been good. The dynamos have averaged much larger sizes than in previous years, mainly on account of a large number being directly coupled to the driving engines. For machines of large output coupled to double-acting engines the multipolar design is adopted, both Gramme and drum windings being used for the armatures according to circumstances. In arc lamps a good business has been done, a large number having been sold for use on alternating as well as on direct current circuits. The sales in measuring instruments have been well kept up, and the trade in switchboards, fittings, and accessories has considerably increased. During the year complete installations have been erected at the Lancaster Waggon Company's Works, at Bullionfields Paper Mills, Invergowrie; at the residence of G. Peters, Esq., High Elms, Watford; and at Corona, Broughty Ferry, the residence of R. A. Mudie, Esq., the well-known shipowner. Installations of arc lamps have also been completed at the shops of Mr. Lipton, in Dublin, Birmingham, Southampton. Deptford, and London (Edgware-road). Of the wiring of private houses for supply from the various supply companies' mains the firm has had a good share, while among the large establishments wired and fitted may be mentioned Messrs. Combe's Brewery, Messrs. Lambert and Butler's Warehouse, and the St. George's Club, Hanover-square. The firm has several contracts still in hand, the largest being the lighting of the *Daily Chronicle* and *Lloyd's News* offices in Fleet-street, and the refrigerating stores and wharf of Messrs. Nelson and Co. at Lambeth. The former is being wired for 800 16-c.p. and the latter for 1,600 16-c.p. lamps, and both installations will include direct-coupled dynamos and engines complete. For the *Daily Chronicle* offices the dynamos are two in number, with 24in. Gramme armatures, running at 300 revolutions in a four-pole field, and directly coupled to vertical engines 13½in. cylinder and 10in. stroke, made by J. and H. Gwynne. For Nelson's wharf the dynamos, two in number, are also four-pole, and have 25in. drum armatures, running at 200 revolutions, directly coupled to double-crank compound engines. The engines are made by Messrs. J. and H. Gwynne, for whom the installation is being carried out, and have 8½in. and 16in. cylinders with a stroke of 14in.

Robey and Co., Lincoln.—During the year there has been an active demand for engines for electric lighting purposes, not only for isolated installations, but for large central stations. Electricity seems dividing itself now sharply into two classes—viz., independent installations of moderate extent for individual consumers just needing the care of one man to look after them, and in many cases worked by gas engines; on the other hand, large central stations of great extent, taking in an entire town or district. The medium installation worked for a number of customers in a comparatively small district seems, so far as the experience of this firm goes, to be undergoing the process of elimination. Dynamos are increasing in size, as considered by output, and the class of engine most successfully used are those from 200 h.p. to 500 h.p. indicated, which work an independent dynamo. Of this class this firm has made large numbers. Where space is available, and even where it had to be paid for dearly, it is found most economical to use long-stroke horizontal engines worked at high piston speed, but a moderate number of revolutions, and each driving its own dynamo through rope gear. In the Newcastle Electric Light Supply Company's installation (which is one of the largest in England) there are three engines which work to about 200 h.p., duplicates of each other, and Messrs. Robey have just supplied a fourth which will work to about 500 h.p. The size is thought to be one which will be largely used in the future, and will, perhaps, be the most economical for driving a single machine. The reason for suggesting this as a maximum power, is because in cases of accident to either dynamo or engine it is as large a unit in an installation as ought to be thrown out of gear at once, even if it be not too large. For confined situations high-speed vertical compound engines are now being extensively used, and four of these have recently been supplied for the street lighting in London, the two smaller ones being about 100 h.p. and the two larger 200 h.p. each. These larger engines will work easily up to 170 revolutions per minute, and dynamos might be built to couple direct and run at that speed. In the London installation, however, they are being driven by belt, but as there is not a large difference between the size of the driving wheel on engine and the pulley on the dynamo, the belt centres can be kept shorter, and the whole space occupied is very much reduced. Replying to a definite question relating to central station work, Messrs. Robey and Co. say: "The important points, we think, which should be taken into consideration in central station work are the size of the unit of distributing machinery and the method of distribution. As above stated, we think each engine should drive its own independent dynamo, and that all countershafting and gearing connecting one with the other should be dispensed with, and that, with the exception of one smaller engine for running a few lights during the daytime or the small hours of the morning, the engine and machines should be duplicates of each other, with at least one spare one of each. The method of dis-

tribution which seems growing in favour is that of high-tension alternating-current, with transformers. Instead of transformers in every establishment where the light is used, what will probably be found more economical and convenient will be to have transforming stations for a large district. Another matter upon which much has yet to be learned is the construction, insulation, and especially the laying of the cables." Special attention is called to the Newcastle Electric Supply distribution, where Messrs. Robey's engines are used in connection with Mordey alternating-current machines, where the current is being supplied at what is believed to be the lowest price in the kingdom, and probably in the world—viz., at 4½d. per Board of Trade unit. An installation which can do this and make a commercial success of it is one worthy of attention, and the method adopted therein is worthy the study of all parties interested in electric distribution. This firm, it is well known, still continues to supply large numbers of engines both for private and central station installations for the Continent and other parts of the world.

CORRESPONDENCE.

"One man's word is no man's word
Justice needs that both be heard.'

TELEPHONING AT SEA—THE WORD "TELEPHONE."

SIR,—I would suggest that the late Mr. Stuart's "sea telephone" (see p. 579 of your last volume) was nothing more than a method of conveying signals at sea by the agency of sound. In January, 1828, a M. Sudré presented to the Academy of Fine Arts in Paris a system of transmitting words by means of musical sounds, which he called "telephony." It was the subject of extensive experiments, both in the French navy and elsewhere, an account of which may be found in the *Mechanics' Magazine* for July, 1835, p. 269. The inventor visited England in that year, and he explained his method at a meeting of the Royal Society. As an illustration, it may be stated that the word "age" would be transmitted by playing on a trumpet or other instrument the notes *la* (a), *sol* (g), and *mi* (e). In July, 1884, Captain J. N. Tayler, R.N., showed a foghorn, which he called a "telephone," at the Admiralty. The following extract from a newspaper of the day shows what this "telephone" was:

"At an Admiralty *levée*, last week, Captain J. N. Tayler's telephone instrument was exhibited to the Lords Commissioners. The chief object of this powerful wind instrument is to convey signals during foggy weather, when no other means presents itself, by sounds produced by means of compressed air forced through trumpets, which can be heard at a distance of six miles. This important instrument will tend to prevent collision at sea and on railways, and will lessen the horrors of shipwreck and capture, and give notice of fire. Vessels in the offing will be by it directed into harbour, and the time to enter tide harbours made known from the pier-head. Four notes are played by opening the valves of the recipient, and the intensity of sound is proportioned to the compression of the internal air. The small-sized telephone instrument, which is portable, was tried on the river, and the signal notes were distinctly heard four miles off."

The word was used in another sense by Prof. Wheatstone, who says, in his reply to Cooke (W. F. Cooke, the *Electric Telegraph*, 1857, p. 114): "When I made in 1823 my important discovery that sounds of all kinds might be transmitted perfectly and powerfully through solid wires, and reproduced in distant places, I thought that I had the most efficient and economical means of establishing a telegraphic (or rather a telephonic) communication between two remote points that could be thought of. My ideas respecting a communication of this kind between London and Edinburgh you will find in the *Journal* of the Royal Institution for 1828. Experiments on a larger scale, however, showed that the velocity of sound was not sufficient to overcome the resistance and enable it to be transmitted efficiently through long lengths of wire."

I cannot find the paper referred to in the *Journal* for 1828. That for 1831 is the volume in which the paper appears.

In his answer to the above, Cooke says, at p. 260: "In the meantime, the failure at Portsmouth left his [Wheatstone's] submarine conception (with his telephone) in abeyance."

Perhaps some of your American readers will make enquiries about Mr. Stuart's "telephone" and communicate the result to the *Electrical Engineer*.—Yours, etc.,

R. B. P.

ELECTROLYSIS OF GOLD SALTS.

BY ALEXANDER WATT.

In pursuing a series of experiments in the electrolysis of solutions of salts of gold, it was resolved not alone to determine the behaviour of various gold salts under the influence of the electric current, which had received but little attention in an electro-chemical sense, but also to ascertain whether certain other saline substances when subjected to electrolysis in the presence of a gold anode could cause the metal to become dissolved and to enter into the solution. It was the writer's desire, moreover, to see if a solution of gold could be formed in which articles could be electro-gilt of a good deep gold colour when worked at the ordinary temperature of the atmosphere, and thus obviate the necessity of using hot solutions for certain classes of work. It was also deemed desirable to see what modifications in the colour of the deposited gold could be obtained that might prove useful to electro-gilders for producing varied effects upon ornamental work of various kinds. In this connection it was hoped that some of the substances used as precipitants of gold from its solutions would aid the results aimed at. It should be mentioned that all the electrolytes produced by the methods described were tried in their cold state, except where otherwise specified. The current employed was obtained from one-quart Daniell cells, and if two or more cells were required they were coupled in series.

1. *Iodide of Gold and Potassium.*—A solution of this double salt was prepared by gradually adding a solution of iodide of potassium to a neutral solution of terchloride of gold, until the whole of the metal was thrown down in the form of a yellow precipitate of iodide of gold. After allowing the precipitate to subside, the supernatant liquor was poured off, and distilled water added to wash the precipitate, the washing being repeated several times. The last washing water being removed by decantation, a strong solution of iodide of potassium was next gradually poured on to the precipitate, with constant stirring after each addition, until the whole of the iodide of gold was dissolved. The solution, after being filtered, was diluted with about four volumes of distilled water, and was then electrolysed with the current from two Daniells in series, a gold plate being used as the anode and a strip of platinum foil as the cathode. The current proving insufficient, a third cell was connected, and soon after a grey deposit formed upon the platinum surface which in no degree resembled gold; when plunged into cold nitro-hydrochloric acid, however, it tardily dissolved, and its solution indicated the presence of gold, when a drop or two of a solution of protochloride of tin was added, the purple of Cassius being at once produced. A strip of silver was next used as the cathode, the same current being employed, and soon after its immersion it was noticed that a salt of a pink colour formed at that electrode, passing quickly in the direction of the positive plate, and eventually settling at the bottom of the vessel in the form of a red powder. On examining the silver plate, after some minutes' immersion, it was found that a greater portion of the deposit was of a dark grey colour and firmly adherent, while on both sides of the plate there appeared patches of a pretty pink colour, interspersed with the grey film referred to; the only tint of yellow gold appeared at the upper

surface of the back of the plate. That portion of the plate upon which the film referred to appeared was heated over a spirit lamp, when the grey part of the deposit speedily turned a rich deep blue colour, but the pink-coloured patches remained unaltered. On examining the anode the immersed surface was found to be coated with a film of iodine, which readily dispersed when the plate was held over the flames of a spirit lamp. It was subsequently found that when a silver cathode was kept constantly moved about in the solution, while the current was passing, the deposit assumed the characteristic appearance of gold, but not of a good colour.

2. *Iodide of Gold in Cyanide of Potassium.*—A quantity of moist protiodide of gold, prepared as above, was next dissolved in a moderately strong solution of good cyanide of potassium, and the solution after being filtered was diluted with about four volumes of distilled water. With the current from two Daniells, gold of a deep yellow colour deposited somewhat slowly upon a silver plate. The solution was next heated to about 100deg. F., when a fresh silver plate was immersed, which became instantly coated with gold of a fine deep yellow colour much resembling jewellers' "wet colour" gold in tone. With three cells, and the cathode kept briskly in motion, a very rich and bright deposit was obtained.

3. *Gold Protiodide in Sulphocyanide of Potassium.*—Moist iodide of gold was digested in a moderately strong solution of sulphocyanide of potassium, and after filtering and diluting with about three volumes of water the solution was tried with the current from two cells, when gold of a deep yellow colour formed upon a silver plate. A similar result was obtained when the solution was warmed, but the cathode required to be kept gently in motion to ensure a uniform film, when the metal deposited was of a very fine colour.

4. *Sulphocyanide of Gold by Electrolysis.*—A rather strong solution of sulphocyanide of potassium was electrolysed with the current from four Daniells in series, a gold anode and silver cathode being used as the electrodes. The action was somewhat slow, but in the course of a quarter of an hour or so a slight film of gold formed upon the silver plate, which assumed an indifferent colour as the deposit became thicker. An improvement, however, took place when the solution was warmed and the cathode kept gently in motion.

5. *Auroteriodide of Gold and Potassium.*—A solution was prepared by gradually adding a neutral solution of terchloride of gold to one of iodide of potassium, and the dark green solution formed was then diluted with water and electrolysed with the current from three cells. A deposit of gold, of a somewhat indifferent colour, slowly formed upon a silver cathode, and the anode was coated with a film of iodine; when this film was rubbed with the finger and white paper smeared with it, an intense blue colour immediately appeared, which was due to the formation of iodide of starch, the latter substance being used as a stiffening material in the manufacture of paper.

5. *Teriodide of Gold in Cyanide of Potassium.*—As in experiments 2 and 3, the present combination was devised in the hope that a solution would be obtained which would yield deposits of gold of good colour without heating the solution. A quantity of teriodide of gold being prepared by gradually adding a solution of the terchloride of gold to one of iodide of potassium, a strong solution of cyanide was then added, and the resulting liquid, after filtration and dilution with about four volumes of water, was electrolysed with the current from two Daniells in series, a silver cathode being used as before. The solution was at first used in its cold state, when a film of gold of a good rich colour was obtained. A third cell was next put into circuit, and the silver plate kept gently in motion, under which condition gold of a good deep tone of colour was obtained which fully equalled in appearance the gilding produced in warm cyanide solutions. A gilding bath of the composition given might be found useful in the plater's workshop.

6. *Gold Protiodide in Hyposulphite of Soda.*—A solution was prepared by dissolving recently precipitated and moist protiodide of gold in a strong solution of hyposulphite of soda, and the solution was then moderately diluted with water, and the cold solution then electrolysed with the current from two cells. A deposit of gold, of good colour, soon formed upon the silver plate, and much resembled in tone the deposits obtained in warm cyanide baths.

7. *Auroterfluoride of Potassium by Electrolysis.*—A strong solution of fluoride of potassium was electrolysed with the current from three Daniells in series; gas was freely liberated at both electrodes, and in about 15 minutes after immersion of the plates a deposit of gold began slowly to form upon the silver cathode. On examining the anode it was found that a dark orange-coloured film had formed on the immersed portion of the plate, which strongly emitted the vapour of fluorine.

8. *Auroterbromide of Potassium by Electrolysis.*—A solution of bromide of potassium was prepared by dissolving 60 grains of the salt in one ounce of distilled water. A gold anode and platinum cathode, connected with three Daniells, were then immersed in the liquid, when it was noticed that gas was freely given off at each electrode, and that a deep orange-coloured and very dense solution of terbromide of gold formed at the anode, and flowed from the plate in a continuous stream, causing the liquid to assume at first a pale yellow, and after a time a deep orange colour similar to the analogous chlorine, salt of gold. In the course of two or three minutes from the commencement, a film of gold appeared on the surface of the platinum plate, but a few minutes after the deposit acquired the dark green non-reguline character, which this metal often assumes when deposited from some of its solutions by electrolysis, and indeed, not unfrequently when precipitated from some of its solutions by chemical reaction. Respecting this green form of gold, to which reference may have to be made somewhat frequently, it is clear that although its colour and non-metallic appearance give no indication of its real metallic character, that it is, in fact, metallic gold in a highly comminuted condition, and in this state bears a close resemblance to a form of iron which the writer has frequently obtained when electrolysing solutions of persalts of that metal. The electrodes were next left undisturbed in the bath, under the action of the same current, for about four or five hours, at the end of which time it was found that a profuse spongy mass of gold had formed at the cathode and spread out until it reached the anode, when, of course, the current was stopped—the spongy mass, which was of a nut-brown colour, similar to the gold obtained in making a parting assay of the metal. Finding the solution to be too strong in metal for a gold bath, it was next diluted with about three volumes of water and was tried again with the same current as before, when a silver cathode became coated with a film of gold a few seconds after immersion, but the colour of the deposit varied considerably during the immersion of the plate. Although gilding of a very fair colour may be obtained from this solution, with care, there is some uncertainty as to the working of baths prepared with this salt, and it cannot on this account be recommended as a reliable material for making up gilding solutions to be used for practical purposes.

9. *Auroteriodide of Potassium by Electrolysis.*—A moderately strong solution of iodide of potassium was electrolysed with the current from three cells in series, a gold anode and silver cathode being immersed in the liquid. The electrolytic action was very prompt, the solution nearest the anode assuming a deep orange colour almost immediately, causing the bulk of the liquid to acquire a pale yellow colour, which deepened into a full orange tint in a very short time. In about 15 minutes from the commencement, the silver cathode was found to be coated with a film of gold of a good colour. It may be said that in nearly all respects the results obtained in this experiment resembled the preceding, except that of the two solutions the latter yielded the better coloured deposit.

10. *Auroterbromide of Ammonium by Electrolysis.*—A solution of bromide of ammonium being prepared, this was electrolysed with the current from two cells in series, when it was found that the anode, as before, became rapidly dissolved, and an orange-yellow solution produced, at which point the silver cathode began slowly to receive a coating of gold, which deepened in colour as the deposit thickened. In all respects, however, the results obtained

in this experiment closely resembled those noted in experiment 8.

11. *Aurochloride of Ammonium by Electrolysis.*—A strong solution of chloride of ammonium was electrolysed with the current from three cells, when it was found that a light brown powder of fulminate of gold formed at the anode and accumulated at the bottom of the vessel. In less than half a minute from the commencement a film of gold appeared upon the silver cathode, but in about one minute after the deposit appeared of a dense black colour. The solution was next diluted considerably, and a freshly-prepared silver plate immersed, when the deposit became more reguline, but iridescent in parts. The current was now reduced by disconnecting two of the cells, when the metal deposited in a much better condition. The solution being a very good conductor, the current from one cell was found to be fully sufficient for the reduction of the metal, a very small anode surface being also necessary to secure a good-coloured film.

(To be continued.)

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

I.—INTRODUCTORY.

It is only within the last few years that in this country the twin subjects of Electricity and Magnetism have been really promoted to the dignity of a science. Formerly the crude results obtained from electrical and magnetic experiments were to a great extent dependent upon a rude system of arbitrary and ill-defined units, which, being but imperfectly understood, were often the cause of much perplexity to the uninitiated investigator. As a result of the brilliant labours of the British Association's Electrical Standards Committee, a rational set of units was at length elaborated, and this had the effect of placing electrical investigation on a firm and sound basis. The former chaotic state of electrical nomenclature, and its correspondingly complicated system of measurement, have now passed away, and electricity, freed from the trammels which for so many years have hampered and impeded its progress, has at length entered into the region of an exact science. With our modern system of standards and units, differences of potential or electrical pressure, rate of flow or density of current, resistance to flow of current, and work performed in overcoming this resistance, may now be stated with the utmost degree of precision.

Coincident with this precise definition of the electrical units, appliances of great delicacy were constructed for their practical realisation and reproduction, and at the present time copies of all the standard electrical units may be obtained at a comparatively low cost, and of even greater accuracy than the units of mass or dimensions.

Within the last few years enormous strides have been made in the production of sensitive and reliable electricity-measuring instruments. The antiquated and troublesome galvanometers on the sine and tangent systems are rapidly being superseded by the more convenient direct-reading, and in many cases dead-beat, instruments. By the employment of simple and easily-managed current and potential measurers, the merest electrical tyro is now enabled to read off at a glance the amount of current and electrical pressure being developed by a dynamo, or the energy being consumed by one or more lamps, and to tell, by a simple arithmetical calculation, the amount of electrical energy stored in an accumulator, or involved in the transformation of a current of high intensity into one of lower and more useful electromotive force.

The aim of these articles is to describe the theoretical considerations involved in the construction of the various electricity measuring instruments, the methods employed in their manufacture, and their commercial applications.

We hold that an electrical engineer who thoroughly understands the construction of the apparatus he is using is far more likely to detect and localise any errors arising from imperfect workmanship or bad design than one who merely takes everything for granted, and who relies absolutely for his results upon a given constant or a table of equivalents. This applies to the use not only of commercial instruments, but also to those employed for purposes of calibration, and to standards.

We shall begin by defining and explaining the most commonly used electrical units, and their practical realisation and reproduction; and shall then go on to describe the various instruments to be obtained for measurements in terms of these units. Considerable attention will be devoted to the technicalities of construction of these instruments, and to the different characteristics which must be kept in view when it has been decided whether they are intended for measuring direct or alternate currents, or both. The various methods of calibration will be considered, and some special attention will be bestowed on the standardisation and re-calibration of standard instruments.

We will divide the subject of Electricity-Measuring Instruments into the different classes under which the instruments seem naturally to arrange themselves. Thus, in the first place, we have the two great classes — Non-Recording and Recording Instruments. These again subdivide into—Resistance, Potential, Current, Energy, and Capacity Measurers; and these still further into—Instruments for Direct Currents, for Alternate Currents, and for both.

In our treatment of the subject we shall endeavour, as far as possible, to confine ourselves to the essential and desirable characteristics of good and theoretically sound instruments, leaving the consideration of highly-polished metal work and æsthetically-designed outside cases—too often, alas! the only recommendation which certain classes of instruments possess—to take care of itself.

UNITS.

The three principal units used in electrical measurements are the *Ohm*, the unit of Resistance; the *Volt*, the unit of Electromotive Force; and the *Ampere*, the unit of Current; and to these may be added the *Watt*, the unit of Power or Rate of doing Work. Other units not so commonly in use are the *Coulomb*, the unit of Quantity; and the *Farad*, the unit of Electrostatic Capacity. The *Coulomb* was formerly termed the *Weber*, and in the Indian Telegraph Department the Ampere used to be known as the *Œrstedt*.

Ohm.—The unit of Electrical Resistance, the *Ohm*, is usually defined as the resistance offered by a column of pure mercury of a given section and length, and at a certain fixed temperature, to the flow of an electrical current. Unfortunately some little difficulty has arisen in assigning a definite value to the unit of Resistance, and many suggestions have been made as to what the real value of the Ohm should be. From these may be cited the Siemens Ohm, the British Association Ohm (usually written the B.A. Ohm), the Kohlrausch Ohm, the Legal Ohm, the True or Rayleigh Ohm, and the Ohm proposed by Messrs. Duncan, Wilkes, and Hutchinson, as the result of an investigation made at the Johns Hopkins University, Baltimore, U.S.A. The British Association Ohm, however, is now the one generally adopted, and, in this country at least, when the term "Ohm" is used without qualification, the B.A. Ohm is always understood.

In the second column of the following table are given the various lengths of a uniform column of pure mercury of one square millimetre in sectional area and at a temperature of 0deg. centigrade, whose electrical resistances are stated as representing the respective values of the Ohm, and in the three succeeding columns these values are given expressed in terms of (3) the B.A. Ohm; (4) the Legal Ohm; and (5) the True Ohm.

TABLE I.—RELATIVE VALUES OF THE VARIOUS "OHMS."

Description of "Ohm."	Length of mercury column 1 sq. mm. section and at 0° C.	Values expressed in terms of		
		B.A. Ohm.	Legal Ohm.	True Ohm.
	Centimetres			
Siemens Ohm	100·00	0·9541	0·9435	0·9411
B.A. Ohm	**104·82**	**1·0000**	**0·9889**	**0·9864**
Kohlrausch Ohm ...	104·93	1·0010	0·9899	0·9874
Legal Ohm	106·00	1·0113	1·0000	0·9975
True Ohm..............	106·27	1·0139	1·0026	1·0000
"Baltimore" Ohm..	106·34	1·0146	1·0033	1·0016

(To be continued.)

NEW ELECTRIC RAILWAYS FOR LONDON.

The comparative success of the existing electric railway in London has evidently given an impetus to the movement for providing still further means of locomotion of a similar kind. For consideration during the forthcoming session of Parliament there are no fewer than five Bills which propose either the construction of new electric railways or the extension of lines already authorised.

Great Northern and City Railway.

Among the most important of these is the Great Northern and City Railway Bill, which is a proposal for the incorporation of a new company with powers to construct a line of railway from the Canonbury branch of the Great Northern line near Finsbury Park to the City. The capital of the proposed company is fixed at £1,500,000, in shares of £10 each, and the works which it is proposed to execute are (1) a railway five furlongs 5·70 chains in length in the parish of St. Mary, Islington, commencing by a junction with the up-line of the Finsbury Park and Canonbury branch of the Great Northern Railway and terminating at Drayton-park, Holloway; (2) a railway one furlong one chain in length commencing by a junction with the down-line of the Great Northern Railway and terminating at the same point as Railway No. 1; (3) a railway two miles five furlongs 1·40 chains in length, commencing by a junction with the terminus of Nos. 1 and 2 railways and terminating in the parish of St. Stephen, Coleman-street, at Finsbury-pavement, opposite the north side of West-street. The method of construction proposed is similar to that adopted on the City and South London line, the greater portion being constructed in two tunnels for separate up and down traffic. The railway will be approached by means of stairs or inclines, and hydraulic or other lifts. The tunnels are to be constructed by means of steel or other sufficient metal shields, driven forward by hydraulic pressure as the work proceeds, the shields being of sufficient length to protect the whole of the soil for a reasonable distance both in front and behind the working faces. The Bill provides that the exits and entrances of the station buildings and the waiting accommodation for passengers shall be so designed and of such an extent as to secure the least practicable inconvenience to the public traffic in the adjoining streets, and plans of the stations outside the City are to be submitted to the London County Council. The period for the completion of the works is limited to five years, and provision is made for cheap fares for the labouring classes, the proposal being to run two trains each morning and evening at fares not exceeding a penny for each journey. Power is given to enter into an arrangement with the Great Northern Company to construct the line.

Islington and the City.

The City and South London Railway Company have brought in a Bill repeating their proposal of last year for the construction of a line extending their system to The Angel, at Islington. Last session the Bill was thrown out mainly because of the fact that no physical junction was provided in the City with the existing line. It is now proposed to construct a line from near the St. George's Church, in the Borough, to the northern end of the City-road, Islington, near The Angel—a distance of two miles five furlongs three chains and 50 links—and, in addition, two subways for foot passengers; the first, under the High-street, Borough, to afford an access from the underground electric railway to the London and Brighton and South-Eastern Railway stations at London Bridge; the other, under Arthur-street East, which will give access to the present electric railway at its terminus at Fish-street-hill. The mode of construction is the same as that described above, and the period named for the completion of the works is five years. Provision is made for agreements with the Metropolitan, the Metropolitan District, the Joint Committee of those railways, the London, Brighton, and South Coast, the Great Northern, and the Central London Railway for the purposes of construction, working, traffic, etc., and the City and South London Company is to be authorised to raise an additional capital of £810,000, with further borrowing powers of £270,000.

Central London Railway.

The Central London Railway Company, who were empowered last session to construct a line from Shepherd's Bush to the City, are proposing this session to extend their powers by the making of a line from under Mansion House-street, near the junction with Queen Victoria-street, to the Liverpool-street Station of the Great Eastern Railway Company. In respect of this scheme they propose to raise an additional capital not exceeding £150,000, in shares of £10 each, and to take additional borrowing powers to the extent of £50,000. The time proposed for the carrying out of the work is limited to five years, and the rates and charges are to be the same as were authorised in the Act of last session. Power is proposed to be taken to enter into agreements with the Great Eastern Railway Company, the London and North-Western Railway Company, the North London Railway Company, and the Metropolitan Railway Company for the interchange, transmission, and delivery of traffic on the respective railways, as well as for the construction, use, management, and maintenance of the stations, subways, lifts, etc., of the company.

Baker-street and Waterloo.

There are no less than three new railways projected from and to Waterloo, one of which is an underground railway to be worked by electricity, commencing at the western end of New-street, Upper Baker-street, in the vicinity of Dorset-square, running thence by the southern end of Langham-place at its junction with Regent-street, the Quadrant in Regent-street, opposite the County Fire Office, to James-street, Lambeth, about 90 yards from its junction with Lower-marsh. The first directors of the new company would be Colonel the Hon. Henry Walter Campbell, Major-General Charles Taylor Du Plat, Colonel Ambrose Humphrys Bircham, Lieutenant-Colonel Francis Douglas Grey, Mr. Arthur Ralph Ricardo, and one other person to be nominated by the foregoing. The capital would be £1,250,000, consisting of 125,000 £10 shares, with power to subdivide the same into preferred and deferred half shares. It is sought to enter into working agreements with the Metropolitan, South-Eastern, Metropolitan District, Central London, and London and South-Western Railway Companies. Cheap fares, not exceeding 1d. for each journey, would be charged to the labouring classes up to seven o'clock in the morning and after six o'clock in the evening. The Bill also contains clauses saving the rights of the Crown, the Thames Conservancy, under whose direction the works under the Thames would be executed, and the London County Council, and general provisions for the protection of water, gas, hydraulic power, and electric companies; and the time fixed for the completion of the works is five years.

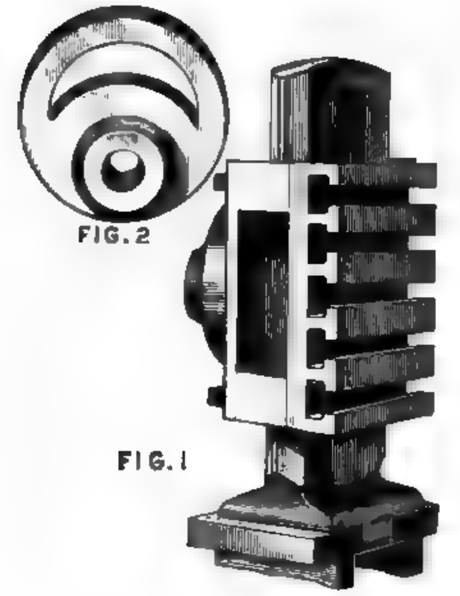
Royal Exchange and Waterloo.

In addition to the intended Waterloo and City Electric Railway, it is also proposed to extend the London and South-Western and London, Brighton, and South Coast Railways to a terminus in the City, for which purpose it is sought to incorporate a new company, consisting, among others, of the Hon. F. S. A. Hanbury-Tracy, Major John Eustace Jameson, Mr. Campbell Praed, and Mr. James Cholmeley Russell, with a capital of £2,700,000, divided into 270,000 £10 shares. Junctions would be formed with the main, Windsor, and other lines of the London and South-Western Company at Waterloo Station, and with the London, Brighton, and South Coast Railway in the parish of St. John, Horseleydown, where it crosses Bermondsey-street by means of a bridge; and the new lines would run by way of Southwark-street to a point in the City close to the junction of Crooked-lane with Arthur-street, crossing the Thames by means of a bridge, in connection with which a free public footway would be constructed. Three years is the time fixed for the compulsory acquirement of land, and five years for the completion of the works. It is also sought to enter into working agreements with the London and South-Western and the London, Brighton, and South Coast Companies, and to pay interest out of capital during construction.

TRADE NOTES—ELECTRICAL AND MECHANICAL.

LATHE ATTACHMENT.

A modified form of shaping attachment is shown in our illustration, designed by Mr. F. M. Rogers, of 21, Finsbury-pavement, E.C., to meet the demand for a tool of this class capable of working on light-built single-geared treadle lathes, such as are used by amateurs and other light metal-workers. The stroke is fixed, and is determined by the throw of the eccentric sheave, shown in Fig. 2, which is screwed direct to the nose of the mandrel, and travels in the grooved path upon the sliding face-plate, thereby imparting a noiseless reciprocating motion to it. The stroke in the size shown, which is that adapted to a 4in. centre lathe, is about 2in., which enables as many as 120 strokes per minute to be taken with ease in soft metal, such as brass or gunmetal.



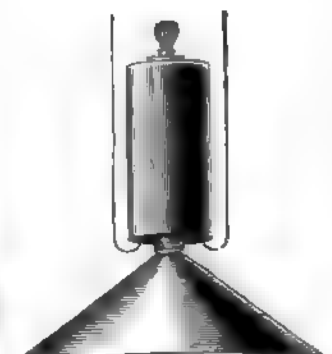
New Form of Lathe Attachment.

The V-shaped packing blocks are of gunmetal, and an adjustment is provided for taking up wear. When fitted with a parallel vice, this little tool will rapidly shape odd pieces of metal which would otherwise have to be filed up. Larger work is bolted to the grooved face-plate. The slide rest is operated by hand or by a self-acting motion. The price, which is moderate, should place it within the reach of every metal-worker.

A NEW FORM OF ELECTRIC MEASURING INSTRUMENT

The accompanying illustration shows an electrostatic instrument recently brought out by Messrs. Swinburne

Swinburne's Electrostatic Instrument.



2,000-Volt Street Lamp with Transformer.

and Co. for experimental work in connection with alternate currents. Instead of quadrants there are two pair of half discs, so that the angle of deflection can be large. The needle consists of two half discs fastened on a metallic arbor. It is held by top and bottom metallic suspensions. One disc is in the upper box and the other in the lower. The boxes are connected, not to ordinary terminals, but to highly-insulated flexibles; as the ordinary terminals are not suitable for high pressures. The instrument can be used as a voltmeter; or it may be connected up to measure power by any of the various methods involving two readings. It can also be connected up as a direct-reading wattmeter. The electromagnet below the boxes acts on a copper drum, and renders the instrument dead-beat. This magnet is excited by a cell. For large readings the torsion head and pointer on top of the instrument are used, but for small readings the mirror is employed. Four of these instruments have been lent to Dr. Fleming to carry out experiments on the measurement of power by various different methods.

A TWO THOUSAND-VOLT STREET LAMP.

Street lighting by alternate currents has for some time past presented considerable difficulties. In most cases transformers are arranged in the houses, and the stations have high-pressure leads only. To run incandescent lamps it is therefore necessary to employ transformers and a system of low-pressure leads. Messrs. Swinburne and Co. have brought out a lamp which contains a small transformer, and is connected direct to the high-pressure system without any low-pressure leads. A 32-c.p. lamp, with protector, is arranged under a large enamelled iron shade, which is secured to the base case of a small transformer. The efficiency of the transformer is high, considering how small it is, being, according to the makers, just under 90 per cent.

COMPANIES' MEETINGS.

ELMORE'S WIRE MANUFACTURING COMPANY, LIMITED.

Directors: J. Jepson Atkinson, Esq.; Edward J. Carson, Esq.; John T. Cooper, Esq.; John Macfarlan, Esq.; Sir John H. Morris, K.C.S.I.; William Elmore, Esq. (managing director). Secretary: Mr. J. Shurmer.

Report of the Directors presented at the first ordinary general meeting of the Company, held at the Cannon-street Hotel, E.C., on Wednesday last.

The Directors have the pleasure to submit their report, and the accompanying statement of the Company's audited accounts, for the period commencing with the incorporation of the Company on March 15, 1890, and ending on October 31, 1891. The period in question has been devoted entirely to the erection of the Company's works upon 13 acres of freehold land purchased from the parent company, and immediately adjoining that company's works. The main building consists of a series of bays, each 400ft. long by 35ft. wide, having a total width of 350ft., under one roof, and covering a space of about 3½ acres. These buildings have been designed with a view to an output of 140 tons per week. There are also offices for the staff and Managing Director complete in every respect, together with convenient store and packing-shed, with sidings from the Midland and Great Northern Railways already connected up therewith. The actual progress made at the works, as reported by the Managing Director, is as follows: Buildings, comprising shop, engine-house, depositing-sheds, boiler-house, dynamo and engine house, and machine shop, for an output of 140 tons per week; chimney shaft, 240ft. high, for 280 tons; railway sidings; overhead cranes throughout, and melting furnaces and flues for 140 tons; boilers, generating engines, dynamos, and electrical switches for 44 tons; fuel economisers, tanks, and tank gearing for 35 tons; engine and dynamo for the electric lighting of the whole works inside and out; shop engine, shafting, and additional gearing; slitting, flattening, straitening, and other machinery for 70 tons a week. From this enumeration it will be seen that the works will make a start with an output of about 35 tons a week. This can be readily increased up to 70 tons a week with little additional expenditure above that already incurred. The Company has also acquired from the parent company, upon a moderate royalty, the sole license outside the requirements of the parent company for the manufacture of copper sheet under a patent taken taken out by the parent company last year, and the Board consider, in view of the large demand for copper sheet, that this license will prove of great value. Since the Company was formed and the buildings commenced, the Directors have learned with satisfaction that the whole of the proposed output can be readily disposed of in the form of ribbon or tape, and planished sheet, at a profit considerably in excess of that estimated from the sale of wire spirals. The Company will therefore neither erect wire-drawing plant on a large scale for the present, nor dispose of its copper spirals to wire-drawers, thus adding to the gross earnings of the Company one manufacturing profit. Mr. Elmore, managing director, reports that early in the

year 1892 the Company will be in a position to commence with an output of 35 tons per week. In regard to the accounts, these are exceedingly simple; inasmuch as no trading account having yet been opened, the only outgoings beyond capital expenditure are those occurring under administration expenses, which, however, have been reduced by one-half, largely in consequence of the satisfactory profit derived from a judicious investment last year in Consols and Bank of England stock. The auditors, Messrs. Deloitte, Dever, Griffith, and Co., offer themselves for re-election, and the Directors recommend a payment to them of 35 guineas for their services.

BALANCE-SHEET, 31ST OCTOBER, 1891.

The first annual ordinary general meeting of the shareholders of Elmore's Wire Manufacturing Company, Limited, was held on Wednesday at the Cannon-street Hotel, under the presidency of Mr. J. Jepson Atkinson.

The **Secretary** (Mr. J. Shurmer) having read the notice convening the meeting,

The **Chairman** said: Gentlemen, the report speaks for itself, and is so exceedingly simple that in addressing you I can have very little to say. What will strike you first is that a company calling itself a wire manufacturing company should propose to you, its shareholders, after you have subscribed your capital, not even to put down plant to draw wire at all. This admits of an easy explanation. Gentlemen connected with the wire-drawing trade, and having large capital invested in drawing plant, approached us some time previous to your last general meeting, and having thoroughly tested the quality of the copper to be produced by us offered to take our entire output at a price which, while satisfying us, did not interfere with their own business of drawing. Your Directors considered that this arrangement was better than entering into competition with the whole trade. This was explained to you at the last general meeting. Since then we have ascertained the fact that by depositing our large copper tubes up to about ¼in. and over, and then cutting them up into a wide spiral of, say, 2in., which can be done very easily indeed, we have a form of copper-ribbon or tape used for electric lighting and transmission of power. While the demand for this copper-tape exceeds our entire output, the price is much in excess of the best price we could obtain for wire spirals such as the wire-drawers would have taken; so that, even before the whole of our works are complete, we shall have a better market for our produce than was contemplated when the prospectus was issued. The electric lighting of a town like Leeds would keep us busy for a length of time, and I am informed that for the electric lighting of London alone over 100,000 tons of this kind of strip will be used. A second very simple invention is likely to form an important source of revenue to us. It was found that by exposing the mandrel to the oxidising action of the atmosphere for a few minutes when a certain thickness of copper was deposited upon it, and then continuing the operation till a similar thickness of copper was deposited, and by a continual repetition of this process, a series of tubes could be formed entirely separate and distinct from one another. One cut down the length of these superimposed tubes gave, when opened out, a number of beautifully-burnished sheets of perfectly even surface and thickness, and equal in every way to those known in the trade as planished sheets. These, of the size furnished by us, cannot be procured at the present time in the market, and consequently they will command a high price. All I have to say in addition to this is that this meeting was put off to the last minute in the hope that I should be able to announce to you that the 35-ton plant was at work. The fog and the Christmas holidays have prevented it, but there is steam in our boilers and very little more to do at the plant, and we hope within three weeks or so to be at work. Our business being a mere repetition of the same process over and over again, and the fact that we have no customers to seek or market to create, make it evident that as soon as ever we get a start our dividend-earning will commence. Some of you have seen the works, and know from what you have seen that a great deal has been done, and the drawing on the table will give those who have not been down an idea of the size of our premises, which, I am told, comprise the largest shed in Yorkshire. To give you an idea of how large a place it is, I may say that I took the managing director of the largest coal company in the North of England to see Mr. Elmore, and as we walked through the buildings he said to me: "I suppose you are going to employ 5,000 hands here." I took him to Mr. Elmore, who, after showing the labour-saving apparatus and the process, was able to tell him that we should not employ 5,000, or 1,000, or even 100 hands, but less than 30. That will give you some idea of the advantages of the process. I have nothing further to say to you, gentlemen; but Mr. Elmore or I will be very glad to answer any questions that may be put to us.

Mr. William Elmore (managing director): The drawings on the table will give you some idea of the magnitude of the building and of the operations carried on. We have one building which will cover something like 3½ acres under one roof—one of the most magnificent buildings in Yorkshire. It is all complete now, and one-third of the plant will certainly be ready for operation in the course of a fortnight; that is equal to 35 tons per week. I may say that we have been impeded very much indeed by the very serious delays of the various contractors who are supplying the manufacturing plant and some of the buildings. The contractors who put the roof on the large building to which I have just referred were something like five months behind with their contract; but everything about the building is now completed, and the plant is capable of turning out 35 tons per week. We have got steam in the boilers now, and the engines are actually working, therefore there is not the slightest doubt that in a fortnight from now we shall be commencing the output I have mentioned. As soon as the first 35-ton plant is in operation we shall commence upon the next portion of 35 tons, and so on until we fill the whole of this building, which is capable of an output of 140 tons per week. There is a demand upon us even at the present moment for far more than we can produce, which is exceedingly satisfactory, and at a very handsome price, which will leave a very large profit. I shall be very glad to answer any questions any gentleman may wish to put.

Mr. Guarracino said Mr. Elmore had stated that with the present plant there would be an output of 35 tons per week. He wished to ask if it was simply a question of multiplying the tanks, etc., to increase the output to 140 tons, or whether they would require further motive power.

Mr. Elmore, in reply, said this was fully explained in the report. Buildings, comprising shop, engine-house, depositing-sheds, boiler-house, dynamo and engine house, and machine shop, had been completed for an output of 140 tons per week. The chimney shaft, which was 240ft. high (a magnificent piece of work), was good for an output of 280 tons. The railway sidings on the Midland and Great Northern Railways had been completed. The overhead cranes had also been completed, as well as the melting furnaces and flues for 140 tons; the boilers, generating engines, dynamos, and electrical switches for 44 tons, and the fuel economisers, tanks, and tank gearing for 35 tons. The engine

and dynamo for the electric lighting of the whole works, inside and out, had likewise been completed, and also the shop engine, shafting, and additional gearing and slitting, flattening, straightening, and other machinery for 70 tons a week. Therefore, with very little additional expense they would have an output of 70 tons per week, but they intended to commence with 35 tons.

The **Chairman** then moved: "That the Directors' report and statement of accounts for the period ending October 31 last be passed and adopted."

Mr. Edward J. Carson seconded the resolution, which was put and carried unanimously.

Mr. Scrutton proposed the re-election of Messrs. Deloitte, Dever, Griffiths, and Co., as auditors for the ensuing year.

Mr. White seconded the motion, which was agreed to.

Mr. Blumer moved: "That the best thanks of the meeting be given to the Chairman for presiding on this occasion, and also to the Directors and officers for their efficient management of the affairs of the Company."

This was seconded by **Mr. White**, and passed with acclamation.

Mr. Guarracino said he did not think the shareholders should separate without according a special vote of thanks to Mr. William Elmore.

Mr. John T. Cooper seconded the resolution, which was adopted.

Mr. Elmore, in acknowledging the compliment, expressed the hope that no effort on his part would be wanting to make the business a thorough success, as he intended it should be.

The proceedings then terminated.

ELMORE'S PATENT COPPER DEPOSITING COMPANY, LIMITED.

Directors: J. Jepson Atkinson, Esq.; Edward J. Carson, Esq.; John T. Cooper, Esq.; G. C. V. Holmes, Esq.; John Macfarlan, Esq.; Sir John H. Morris, K.C.S.I; Frederick L. Rawson, Esq., M.I.E.E.; William Elmore, Esq. (managing director). Secretary: Mr. J. Shurmer.

Report of the Directors presented to the second ordinary general meeting of the Company, held at the Cannon-street Hotel on Wednesday last.

Your Directors have pleasure in submitting to the shareholders their report, and in congratulating them on the satisfactory technical and commercial prospects of the Company. They also submit the accompanying statement of the accounts for the year ending June 30th, 1891, which shows a credit balance at the end of the preceding year of £77,825. 1s. 4d, from which two dividends of 10s. each, making £1 on each £2 share, were paid. It will be seen that the accounts show credit balances on the 30th June last of £14,261. 17s. 10d., made up of £5,000 royalties on copper sheets received in advance, £8,558. 7s. premiums and profit on land, and balance of profit and loss of £703. 10s. 10d., a satisfactory result considering that the Company had only been able to manufacture small quantities of articles at the date of the making up of the accounts—work on a large commercial scale not having been then commenced. The Directors have much satisfaction in announcing the successful completion of the 20-ton plant, and thus the programme of work set forth in the prospectus has been carried out. The cost of manufacture has also now been found to be only about ½d. per pound weight of finished goods (see report below)—that is to say, about one-half the cost that the Directors estimated in the prospectus—whilst the statements as to the technical features of the process have been entirely proved. The Directors are the more gratified in being able to refer to these results, as, though the application of the essential part of the Messrs. Elmore's invention has remained unchanged, various difficulties connected with the mechanical details of the process, inseparable from the commercial development of all important inventions, were encountered. These caused some considerable delay. The Managing Director reports that all these difficulties have now not only been successfully overcome, but that they have led to the taking out of additional patents of great value, which will have the important practical effect of prolonging the monopoly of the invention. Foremost amongst these may be mentioned the patent for the manufacture of sheet copper, the license to work which on a royalty, which will prove a valuable source of income to this Company, has been granted to Elmore's Wire Manufacturing Company. The Directors desire specially to draw the attention of the shareholders to the purchase of the Haigh Park Estate, Leeds, consisting of 127 acres of freehold land, on a portion of which site the Company's works have been erected. The purchase of this property was rendered advisable by the impossibility of acquiring portions of it required for the purposes of the Company and its future extensions, except at the price of £2,000 per acre, whereas the price actually paid for the whole estate was only £534 per acre, including all expenses. The land is within half a mile of the borough of Leeds, connected by sidings with the Midland and Great Northern Railways, and has a wharf on the Aire and Calder Canal, which latter bounds the estate for three-quarters of a mile. It has an extensive frontage to the Pontefract high road, and is in close proximity to cheap coal supplies. The new line of the South Leeds Junction Railway, for which a Bill has been lodged in Parliament, is planned to run through the estate. These advantages and improvements have resulted in what the Directors foresaw—viz., a great increase in the value of the land, which must make the purchase a valuable acquisition for the Company. Negotiations have already taken place for the sale of portions at a considerably higher price than that paid. A plot of 13 acres has been disposed of at £1,000 per acre to Elmore's Wire Company, and this price, whilst yielding an excellent profit to your Company, is nevertheless 50 per cent. below the price demanded for this plot by the former owner, and the Directors are advised that they will be enabled to dispose of the whole of the land not required for the purposes of the Company at a similar profit. The completion of the 20-ton plant was lately marked by an invitation to the larger shareholders to see it at work, and over 100, from various parts of the country, availed themselves of this invitation, and they expressed the greatest satisfaction at what they saw. The Messrs. Elmore have made a joint report to the Board as to the earning powers of the works. This report is of a most important character and is enclosed herewith. By this report it will be seen that the profits of the works as now completed are put at over £45,000 per annum, being 30 per cent. upon the present capital of the Company, whilst when the time comes for doubling the output to 40 tons per week the profits will be increased to over £95,000 per annum, equal to nearly 50 per cent. upon the increased capital that will then be required. These returns, extraordinary as they may seem, Mr. Elmore fully believes will be exceeded by actual results; and considering that the report takes no account of important sources of profit, such as sales of licenses, recovery of precious metals, and special kinds of work, the Directors see no reason to doubt the conc usions therein contained. From the numerous testimonials from important firms, copies of some of which have already been despatched to the shareholders, it has been shown that the goods supplied to customers have given complete satisfaction, and of this the numerous repeat orders, and the offers of a very large additional business at remunerative prices, are a still better and more practical proof. The Directors desire, in conclusion, to record their belief that now that the Company may be considered to have entered upon its legitimate manufacturing business on a commercial scale, the shareholders will find that in the Elmore invention they possess a process that will be a continued source of profit, increasing from year to year, as the quality of the goods produced becomes more and more known. The Directors who retire are Sir John Morris, Mr. Atkinson, and Mr. Carson; the former, owing to ill-health, does not seek re-election; the latter two are eligible and offer themselves for re-election. The auditors, Messrs. Price, Waterhouse, and Co., also retire and offer themselves for re-election.

Since the Directors' report was made out, the result has been received from Leeds of an important competitive trial that has just taken place of an Elmore tube 9in. in diameter and ⅛in. thick against the best brazed tube obtainable, of similar size, made by the ordinary system. The tests showed that the brazed tube burst in an uneven manner at 448lb. pressure. The Elmore tube stood 1,456lb. pressure, being over three times as strong, and then gave way gradually and evenly. Some idea may be formed of the strength of the Elmore tube when it is mentioned that the testing machinery had to be specially prepared, owing to the enormous resisting power of the Elmore tubes.

Report of Managing Director.

To the Directors, Elmore's Patent Copper Depositing Company, Limited.

Pontefract-road, Leeds, Nov. 30th, 1891.

Gentlemen,—As requested, I beg to hand you my estimate of the approximate annual profits to be earned by the 20-ton per week plant, now complete and in operation at the above works, as follows:

Proceeds of 20 tons of copper tubes and other articles, per week, which, per annum (of 50 weeks) is 1,000 tons, equal to 2,240,000 pounds weight, at 1s. per pound ...		£112,000
(1s. 1¾d. per pound weight of copper being the average selling price calculated upon the total of the orders now on the Company's books being executed).		
It is important to note that for every 1d. per pound over 1s. added to the selling price of tubes manufactured by this Company, on a basis of 20 tons per week, over £9,000 per annum will be added to the profits.		
Less cost of production.		
Deduct cost of 1,081 tons rough copper bars, at £50 per ton (market price of Chili bar to-day is £44. 10s.)		54,050
		£57,950
*Coal consumed, 80 tons per week, say 4,000 tons for 50 weeks at 10s. per ton	£2,000	
*Labour £40 per week is per annum of 50 weeks...	2,000	
*Oil, chemicals, and sundries, say £10 per week, is per annum of 50 weeks	500	
*Contingencies, at £10 per week	500	
		5,000
		52,950
Allow for depreciation of plant		2,500
Net profit......		£50,450

*Equal to about ½d. per pound weight for cost of manufacture.

Upon the basis of actual cost at these works, and experience gained on the practical scale to date, I have added to every item from 25 per cent. to 50 per cent. for the purpose of meeting any contingency and being perfectly safe. You will be pleased to note that the cost of manufacture is about ½d. per pound, my original estimate being 1d. per pound. I have made a deduction for wear and depreciation at the rate of 50 per cent. of the total working expenses. Without taking credit for gold and silver recovered from the raw copper, or for the large extra profit to be derived from special kinds of work which the Company's process enables it to take at from 2s. 6d. to 5s. per pound (superseding hand labour at a much greater cost), the net profit equals over 33 per cent. on

£150,000, the issued capital of the Company. Owing to the high quality of the Company's manufactures, and the demand for them indicated by the largely-increasing number of applications for quotations and offers of work, it will be necessary to increase the existing plant, to double the present plant of 20 tons per week and make it equal to 40 tons per week.

The profits will then be, on the above basis, for 20-ton per week plant ...	£50,450
Add for double the production	50,450
	£100,900

There will be required for this extra production £20,000 for plant and £30,000 for working capital; this will make the total capital issued £200,000, on which, on the above basis of profit, the return would be over 50 per cent. per annum. Moreover, there is no reason for taking 40 tons per week as the limit of production. For instance, the French Elmore Company's works, which are nearly completed, are upon a scale of production of 80 to 100 tons per week, and the general manager, M. Secretan, writes that already he sees that the demand will enable the Company to double or even treble the plant within a short period. From the above facts it will be seen that in the Elmore invention the Company possesses a property not paralleled in the whole range of industrial investments, and now that the delay in getting the 20-ton per week plant at work—delay incidental to all new discoveries—has been overcome, the extraordinary earning power of the Company will be appreciated.—I am, Gentlemen, yours respectfully, William Elmore, Managing Director.

P.S.—I have not included in the above estimates the cost of the London and Leeds office expenses, salaries, and Directors' fees, amounting in all to, say, £5,000 per annum, although up to the present time these expenses have only slightly exceeded one-half that sum.

The second annual ordinary general meeting of Elmore's Patent Copper Depositing Company, Limited, took place on Wednesday at the Cannon-street Hotel, Mr. J. Jepson Atkinson presiding.

The **Secretary** (Mr. J. Shurmer) having read the notice calling the meeting,

The **Chairman** said: Gentlemen, there is an old saying, "Good wine needs no bush," and I think that after the report we have been able to send you you will not think it necessary for me to address you at any great length. You will see by the report that all the preliminary difficulties have been entirely overcome, and that we are now ready to go forward and earn money for you, and pay you handsome dividends. When we double, treble, and even quadruple our present plant, which we shall, in due course, have to do, those dividends will be so increased that I honestly believe you will have a chance of getting returns of cent. per cent. upon your investment in the capital of the Company. You will be glad to hear that our difficulty is not to take orders, but to know what orders to refuse out of the great number on offer. As you know, there is a French Elmore Company, formed to work the process in France, and last week I had the honour of being invited to see their works. These works are now in operation, and though designed for an output of 90 tons a week, already their manager reports that he can sell double their proposed output. From these remarks, and the figures which Mr. Elmore will give you, you will see there is not the slightest question about our getting a sufficiency of orders. I have no dividend to declare, but I can state to you, gentlemen, that we are to-day actually earning a considerable one—there is £500 profit in our tanks for this week—and I myself expect that before very long we shall be able to send each of you a nice little cheque as the result of what we are earning. I should like to say a few words about our investment in land, referred to in the report. As you are aware, we are not a land company, and in the ordinary course we should only have bought sufficient land for our own immediate requirements; but being myself an adjacent landowner, and knowing well its value in the neighbourhood of the rising town of Leeds, and finding that we should have to pay something like £2,000 an acre for any extension of our works, and then be exposed later on, if we wished to further increase them, to still larger demands, I strongly urged the Board to make the purchase of the whole estate at Haigh Park. This the Company did not see its way to do at the time, and Mr. William Elmore very pluckily stepped in and bought the property. Later on, when the land had increased in value, and we saw the bargain that Mr. Elmore had, we readily accepted his generous offer to let the Company take over the purchase at the original price. Since that time, as we have mentioned, the value of the land has greatly increased, and I will read you a letter from a gentleman who is acknowledged in Leeds to be the greatest authority on the value of land in that neighbourhood. He writes as follows:

"Aire and Calder Navigation, Leeds, December 26, 1891.

"My dear Atkinson,—You ask me my views in regard to the Haigh Park Estate, lately belonging to Lord Stourton, and now acquired by a company with which I believe you are connected. It is a valuable property, and in the near future must become exceedingly so, as any considerable extension in the manufacturing industries of Leeds must necessarily be in that direction, for there is no land so suitable or now available. I do not know whether you are aware of the fact that the proposed South Leeds Junction Railway of the coming session passes through the estate on its

western side. This, if passed by Parliament, will enhance the value of the estate, although it is already exceptionally situated by having the Aire and Calder Navigation, with its easy connection, on one side, and a junction with the Midland Railway on the south side.

"Altogether, I think the Company have done well to acquire the estate, and especially if they can afford to wait a while before realising.—Yours sincerely, W. H. BARTHOLOMEW."

In addition to this and the other advantages set out in the report, the Midland Railway Company have not only agreed to spend a considerable sum in improving the means of communication with the estate, but have also arranged, later on, to build a passenger station contiguous to our property. In justice to Mr. Elmore I must say that he has worked like a Trojan, and, even if he has been slow in getting our Company to its present prosperous position, he has nevertheless given one of the greatest possible proofs of his zeal for the Company, and his interest therein, by giving up his purchase precisely on the same terms as he had procured it. If he had been a stranger, there would have been nothing wrong in his asking £25,000 profit on the price, and then we should have had a bargain; in fact, if at the end of a year or two the Company do not find that they have made a splendid bargain, I shall be very glad to take it off their hands. I think, therefore, that our thanks are very much due to Mr. Elmore for the excellent position he has put us into in that respect, and I have no doubt that, before we part, you will favour him with a vote of thanks instead of a cheque for the profit he might otherwise have made. Three members of the Board retire. Sir John Morris is not allowed by his physician to offer himself for re-election, but possibly he may be able to join us again later on. With regard to the other two members, Mr. Carson and myself, I may say that Mr. Carson, from his knowledge as a director of the Cape Copper Company, of which he was originally the manager, has been of great assistance, and is one of the four largest holders of our shares. I myself have every confidence in the great value of this invention, and have had ever since it was only an idea in the mind of the inventor. I hold over 8,000 shares in the Company, and have upwards of £40,000 in the various Elmore companies, and have never sold a single share, even when they were at £8 each, which figure I believe they will soon be at again. On the contrary, I have been steadily increasing my holding. In fact, I may say the Directors of your Company are by far the largest holders in the Company, holding, I believe, nearly a third of the issued capital. The Chairman then read a report from Mr. Elmore, confirmatory of his statements, to the following effect:

"I beg to confirm my report of November 30 last, and the gratifying results I was then able to foreshadow, and to state that our experience since more than bears out my figures. Since my previous report of June 1, 1891, the new copper mandrel has proved to be all that I then claimed for it, and it even exceeds my expectations, simplifying the process immensely. I send you the two tubes recently tested by an independent expert, one made by our electro-burnishing process and the other one a brazed tube of the best ordinary make. The result of the trial you already know of—viz., that the Elmore tube turned out to be not only more than three times as strong as the best brazed tube, but of such high uniform quality that, although the testing machine had to be specially made, the machinery actually gave way two or three times in the course of the tests, and had to be strengthened to meet the great resisting power of the Elmore tube. From this it will be seen that the Company will practically have the monopoly of steam-pipes of large diameter, and that marine engineers will at once abandon the use of brazed copper pipes, which have given them so much trouble of late by bursting under the high steam pressures used in the triple and quadruple expansion engines, some 50 or 60 lives having been lost during the present year from this cause; and I may state that we have already received some important communications and assurances to this end. The difference in the two kinds of tubes cannot be better expressed than in the words of the eminent engineer who made the test, as follows: 'I beg to inform you that I have to-day witnessed the bursting of two experimental copper pipes, one made by your electro-burnishing process, the other an ordinary brazed tube, made by a first-class coppersmith in Leeds. The first pipe is 5ft. 6in. long, 9¼in. in diameter inside, and ¼in. thick. The pressure was applied to the inside of this pipe by means of a three-throw hydraulic pump driven from the shaft in the shop. Up to a pressure of 1,000lb. per square inch the pipe showed no signs of distress. At a pressure of 1,176lb. to the square inch the pipe commenced to expand in the middle uniformly, until this part of it became ⅜in. larger in diameter than the other part, and water commenced to pass from four separate points almost opposite to each other, showing that the metal was stretching uniformly, and that the pipe was almost on the point of bursting. The pressure was again increased until 1,456lb. to the square inch was reached, when the pipe stretched at this part from 9¾in. outside diameter to 11in., and at this pressure it burst, opening out in the centre of the pipe for a distance of about 10in., the fracture being 1¼in. wide. The pipe was afterwards measured, and it was found that although at the moment of fracture its diameter was 11in., and the metal had stretched uniformly to that extent, still when the pressure was released the pipe returned to a diameter of 10⅜in. The next pipe—that is, the brazed one—was 9in. diameter, also 5ft. 6in. in length and ¼in. thick. At a pressure of 120lb. to the square inch, one end of the pipe swelled to the extent of ⅛in. in diameter for a distance of about 12in. from the flange, and as the pressure was increased to 300lb. the opposite ends swelled in like manner, which clearly proves that in heating the copper to flange it at each end its ultimate strength had been greatly reduced. The pressure was again increased to 448lb. to the square inch, when the pipe burst at one end, about 12in from the flange, through the brazed joint, thus demonstrating that the electro-burnished pipe, although ¼in. larger in diameter than the brazed pipe, was 3¼ times stronger, and further demonstrates that owing to the great ductile properties possessed by the electro-burnished copper, which admits of its being flanged without being heated, enables pipes of this description to be constructed of a uniform strength throughout.' It is important to notice that the Elmore tube was flanged (in the ordinary way by an ordinary workman) without annealing, thus preserving to the metal its whole original strength, and avoiding all possible chance of deterioration of the metal by overheating owing to want of skill or carelessness on the part of the workmen. As showing the rapidity of the growth of our trade, and the favour in which our goods are held by those who have tried them, I would state that we have already, during the last two months, added no less than 130 customers to our list, comprising some of the best firms in the country. We have executed 342 orders, and have to-day more orders offered than we can possibly execute. Further, one large buyer has given 16 repeat orders; one has repeated orders 14 times; two have repeated orders 12 times each; three have repeated orders 11 times each; two have repeated orders nine times each; five have repeated orders seven times each; three have repeated orders five times each; seven have repeated orders four times each; 10 have repeated orders three times each, and an aggregate of 224 repeat orders have been received from a number of our customers, representing about 40 per cent. of the total names upon our books. We have on hand orders and offers of orders at prices above those that I estimated in my last report, which will far more than fill our capacity for a long time to come. In addition, since the 20-ton plant was started we have received specifications and sent out quotations in reply to enquiries for 1,561,669lb., or over 700 tons, of copper tubes for various purposes, besides a large amount of copper to be deposited upon rams and other expensive articles, from which to draw our orders and keep our tanks constantly employed. I further have pleasure to officially inform you that another stage in the realisation of the promises that I have made has been reached, which, with the exception of the delay in actual completion, have been more than borne out in every case. This important step is the satisfactory production of a copper cartridge case, the value of which may be gathered from the fact that it means the successful application of the Elmore process to pans for brewers and distillers, and other articles not of tubular form but having a bottom. From the samples I send it will be seen that not only is the copper cylinder closed at one end, but the thickness of the copper can be regulated at will, to be thick at one part and thin at another, as desired, whilst the quality is kept at the same high standard as our tubes. If it is possible, as has been proved, to produce such an article by the Elmore process, it can at once be seen by any expert that it is far easier to produce than an ordinary pan, and in my estimate of profits, which I made out on November 30 last, no allowance whatsoever was made for such special articles, the extra profit upon which will all be in addition to what was there set out; and the fact that I am at present negotiating for making arrangements for the granting of a license for the manufacture of a minimum of 10 tons of these cases per week, on a royalty that will be most remunerative to this Company, will show that I have erred on the safe side in making out my estimate of profit. In this report of to-day I have confined myself to what has actually been done and proved, and I consider it unnecessary to refer to the fact that our process is equally applicable to the deposition of other metals, and the manufacture of heavy ordnance, of a quality hitherto unknown, and I think you will find, as in the past, that every statement ever made by me as to the various applications of the process will be as fully borne out as those regarding the turn-out of copper tubes and such-like articles; this I have been able to prove to you to-day."

The **Chairman** then moved the adoption of the report and accounts.

General Fyfe seconded the resolution, which was agreed to.

Mr. Pilcher said he had given the Company an order for two steam-pipes for marine purposes to stand 165lb., but they were laminated throughout. He would like to know the reason of this; also how the cost would compare with that of the ordinary pipes for marine purposes.

Mr. Elmore said that at the commencement they unfortunately started with a defective engine, which, although constructed by one of the best engineering firms in the world, had broken down continually. The breaking down of the engine caused the operations to cease in the tanks, the process being essentially a continuous one. That was the cause of the lamination, and when he became the managing director at the works he found that some of the tubes had been sent out which were made during that early time, amounting to six in all. If Mr. Pilcher would favour the Company with another order he believed they would be able to satisfy him. An official test was about to be made in conformity with the Board of Trade specifications, which he believed would be in every way satisfactory.

Mr. Pilcher: Will you guarantee them, and put in the ordinary tubes if yours are a failure?

Mr. Elmore: Yes; with pleasure.

Mr. Pilcher: Then I will undertake to give you an order.

Mr. Rawson: I will send you a cheque for £500 if the tube proves in any way defective.

Messrs. Atkinson and Carson were re-elected directors, and Messrs. Price, Waterhouse, and Co. were re-appointed auditors.

Dr. Cantrell next moved a vote of thanks to Mr. Elmore and the Company's staff.

Mr. Guarricino seconded the resolution, which was agreed to.

The meeting closed with a vote of thanks to the Chairman and Directors.

NEW COMPANIES REGISTERED.

California Gas, Water, and Electric Lighting Company Syndicate, Limited.—This Company has been registered with a capital of £2,000, in £1 shares, to purchase or otherwise acquire, work, manage, and turn to account gas works, electric light plants and water works in the U.S.A., Canada, or the British Colonies. Registered office, 20, Bucklersbury, E.C.

Chloride Electrical Storage Syndicate, Limited.—Formed, with a capital of £262,500, to acquire certain patents and property, to carry on business as ironmasters, copper smelters, steelmakers, ironfounders, engineers, boilermakers, metallurgists, electricians, electrical contractors, electrical and mechanical engineers, and suppliers of electricity, and to carry on the business of an electric lighting company. The subscribers are: Messrs. J. E. Yeates, 9, Solent-crescent, West Hampstead; W. J. Torney, 24, Granard-road, Wandsworth Common; S. S. P. Cooke, 53, Chadwick-road, Peckham; R. J. Rumball, 46, Ruvigny-gardens, Putney; F. B. Liley, 58, Sandmere-road, Clapham; S. S. Ludlow, 34, Werter-road, Putney; and E. J. Newball, 57, Cowley-road, North Brixton.

Liverpool Metal and Hardware Company, Limited.—Registered by J. and R. Gole, 4, Lime-street, E.C., with a capital of £12,000 in £10 shares. Object: to acquire the undertaking of P. C. McIntyre and Co., Limited (of Hanover-street, Liverpool), in accordance with an agreement made between J. Huntington of the one part and this Company of the other part, and generally to carry on business as general metal and hardware merchants, mechanical and electrical engineers, etc., in all their respective branches. There shall not be less than three nor more than eight Directors. The first are J. Baker, J. Huntington, C. Coward, W. Heaton, J. G. Russell, P. B. Coward, and J. W. Baker. Qualification, £500. Remuneration, £150, divisible.

BUSINESS NOTES.

Fog Signals.—We understand that a syndicate is being formed for £25,000 to purchase half of the patents of the fog-signal system we described last year, and negotiations are proceeding.

Commercial Cable Company.—The numbers are published of 1,200 mortgage debentures of £100 each of the Commercial Cable Company, which have been drawn for payment at par on January 15 next.

City and South London Railway.—The receipts for the week ending December 27, 1891, were £871, as against £785 for the corresponding week in 1890, showing an increase of £86. The aggregate receipts for half-year to date were £19,221.

"**Electrical Plant.**"—Mr. E. R. Dolby retires from the editorship of the monthly journal *Electrical Plant*, after editing the special "central station" number and the ordinary January issue, 1892, and will devote his entire attention to his consulting practice at 8, Princes-street, Westminster. The proprietors of *Electrical Plant* have turned the business into a limited company, and owing to increase in size, the work will now require the whole time and attention of an editor. Mr. H. Cuthbert Hall, who has acted as assistant for the special number, will undertake the work, the offices of the journal being at 52, Queen Victoria-street, E.C.

COMPANIES' STOCK AND SHARE LIST.

PROF. W. CROOKES, PRESIDENT, SPEAKING AT THE INSTITUTION DINNER.

ONE OF THE FOUNDERS.

GENERAL WEBBER, C.B.

PAST-PRESIDENT.

Mr. W. H. PREECE, F.R.S.

PRESIDENT, 1892.

PROF. W. E. AYRTON, F.R.S.

THE SECRETARY.

F. H. WEBB.

VICE-PRESIDENT.

SIR DAVID SALOMONS.

NOTES.

Islington.—We understand that Colonel Gouraud is organising a company, with a large capital, for furnishing the electric light to the Islington district.

South American Cables.—The Western and Brazilian Telegraph Company, Limited, notify that direct communication by their cables with Monte Video and Buenos Ayres is now restored.

Patent Office Library.—It is hoped that a technical library will be established on the ground floor of the new Patent Office extensions. The alteration, if carried out, will be greatly appreciated.

Electric Fireworks at Chicago.—The Committee on Ceremonies has appropriated 25,000dols. for electric fireworks at the time of the dedication of the exposition buildings in October, 1892.

Mining Plant.—At the meeting of the Chesterfield and Midland Counties' Institution of Engineers on Saturday, Mr. M. Deacon will read a paper entitled "Notes on a Small Electric Pumping Plant."

Fatal Accident in Italy.—A fatal electric lighting accident occurred on Saturday night at the Theatre Mangano at Palermo. One of the men inadvertently took hold of both connecting wires, and fell dead.

Correction of Address. — Messrs. Vaughan and Brown inform us that their address is 16, Kirby-street, E.C., and not Purdey-street, Hatton-garden, as given in the list of exhibitors at the Crystal Palace.

Presidential Address.—The first meeting of the Institution of Electrical Engineers for the coming year will be held on the 14th inst., when the president, Prof. W. E. Ayrton, will deliver his inaugural address.

Shrewsbury.—Mr. Richard Hanway has written a letter to the *Shrewsbury Chronicle* giving a considerable amount of useful information to intending users of this illuminant, in a clear and straightforward style. The interest in the neighbourhood on this subject seems to be keen.

Morse Wires.—One of the exhibits that the Baltimore and Ohio road expects to show in the Electricity Building is a model of the first telegraph wire strung along that line by Morse. The line was nine miles long and extended from Baltimore to Relay Station. The line was laid in a lead pipe.

Salford.—At the Salford Town Council on Wednesday, in answer to a question by Alderman Dickins, the deputy-chairman of the Gas Committee (Mr. Philips) said that a sub-committee had been appointed to consider the subject of electric lighting in the borough, and their report would be submitted in due time to the Council.

French Journal.—*L'Industrie Electrique*, the new French technical journal, is to be issued with the beginning of the year. The editor, as we have already stated, is M. E. Hospitalier, who we were glad to welcome recently on a visit to England with reference to the recent progress in electric underground railways and other matters.

Appointment.—Mr. Alfred Hay has been appointed demonstrator of electrical engineering at the University College, Nottingham. Mr. Hay served his apprenticeship at the Faraday Electrical Works, Govan, and studied electrical engineering at the Glasgow Technical College, under Prof. Jamieson, thereafter taking the Edinburgh University B.Sc. degree.

Electric Heating.—The Maloja Kursaal on the Engadine is to be heated electrically during the winter by power derived from the Mera river in Aseima. There is no doubt that considerable use will be made of electric heaters in those cases where natural power is abundant, and it is probable that this department of electrical engineering will become exceedingly important in such cases.

Overhead Trolleys. — The Common Council of Brooklyn, U.S., has given permission to the tramway companies to change their motive power to the electric overhead trolley system. This decision, which is expected to be at once confirmed by the State Railroad Commissioners, will mean the expenditure of £2,400,000 during the next two years on the Brooklyn tramways.

Electric Fire Alarm.—A development of the electric fire-alarm system has been put into practice at Boston, U.S.A., by the application of the call system to a cab-driver's stand. On an alarm being given, the cabman wakes, the horse is harnessed, and word is given of the address of the owner of the threatened premises, who when fetched is usually able to afford helpful information.

Chicago Exhibition.—From an advertisement in another column it will be seen that applications for space in the British section may now be addressed to the secretary of the Royal Commission for the Chicago Exhibition, at the offices of the Society of Arts, John-street, Adelphi, W.C., where prospectuses and forms of application can be obtained. The date previous to which applications must be received is February 29 next.

St. Elmo's Fire.—A correspondent of the *Glasgow Herald* state that on the 28th ult., when he and another gentleman were walking in a driving shower of hail, the tips of their umbrellas had a glow of fire similar to that from a frictional machine. Was it, he enquires, due to the state of the atmosphere, the charge given by the hailstones, or the friction of these latter on the silk? It is, at least, an interesting occurrence to record.

Electric Conduits.—The Johnstone patents for the protection and preservation of electric wires underground, says the *Financial News*, have been acquired by an English syndicate, and will be brought before the public shortly. Mr. Johnstone hails from Philadelphia, and at a Clover Club dinner was once christened "Lightning," in contradistinction to Mr. Johnstone, the lawyer, whose deep bass voice acquired for him the sobriquet of "Thunder."

Electricity and Life.—Prof. M'Kendrick, F.R.S., of the University of Glasgow, has been giving an exceedingly interesting set of Christmas lectures at the Royal Institution upon "Life and Motion," dealing principally upon the part played by electricity upon muscular activity. Prof. M'Kendrick's lectures cannot fail to bring home to many minds interested in physiology and biology the great share that electrical action has in the still unsettled problems of life, muscle, and nervous energy.

Works on the Telephone.—Messrs. Whittaker and Co. have made arrangements with the editor of *El Telegrafista Espanol* for the translation into Spanish of Mr. Preece's work upon "The Telephone." The book already has been translated into both French and German. The same firm will publish shortly, in a cheap form, Mr. A. R. Bennett's papers on the "Telephoning of Great Cities" and the "Electrical Parcel Exchange System," which attracted considerable attention at last year's British Association meeting.

Marine Lake at Southend.—In order that visitors to Southend may be able to indulge in boating and other amusements on the water at all hours of the day without having to go a distance of a mile or more along the pier, a company is asking for incorporation with the object of constructing, in conjunction with the Local Board, a

marine lake, forty acres in extent, on which miniature steamboats, yachts, and pleasure boats would be let on hire. Here is a chance for the General Electric Traction Company and their launches.

Preston.—The staff of the National Electric Supply Company, Limited, Preston, and a few friends, held their first annual supper on New Year's eve, to celebrate one year's work of the electric lighting of Preston. The chair was taken by F. F. Bennett, Esq., M.I.E.E., supported by the committee—viz., S. F. Emerson, T. Cross, S. Powell, and C. Gillin. Toasts were proposed to the "Queen," the "Directors," the "Managers," and the "Guests"; after which music and singing were indulged in to an early hour, and altogether a very enjoyable time was spent.

Electric Ploughing.—Mr. A. A. Denton, of the United States Department of Agriculture, is seriously advocating the use of electric motors instead of horses in the great plains of the West for ploughing, sowing, reaping, harrowing, and thrashing. The problem involves the backward and forward movement of a machine in a straight line of half a mile, passing to and fro until the field is covered. "We shall wonder," says Mr. Denton, "a few years hence how man produced food by means of the whip. There is [illegible]nt demand in agriculture for electrical engineering."

Shiplighting at Devonport.—Arrangements have just been completed at Devonport for lighting the ships under construction by electricity. The system has been in use for some years at Portsmouth, but has never previously been introduced at Devonport, whilst at Chatham it was tried and abandoned, owing, it is stated, to the expense. On board the "Edgar," at Devonport, a portable dynamo, engine, and boiler has been placed, which is capable of lighting 360 lamps. The cost of such lighting is estimated at £2 a day. Three vessels on the building slips have also been similarly illuminated, with good results.

An Electric Lamp Thief.—A thief who has for a long time, in all probability, been stealing incandescent electric lamps at the Paris theatres, has just been arrested by a clever device of the management of the Porte St. Martin. As it was found that a great many lamps had disappeared at the house the electrical engineer so arranged the fittings that immediately a lamp was removed the electric current sounded an alarm. The man was thus caught as he was making away with a lamp in his pocket, and, as he refuses his name and address to the police, it is believed that he has a large store somewhere of the stolen articles.

St. Pancras Lighting.—The St. Pancras Vestry have deposited a Bill, which will be introduced into Parliament next session, under which powers are sought to raise £60,000 for the electric lighting of the whole of the parish, in addition to any sum that may be required for paying the costs of obtaining this Act. The period for the redemption of the loan is fixed at 42 years. The Vestry also seek power by this Bill to appropriate for electric lighting purposes the pneumatic tubes laid by the Pneumatic Despatch Company, but now abandoned, in Tottenham Court-road, Euston-road, Hampstead-road, and Drummond-street.

Limerick.—Indications seem to show that electric lighting is progressing in Ireland, if not more rapidly than in England, yet with rapid strides. Amongst others, the city of Limerick has now decided to apply at once for a provisional order, the special meeting of the Corporation adopting a resolution to that effect proposed by Mr. Bernal. Mr. Conolly, the law adviser to the Corporation, stated that the cost would be about £200. Mr. Clune said that the cost of gas was greater in Limerick than in any other town of its size, whereat Mr. Conolly stated that when the debt of £4,000 odd was paid, which was being done, the price would be put down.

Pontypool.—A company having for its object the lighting of the town of Pontypool by electricity is being formed, and an influential meeting of tradesmen and others interested will be held at once. As the Local Board cannot obtain the necessary powers for nearly two years, the company will at first be a private one, to be eventually transferred to the Board at the original cost, and the profits made will then be spent on improvements in the town. The directors, it is stated by the *South Wales Daily News*, are in a position to guarantee a dividend of not less than 10 per cent., the project having been most warmly received, and the promises of support already given more than sufficient to ensure this desirable result.

Overhead Wires at Chelmsford.—The Fire Brigade Committee reported to the Chelmsford Town Council at their last meeting with reference to the communication from Messrs. Crompton and Co. as to the cutting of the electric light wires in case of an outbreak of fire in proximity thereto. A representative of Messrs. Crompton and Co., who attended the meeting of the committee, stated that the lighting of the town was divided into four sections, and that in case of fire the light could, if necessary, be cut off in one section only. The committee recommended that Messrs. Crompton and Co. be asked to take such steps as they thought necessary to prevent any danger from the wires in case of fire. The report was adopted.

Teignmouth.—The Teignmouth Local Board finding that the increasing demand for gas is likely to necessitate extensive alterations at their works, are considering the desirability of introducing electric light, and have asked Mr. H. D. Massingham, the well-known electrical engineer, who has had considerable experience of public lighting by electricity, for an estimate of the cost of an installation. The matter was considered at a special meeting on Saturday, Rev. Anson Cartwright presiding, when the Board had a consultation with Mr. Massingham. The estimate was discussed at length, but no definite details of the scheme can yet be given. It is thought fairly certain, however, that electric lighting will be adopted.

Paris Exhibition.—A detailed analysis of the accounts of the great Paris Exhibition has been published, from which it appears there is a balance of £400,000 to the good; £90,000 was received for concessions for cafés and restaurants, and £2,000,000 were received for admissions, or £280,000 more than expected. On the other hand, the expenditure, which had been estimated at £1,860,000, was only £1,600,000. In other words, while the 1889 exhibition left a profit of £400,000, that of 1867 gave one of only £112,000, and that of 1878, organised at the cost of the State, left a deficit of £1,268,000. It should be pointed out, however, that in 1878 there was no subsidy from the State, whereas in 1889 the State contributed £680,000, and in 1867 £240,000.

Portrait of Benjamin Franklin.—Mr. David Murray, 169, West George-street, Glasgow, writing to the *Glasgow Herald*, asks if anyone can tell him of the whereabouts of a repli[illegible] of the celebrated portrait of Benjamin Franklin, painted by the French artist Chamberlin, which is said to be in Scotland. The Hon. Robert C. Winthrop, of Boston, late pr[illegible]ent of the Massachusetts Historical Society, says (Massachusetts Historical Society *Proceedings*, xv., pp. 160-161) that it is in the possession of a member of the William Penn family in Scotland. Who this is, or where the portrait is, he has not been able to ascertain. The information is sought for the memorial volume on the

centennial of George Washington's inauguration, now being completed in New York.

Kendal.—The Town Council of Kendal are exercised upon the question of overhead wires. Councillor Hargreaves, at the last meeting, said he understood that certain parties were supplying customers with electric light, and he wanted to know the rights of the case. The town clerk said that if anyone wished to establish themselves under the Electric Lighting Acts they would have to get the permission of the Board. Later, the application of Mr. Gilkes for permission to erect poles leading from the Canal Iron Works to his house came before the Council. It was mentioned that permission had been asked only after the posts were erected, and to this objection was taken. Councillor Jeffreys stated that there was not the least danger from Mr. Gilkes's wire, and the matter was passed.

Manchester.—It will be remembered that the proposal of the engineers at Manchester, with reference to electric lighting, was that the electric plant should be established on the same site and in the same engine-house as the hydraulic power plant. The Gas Committee, at their last meeting, arrived at a decision electrical engineers will approve, that having regard to future developments and the probabilities of extension of both electric light and hydraulic power, the site at Dickinson-street be allotted entirely to the electric central station, and that in Gloucester-street to hydraulic power. The tenders for boilers and engines have already been advertised for, and with this practical and sensible attitude, we doubt not that Manchester will achieve a successful result from both public and electrical points of view.

Liverpool Overhead Railway. — Among the Bills which have been deposited in Parliament for the coming session is one which proposes to carry out a line of overhead railway similar to that adopted in New York. In previous years Parliament has authorised such a line in connection with the Mersey Dock at Liverpool, which is now in course of construction by the Liverpool Overhead Railway Company, and application is now to be made to extend the time for the execution of the works already authorised, and, in addition, to extend the line both northwards and southwards. The company is to be empowered to work the railways either by electricity or steam, and there is also a provision authorising the Corporation of Liverpool to contribute to the capital of the company for the purpose of carrying out the scheme.

Bombay Docks.—The electric light has now been installed at the Prince's and Victoria Docks, Bombay. Three lights are run up at an average height of about 70ft.; one light for each dock, and a central one between both, erected on a gigantic overtopping mast. It is constructed of iron as far as the crosstree and of timber upwards. The engine-house is not yet finished, but the erection of the lights was considered of so much importance that the light was started before the completion of the premises. The success of the installation is due in a large measure to the indefatigable exertions of Mr. A. M. Taylor, engineer to Messrs. Siemens Brothers, of London, who have supplied the plant. Preliminary experiments had been conducted to the satisfaction of the Dock Committee under the immediate supervision of Mr. Taylor before the final installation was commenced.

Finsbury Special Lectures.—On January 20, 1892, Mr. A. Reckenzaun begins a course of six lectures on "Electric Locomotion," dealing with electric tramways and railways. These will be given on Wednesdays at half-past seven. Through the spring, also on Wednesdays, Mr. Rousseau's practical classes will be held in the new electroplating laboratory, in connection with which Prof. Thompson will give three special lectures on dates to be announced. On February 9 and succeeding Tuesdays, Mr. W. C. Clinton will give a short course on vector methods of calculation in relation to electrical problems, being an introduction to the writings of Mr. Oliver Heaviside; Prof. Perry is continuing his course on the application of the differential and integral calculus, and will conclude by an exposition of Fourier's theorem in relation to alternate currents and the use of the electro-dynamometer in harmonic analysis. Prof. Silvanus Thompson continues his ordinary course of Monday lectures, the topics until Easter being transformers, alternate-current motors and the design of continuous-current dynamos.

City Lighting.—The abominable Christmas weather has led business men in the City to see the advantages likely to accrue to users of the electric light. "It can but be admitted," says the *City Press*, "that while the lighting of the streets is vastly improved, the illumination of private establishments, such as shops, offices, and warehouses, by the electric light will contribute vastly to a general improvement. The wholesale miseries from which the citizens suffered during Christmas week—to say nothing of the damage to property, and increased expense, by reason of the filthy and suffocating fog which enshrouded everything—must have convinced all that the present means of combating the fog-fiend are utterly inadequate, while at the same time the use of gas does not tend to improve matters. It is probable that the contracts held by the City of London Electric Lighting Company may not be actually completed by February, although an honest attempt is being made to do so; but in the event of the work being unfinished a small extension of time would facilitate matters." We are glad to see such a helpful attitude.

Telephonic Facilities. — The National Telephone Company will introduce a Bill into Parliament next session by which they seek to obtain additional facilities for conducting the business of telephonic communication. The Bill, subject to certain provisions as to the consent of road authorities and the repair and reinstatement of roads, gives the company power to place and maintain telephone wires under any public road and to alter or remove the same; to place and maintain a telephone wire over any public road or over any land or any estuary or branch of the sea, and to attach a telephone wire to any land, and to maintain posts on any land, and alter or remove the same, giving compensation to all bodies and persons who sustain damage by reason of their action. In the case of attaching wires to private property, it is provided that where the owner and occupier are not the same person, the consent of the occupier shall be sufficient during the term of his occupation, but no longer. The New Telephone Company, Limited, have also introduced a Bill for the purpose of reincorporating the company and defining its capital, objects, and powers.

Death.—Mr. Frederick R. Leyland, president of the National Telephone Company, died suddenly on Monday night in a train on the underground railway between the Mansion House and Blackfriars Stations. Soon after leaving the former station he was seized with a fainting fit, and Colonel R. Jackson, who was riding with him, called the guard's attention to him at Blackfriars Station. He was at once carried into the waiting-room. Dr. Green was quickly on the scene, but upon examination Mr. Leyland was found to be dead. Mr. Leyland was formerly connected with the steamshipping house of Messrs. Bibby, Son, and Co. Mr. Leyland, in 1873, established the line of steamships connected with his name, which now comprises 23 vessels. He lived for the greater part of the time at his London residence, 49, Prince's-gate, his Liverpool

residence being Woolton Hall. He was an accomplished linguist, a connoisseur in fine arts, and possessed a collection of fine paintings. He was an expert in shipping matters, and besides holding the position of president of the National Telephone Company, was one of the directors of the Edison-Swan Company. His death was very sudden, heart disease being thought the cause of death. His London residence was a most handsome mansion, his dream being to live the life of an old Venetian merchant in London. The walls are adorned with paintings by Millais, Rossetti, Burne-Jones, Watts, and others of the best English artists, besides examples of Bellini, Botticelli, and Raphael. He was 61 years of age and leaves a son and two daughters, one of the latter being married to Mr. Val Prinsep, R.A.

Gas v. Electricity.—There is an interesting interview in the *Daily News* of Monday with Mr. Orwell Phillips, of the gas works at Horseferry-road. Mr. Phillips metaphorically snaps his fingers at electricity, but trembles at the fourpenny petroleum lamp. With regard to electricity he says, what is to a large extent true, that the West-end mansions are not filched from the gas companies, but from the sellers of wax candles. The occupiers of the best houses will not use gas—it is too disagreeable, hot, dusty, evil-smelling a light to suit them. Candles were their resource until electricity came upon the field. An interesting fact, however, comes out with regard to the consumption of gas in Bond-street. Everyone who has visited this street knows that from end to end at least half the shops now use electric light. "Only as an advertisement," says Mr. Phillips—"look at the back shops and you will still find gas." And he has had the curiosity to compare the returns of gas consumption before Sir Coutts Lindsay put up his machines, and with the receipts four years later. He found that at the earlier period the receipts from Bond-street were £7,200, and at the later period £7,800. Perhaps, however, there lurks a mystery in the words "four years." If he examines five or six years later—what then ? Does this represent the year that is past or not ? But, at any rate, the increase, in spite of the substitution of some electric light, is interesting, and bears out what has been noticed in other parts. Will it continue—we shall see ; but it is necessary for gas managers to put a good face on it, and will be still more necessary for them to set about introducing large gas engines for producing electric light. This will be of use, and electrical engineers will then work with them.

Cost of Electric Energy.—The discussion in the *Financial News* upon the "sheer" cost of the production of electrical energy still continues, and promises to lead to interesting and important results. We shall have more to say upon the subject when the correspondence is complete ; meanwhile we will content ourselves in advising practical men to read the correspondence, and, if possible, give their experience in advocating the usefulness of electrical distribution to financial men. Mr. E. F. B. Harston apologises to Mr. Crompton for mixing him up with another company, but at the same time maintains that with any company charging 8d. a unit the bills will be three times that of gas. Mr. John W. Stringfellow, mechanical engineer and specialist, makes an offer to act alone, or in conjunction with others, as stakeholder of, say, £500 for a practical test of gas against electricity of 10 low-power and 10 high-power lamps, the installation to embrace complete plant in itself, and the fixed cost of working to be taken. He suggested the Thames Embankment as the best site for the proposed test. Mr. Albert Gay, manager of the House-to-House Company, objects to the statement that Crompton is a rival of their company, the districts being separate. He asks what is meant by sheer cost, and gives six heads : raw material, wear and tear, wages of men, salaries of officers, rent, etc., and general expenses, of which only the first and third he supposes to be included in "sheer cost." Mr. Harston returns to the charge, and asks, "Cannot the cost be reduced ?" and wished to know whether the companies cannot charge 4d. instead of 8d. a unit. Messrs. Crompton, answering Mr. Gay, admits the first three of the divisions of expenditure as included in "sheer" cost. They reiterate that they are prepared to prove to a committee that if gas and electricity were produced on a sufficient scale—say enough to supply two square miles of London—the cost of electricity would be as low, if not lower, than that of gas.

J. H. Holmes and Co.—Though late in the day, we venture to record the fourth annual dinner of the employés of Messrs. J. H. Holmes and Co., held on Saturday, the 26th ult, at The Crown Hotel, Newcastle-on-Tyne. About 50 persons sat down to dinner. After dinner a most enjoyable programme of music, vocal and instrumental, was listened to, and, in response to the toast, Mr. J. H. Holmes gave a very interesting account of the evolution of the firm of J. H. Holmes and Co. The firm was established in 1883, and made their first dynamo in June, 1885. This, they have recently heard, is still working very well. The first ship lighted on the Tyne was lighted by this firm, as was also the first ship hailing from the Tyne—viz., the "Tynesider." The fame of the Castle dynamo really commenced at the Newcastle Exhibition in 1887, and the same year the firm entered their present premises, which were doubled in less than two years. At the present time over 500 dynamos bearing this name are at work, and the six hundred and twenty-fourth machine is now being built. Mr. Holmes commented upon the good feeling which existed between the firm and its employés, and expressed the wish that this might long continue. Mr. Holmes was frequently applauded during the course of his remarks, and at the conclusion the whole company joined in the customary goodfellowship chorus. The toast to the firm's "Electrical Engineers" was responded to by Mr. Broadbent (the outside manager), who gave a brief summary of the year's work. He remarked that during the year the firm had completed over 90 installations, including ships, collieries, hotels, houses, etc., and had fixed over 11,500 lamps. The total number of dynamos erected on these installations was 95, having an output of 13,605 lamps of 60 watts each, or 816,300 watts. The number of dynamos made up to date during the year was 125, having an output of 2,650,000 watts. The meeting broke up after a very enjoyable evening had been spent.

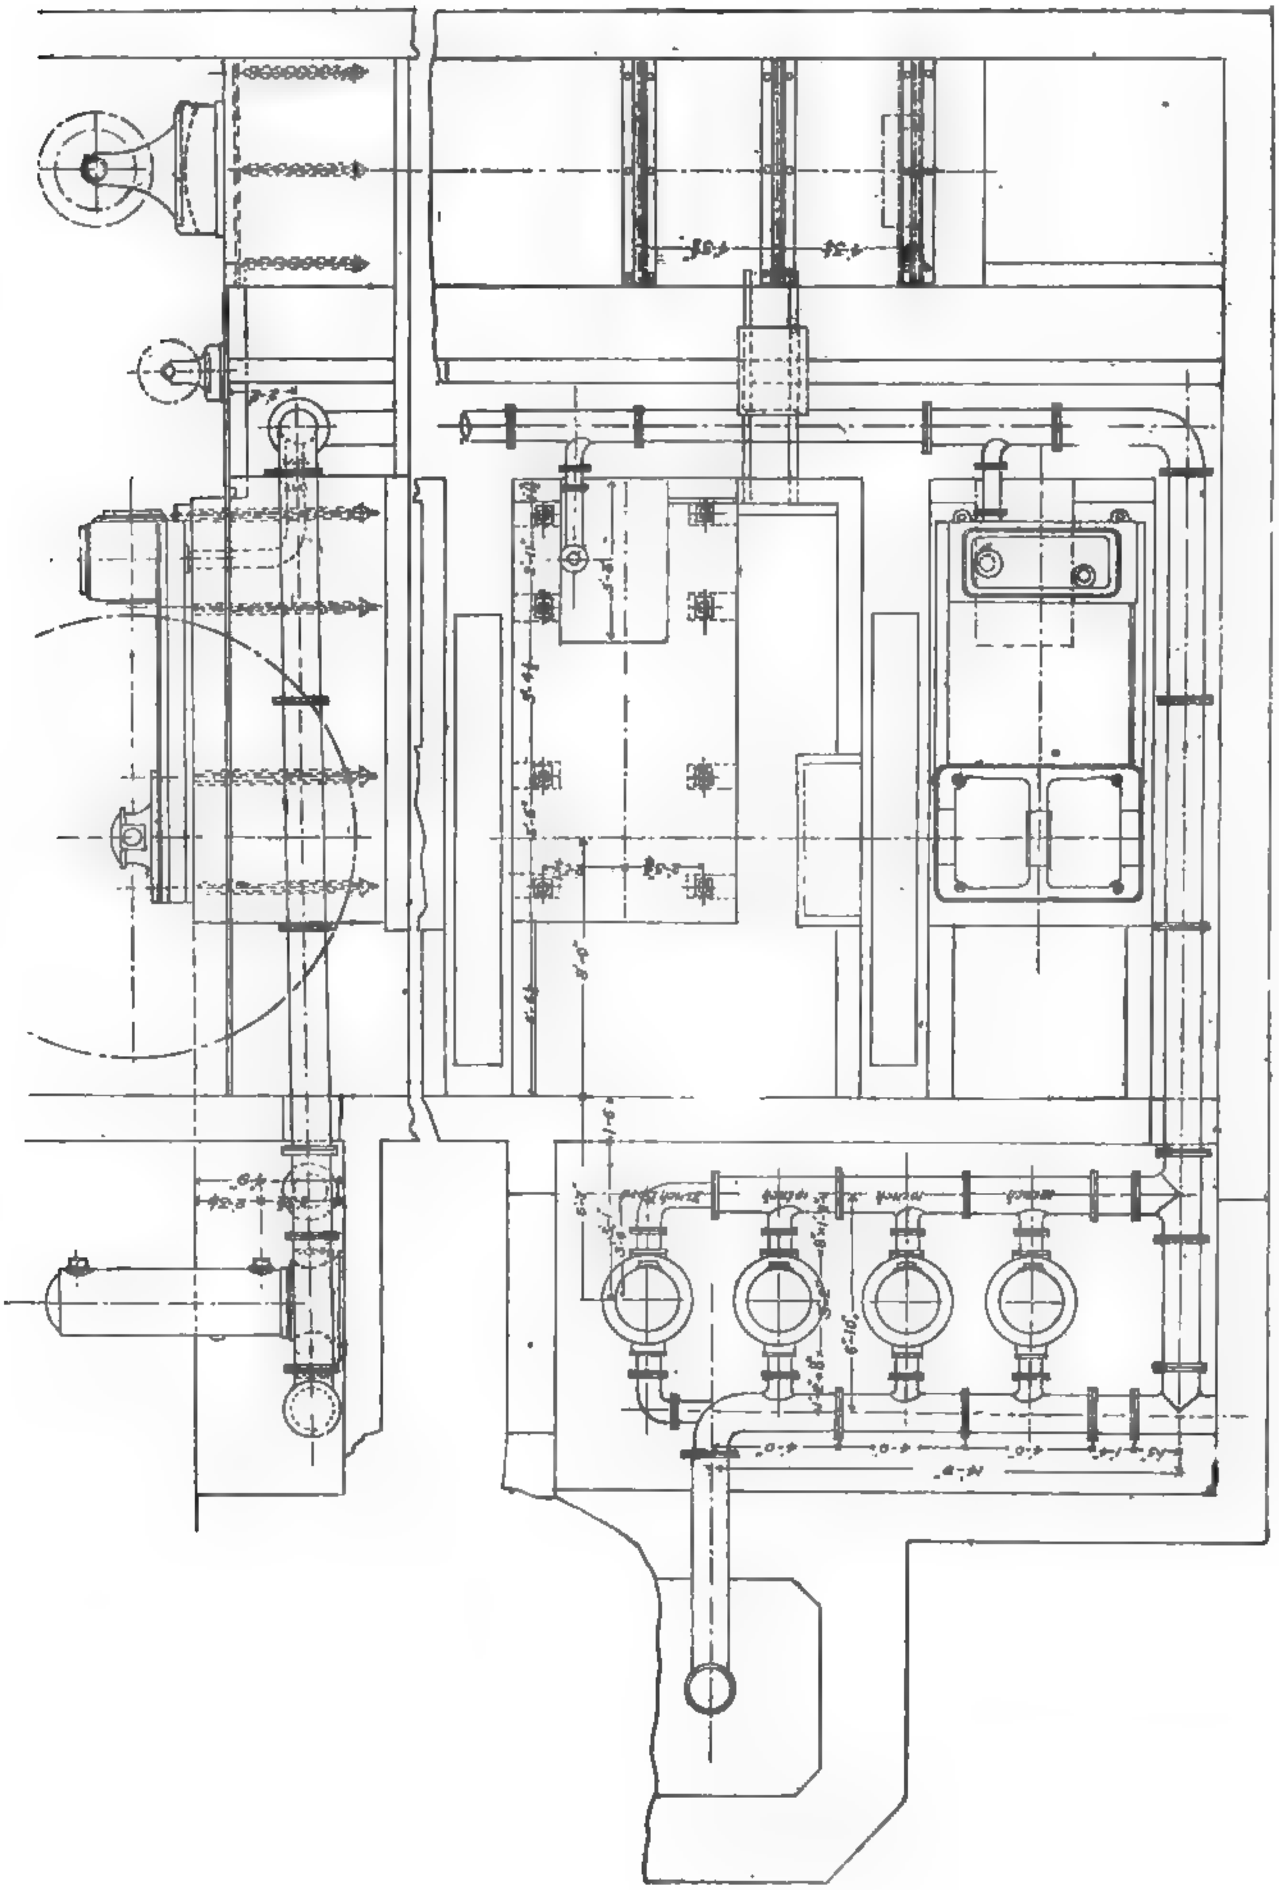
Electric Communication on Trains.—We have often wondered why more British trains are not furnished with electric safety communication with the guard and driver, instead of the ancient and often useless outside cord, for electric signals are common enough on the continental trains. We notice that a trial was made last week on the "Dandie" train running between Glasgow and Helensburgh, of a new system of electric communication introduced by Messrs. Shiels and Elliott, of Glasgow, which promises well. In the continental signals the handle is kept in place by a cord with lead plug attached, which can be broken by a forcible movement, which seems to us probably rather preferable to the necessity of breaking a glass and pushing a button. The latter is the method adopted on the Shiels-Elliott system, which embodies besides signal bells on engine and guard's van, and a red semaphore which protrudes from above the carriage when the signal is rung. This, of course, renders possible the

arrival of aid in the shortest time. The bells are connected by two trunk wires, which are carried throughout the length of the train, while two branch wires—one from each trunk wire—are led into each compartment, and terminate in an electric push placed under the parcel rack, and protected by a metal cap with a small circular pane of glass in the front of it, which the passenger breaks in order to press the alarm push, the glass being specially prepared so as not to injure the hand of the person breaking it. The connections are made by having at each end of the vehicle a tubular bracket carrying a flexible hose-pipe with a half-coupling at its end. These half-couplings are so arranged that when the carriages are brought together they can be interlocked by a simple movement similar in action to the coupling of the Westinghouse air-brake. The contact-pieces of the coupling are made on the double-wedge principle, pressing firmly on each other when the coupling is locked, and ensuring a good electrical connection. The coupling is also so constructed that should it have been omitted to unloosen it during shunting operations, it unlocks itself automatically, thus avoiding any damage being done to the electric system. The trial was considered entirely successful.

Newbury.—A correspondent, writing to the *Newbury Weekly News*, goes with some detail into the cost of proposed electric lighting in that town. After dealing with the question of using Dowson gas (a question we should like to see further discussed) he goes on to give "figures forwarded by one of the largest electric lighting companies in London, who are prepared to deliver and erect the various machines required at the undermentioned prices—viz., dynamo £500, storage batteries £500, transformer £550—the machines to be equal to the supply of an installation of 2,000 lights; and, further, these prices are subject to a discount of 30 per cent. for cash, so that the total cost of the machines will be about £1,000 net. The cost of the mains for the area designated in the order applied for by the Corporation will not amount to £2,000, including casing, breaking up the streets, and making good, and that sum will be considerably reduced if the mains are laid in the trenches opened for the sewers, so that the total cost of the requisite machinery and mains will not amount to more than £3,000, leaving £2,500 for alterations to mill, compensation for tenants' rights and contingencies; probably about double the amount that will be required. With regard to repairs and renewals," he continues, "provided the dynamos are of good manufacture and properly fixed, almost any electric lighting company will contract to keep them in repair for 5 per cent. per annum, and would make a good profit by so doing, as many of the recent pattern dynamos are not costing 2 per cent. for repairs. The accumulators will probably not require to be used more than 20 days throughout the year, and 1½ to 2 per cent. will amply cover their repairs and renewals. The transformer will not cost more than 1 per cent. to keep in repair; one that has been working at a very large installation in London has only cost 17s. for repairs during the 2½ years that it has been running. I purposely left out of my account the cost of repairs to mains as I knew that such enormous strides had been made in the improvement of the casing and other important details, that the figures of repairs of even two years ago would be fallacious, and I am now informed that many of the large companies will lay the mains and then keep them in repair at from 1½ to 2 per cent. per annum; so now we can total up the cost of repairs and renewals. Dynamos 5 per cent. on, say, £350, £17. 10s.; accumulators, say 2 per cent. on £350, £7; transformers, say 2 per cent. on £400, £8; mains, say 2½ per cent. on £2,000, £50; total, £82. 10s." As to estimate of receipts, he adds, 10s. per lamp supplied is an exceedingly low revenue, probably lower than any known. Mr. Preece's well-known estimate was based upon every lamp connected with the mains, and some had only been so connected a very short time.

Coast Communication.—Letters have again appeared in the *Times* upon that all-important subject to Great Britain as a kingdom—as a naval and commercial power—the safe coast communication by telegraph or telephone. Mr. A. Pendarves Vivian, in a letter dated January 1, 1892, points out that as to difficulty of connection to isolated lighthouses, we know that in the case of submarine cables, the cable has even now often to be protected by a channel cut in the rocks, cemented over afterwards. It would be possible also, he suggests, to protect it by cast-iron pipes. (We have before us at this moment a new flexible steel casing for cables, which it is possible might be used.) The difficulties, as Mr. Vivian states, are not new, for they have to be contended with, more or less, in submarine cables leaving a rocky coast, as at the South of Cornwall—near Penzance. "With regard to lightships," he rightly says, "there is more novelty in the difficulties to be overcome, but not for one moment would I believe that the same skill and ingenuity which are now so continuously shown by our electrical engineers would not speedily surmount them. I feel confident that any injury to the cable, such as would occur by the constant motion and the swinging of the ship, would be provided against, and that, if necessary, a movable joint would be forthcoming which would secure a perfect metallic contract, which we all know is a necessity. The whole matter resolves itself into a question of expenditure, and that it will be costly no one can doubt; but so are lifeboats, lighthouses, and lightships, all of which have the same object in view—namely, the protection and safety of valuable lives and cargoes." Mr. Robert Bayly, of Plymouth, writing on the same date points out that communication of the "Sunk" Lightship by telegraph and telephone to Walton-on-Naze when he visited it in 1889 was perfect, the telephone especially being preferred even in the worst weather. The experiments there extended over five years, and were apparently perfectly successful. Really, this question of coast communication is becoming intolerable. Mr. Preece has pointed out—and we have emphasised the fact—that the matter does not lie within the business of the General Post Office, which is a commercial agency for carrying messages and letters, and not for the saving of ships. This latter is a national affair, and all that is required is to introduce a short Bill next session for an appropriation of, say, £100,000, and then authorise the Post Office to carry out this work, which they are perfectly competent and willing to do. The thing would then be done, and a standing disgrace to England as the first naval Power of the world, which yet cannot take the simplest telegraphic precautions for safety of her ships, would be removed. We should like to ask what are the Institution of Electrical Engineers doing in this matter. At one time they were all telegraph engineers, with an energy to overcome all difficulties—technical and financial. What, we may ask, is the organ of the telegraph and submarine cables doing to stir up the authorities to tackle this problem, and that not less important, the establishment of underground land lines. Let the Institution of Electrical Engineers, the London Chamber of Commerce, and the Plymouth Chamber of Commerce put their heads together and bring in a Bill for the purpose so defined and so thoroughly needed. This should command the sympathies of everyone—Press and members of Parliament, alike with men of business the kingdom over, and no time should be lost in putting the matter into practical form.

SYDENHAM ELECTRIC LIGHT STATION.



DETAILS OF EXHAUST PIPES AND WATER HEATERS. Scale ½in. to one foot.

THE CRYSTAL PALACE EXHIBITION.

According to our usual practice, we visited the majority of stands on Wednesday in order to ascertain the prospects of readiness for the private Press view, held to-day (Friday). In many instances the exhibits will be quite ready, in others partially ready, but alas! in many, the unpreparedness must lead to considerable delay before the stands are complete. No doubt a vast amount of final preparation will be got through between the time of our visit and the actual opening. The Machinery Annexe seems to be the most backward, yet there will be plenty of material for the visitor to examine from the moment of opening. Commencing a rapid survey from the north end, it was seen that the elaborate screen of incandescent lamps erected by the Edison-Swan Company, and which will be one of the greatest attractions of the exhibition, was in a forward state. Just below this screen is the large and varied exhibit of the Postmaster-General, comprising the historical and present-day apparatus used in telegraphy. Almost the whole of the exhibits are now in position. Close by is the exceedingly pretty stand of the Mining and General Company—a study in black and red—the exhibits upon which we understand will be quite ready. Mr. White, of Glasgow, has a splendid display of Sir W. Thomson's measuring instruments, fully complete. Messrs. Nalder Bros.' stand in the same quarter is ready, but not fully equipped. Still, the show of their make of instruments should be a good one. Messrs. Evered, of renown in the production of artistic fittings, have nearly completed their exhibit, as have Messrs. Joel and Co.; while the W. T. Henley Company and the Fowler-Waring Cables Company, exhibit cables and wires of varied descriptions.

One of the most interesting features of this exhibition as showing the development of telephone enterprise, will be the concert-room of the National Telephone Company, where on payment of a small fee the public will have the opportunity of listening to the music which is being performed at theatres in London, Birmingham, Manchester, and Liverpool.

It must be allowed that the National Telephone Company and the Western Electric Company adjacent have two of the best-arranged stands, and should be quite ready at the opening ceremony. Of the large engineering firms, Woodhouse and Rawson, Crompton, the Brush Company, Siemens Bros., and Messrs. Johnson and Phillips, come one after the other, and each of these stands will have sufficient apparatus of interest to make a good show, though it is perfectly evident some of them will not be completely ready at the opening. The General Electric Company will have some very effective exhibits, but we deem it preferable not to enter upon detailed description till the exhibition is fairly opened. Our readers require a little more information than a mere catalogue list. Many of the smaller stands at the sides of the Central Nave will be quite ready, and will fully exhibit the specialities of the various manufacturers. Altogether the exhibitors may be congratulated upon the vast amount of excellent work put in since the commencement of the New Year, but even the extra week's grace has not brought about that completeness which the public look for and expect.

A visit to the galleries on Wednesday last showed that considerable progress has been made since last week, and that, though a good deal still remains to be done, some of the stands will be in a fair way to completeness by next week. We doubt, however, that several weeks must elapse before the odour of paste and polish tones down. The idea of exhibiting examples of living-rooms, conservatories, and so on, furnished and decorated in various styles is excellent, and marks the advance that has been made in practical electric lighting since the 1881 exhibition. It also shows that decorators and upholsterers are fully aware of the advantages offered by the incandescent lamp, for here we find two such firms combining to exhibit their wares under its light. We are afraid, however, that the desire for more light, which has been growing steadily during the last decade consequent upon the introduction of electric lighting, is likely to lead to error. Whilst it is perfectly true that we want more light in our streets, stations, and large buildings—and since electric lighting led the way and educated the public, have, to a certain extent, got it at the hands of the electrical or gas engineers—it does not follow that the object of introducing incandescent lamps into our houses is to obtain more light. It has been repeatedly pointed out that to have too much light in a room is almost worse than not to have enough. The reasons why we use electric lights are because they are cleanly, and do not injure costly decorations, because they do not vitiate the air, and because they can be placed exactly where we want them. There is a flexibility about the incandescent light which is wanting in all other systems of illumination. Now, this being so, we think it will be a pity if the various firms who are exhibiting interiors go in for demonstrating the illuminating power of the electric light rather than its flexibility and adaptability. We don't want to see floods of light in these model rooms, but we want to see them really well lighted—that is, to find the light just where it is required. For instance, we very much fear that one of the dining-rooms exhibited is to have a lamp depending from every square yard of the ceiling, the wires coming through certain projections in the decoration. If this is the intention we think it will be a mistake. True, the room will be flooded with light reflected downwards by the white ceiling, but there will be too much of it, and the method of its introduction is not to be commended. Every room requires to be lighted in a different way, because each is used for a different purpose, and we hope this fact will be fully recognised at the Palace, and, as we have said above, the beautiful adaptability rather than the illuminating power of the incandescent lamp brought before the public with marked emphasis. But to chronicle the progress made since our last visit. The stand of Messrs. Rashleigh Phipps, and Dawson is rapidly nearing completion, and one can get a fair idea of the appearance which the rooms will have when the finishing touches have been put to them. In the conservatory the rockwork is in evidence, and this should prove quite a favourite spot for visitors, as it will command a kaleidoscopic view of the main floor below. The Old English hall, Italian dining-room, and Japanese drawing-room have all taken on form and colour, and a few days now will make a wonderful difference in their appearance.

MESSRS. H. AND J. COOPER, of Great Pulteney-street, are also well forward with their dining-room, bedroom, and boudoir. The latter should afford many opportunities of showing what can be done with the incandescent lamp. Many ladies are halting between two opinions in the matter of electric lighting. They are weighing the disagreables of "wiring," which they, and especially their sterner halves, place in the same category with "spring cleaning," "papering and plastering," etc., against the advantages which will accrue from turning out the gasman and bringing in the electrical engineer. Nothing will give the balance a kick in the right direction more quickly than the sight of a well lighted and cosy boudoir. This, no doubt, Messrs. Cooper will take care to provide them with.

MESSRS. ALLEN AND MANNOOCH, of Mount-street, Berkeley-square, W., are working hard to complete their exhibit, which includes a dining-room, with dark oak furnishing and panelling, a bedroom and a boudoir. These rooms will no doubt attract considerable attention when they are finished We hope, however, that the firm will not try to overdo the lighting. Too many lamps, like too many cooks, sometimes spoil the best of—intentions.

Mr. GILES, of High-street, Kensington, has a large stand which is in a fairly forward condition. It will comprise a suite of rooms designed to show what he can do in the way of decorating and furnishing.

Mr. C. B. HARNESS'S gorgeous temple, wherein he will 'tice the B.P. after the manner of the nursery rhyme, was filled with paperhangers and decorators at the time of our visit, and will no doubt subsequently be crammed with the believing. A huge signboard close at hand indicates that this is the way to the camera obscura. Mr. Harness's temple has been designed, and excellently well designed too, by Messrs. Benison and Bargman, architects, of 16, Craven-

street, Strand, and has been put up by Mr. E. Triggs, builder, of 95, The Chase, Clapham, S.W.

In close proximity to this stand is a suite of rooms which are being decorated and furnished by MR. W. POOLE, Church-road, Upper Norwood, and MR. ELDRIDGE, of Westwood-street, Upper Norwood, the two, although trading separately, having, we understand, combined to exhibit their different wares under the soft rays of the electric light. The suite will be very complete, and will comprise hall, dining-room, drawing-room, bedroom, boudoir, and bathroom.

Close at hand, MESSRS. SHIPPEY BROS. are making a special feature of American goods, and will show lamps and motors in a hundred and one different shapes and sizes, whilst giving practical illustrations of the many uses of the latter. We are also promised something novel in the shape of devices for attracting the public, but of these we shall be able to say more when the promise has been fulfilled, as no doubt it will.

ELECTROLYSIS OF GOLD SALTS.

BY ALEXANDER WATT.

(Continued from page 17.)

It should be mentioned that many of the solutions of gold salts prepared for use in these experiments were of an exceedingly unstable character, some of them being very readily decomposed by light, in some cases being reduced to the metallic state, often in a more or less crystalline form; while from some of the solutions prepared from the teroxide the metal deposited in the form of protoxide soon after the solutions of the persalt had been effected. This separation of the protoxide occurred in some instances when the solution of the persalt had been obtained without the aid of heat, but more readily so when the respective liquids were heated. In such cases, therefore, it was found necessary to electrolyse the solutions of the unstable salts referred to almost immediately after their preparation—that is, during the brief period that the metal remained in solution.

12. *Aurochloride of Sodium by Electrolysis.*—A strong solution of chloride of sodium was electrolysed with the current from three cells, a gold anode and silver cathode being used as before. Chloride of gold at once formed at the anode, and in a few minutes after a deposit of gold was received upon the silver plate.

13. *Aurochloride of Potassium.*—A solution of chloride of potassium, being electrolysed with the same current as above, yielded a deposit of gold upon a silver cathode in a few minutes after immersion.

14. *Aurochloride of Magnesium.*—A solution of chloride of magnesium under the same conditions as above rapidly dissolved the gold anode, and a deposit of the metal was received upon a silver cathode in two or three minutes after the electrodes were immersed in the liquid.

15. *Aurochloride of Barium.*—A solution of chloride of barium, being electrolysed with the current from three Daniells, dissolved the anode freely at once, and a deposit of gold formed on a silver cathode in a few minutes after.

16. *Aurochloride of Strontium.*—A solution of chloride of strontium, electrolysed under the same conditions as before, yield a solution of gold, from which the metal became deposited upon a silver cathode in a few minutes after immersion of the electrodes.

17. *Teracetate of Gold.*—A solution of this salt was formed by digesting moist hydrated teroxide of gold in ordinary commercial acetic acid; a small portion only of the oxide became dissolved. The solution, after being moderately diluted with water, was electrolysed with the current from four Daniell cells, when a deposit of gold slowly formed upon a silver cathode. After a few minutes, green non-reguline metal formed upon the film first deposited.

18. *Tersulphate of Gold.*—Hydrated teroxide was digested ? dilute sulphuric acid, and the resulting solution was electrolysed with the current from three cells in series. After a rather long immersion, a film of gold gradually formed upon a cathode of silver; the amount of gold in solution was, however, small, and there appeared to be no action upon the gold anode.

19. *Terlactate of Gold.*—In some former experiments in the electrolysis of metallic salts the writer had found that lactic acid exhibited a higher solvent power for metallic oxides and carbonates, and even upon some metals, under electrolysis, than could have been expected from so comparatively weak an acid. This fact induced him to ascertain the behaviour of this acid in respect of gold. A strong solution of lactic acid being prepared, a portion of this was added to a quantity of moist hydrated teroxide of gold, and the mixture repeatedly stirred for a few minutes. The mixture was then placed on a filter, and a portion of the clear liquid, which had a purple tint, was afterwards tested with a solution of chloride of tin, when the purple of Cassius at once formed, indicating the presence of gold in the solution. The clear solution was then electrolysed with the current from three Daniell cells in series, a gold anode and strip of platinum foil being used as the electrodes. Soon after the circuit was completed, a dark green film appeared upon the platinum, while the anode, which at first presented a rather dull surface, became somewhat brighter. The green deposit, which, as before stated, represented gold in a finely-divided (and non-reguline) state, was next heated by holding the platinum foil on which it was deposited over the flame of a spirit lamp, when after a few moments the gold film assumed the more perfectly metallic state, but apparently in two different conditions—one part of the film assuming the characteristic colour of fine gold, but the remaining portion (at the lower part of the cathode) was of a deep orange-red colour. The gilt portion of the platinum was next dipped into warm nitro-hydrochloric acid, when the yellow part of the film readily dissolved, but the orange-red portion was very tardily acted upon, and fell from the plate in small grains of a deep red colour.

20. *Lactate of Gold by Electrolysis.*—An attempt was next made to determine whether lactic acid, under the influence of the current, would act upon the gold anode, forming a solution of gold from which the metal could be deposited. For this purpose, a strong solution of lactic acid was electrolysed with the current from four cells, when in about a quarter of an hour or so a green film appeared on the silver cathode as before, proving that the anode had been somewhat speedily acted upon by the acid. A platinum cathode was next used, which received a yellow film of gold shortly after immersion.

21. *Purple of Cassius by Electrolysis.*—A rather weak solution of protochloride of tin was electrolysed with the current from two cells, a gold anode and silver cathode being used. Almost immediately after immersion of the plates, the purple of Cassius formed at the anode, and gradually deposited somewhat copiously at the bottom of the vessel. This method of producing the purple salt might be found useful.

22. *Terchloride of Gold in Hydrochloric Acid.*—A solution was prepared by dissolving gold in aqua regia and carefully evaporating the terchloride to dryness. A portion of the dry gold and salt was then dissolved in hydrochloric acid. The resulting solution was afterwards considerably diluted and electrolysed with the current from a single Daniell cell. A silver cathode immersed in the liquid received a deposit of gold of very good colour very promptly, the film being firmly adherent. It is not improbable that a solution thus composed might be found useful for some purposes, if worked with care. The liquid, however, must be weak and the current low.

23. *Teroxide of Gold in Nitric Acid.*—Teroxide of gold was digested in dilute nitric acid, and the solution, after being diluted, was electrolysed with the current from three cells. Gas was given off at both electrodes, and metallic gold deposited upon the silver cathode.

24. *Saccharate of Gold by Electrolysis.*—A strong solution of saccharic acid was electrolysed with the current from four cells, when the gold anode became very slowly

dissolved, and in about half an hour a film of gold of a grey colour formed upon a platinum cathode, which readily dissolved in aqua regia. A silver cathode was next substituted, upon which the metal deposited of the characteristic yellow colour of gold at first, but after a time the film acquired a somewhat dirty colour, indicating the pressure of non-reguline metal—probably the *grey* condition before noticed.

25. *Electrolysis of Bisulphate of Potassium.*—A solution of the bisulphate was electrolysed with the current from four cells, a gold anode and silver cathode being used. Gas was liberated at both electrodes, and in the course of about half an hour, or somewhat less, a slight film of gold appeared upon the silver surface.

26. *Aurate of Ammonia in Lactic Acid.*—A solution was prepared by dissolving aurate of ammonia in a strong solution of lactic acid. The solution, after being moderately diluted, was electrolysed with the current from a single cell, when gold of good colour at once became deposited upon a silver cathode.

27. *Gold Teroxide in Tartaric Acid.*—Hydrated teroxide of gold was digested in a strong solution of tartaric acid for some time, and the liquid, after being moderately diluted, was tried with the current from three cells. Gas was evolved at both poles, and a slight film of gold slowly formed upon a cathode of silver.

28. *Electrolysis of Phosphoric Acid.*—A strong solution of phosphoric acid was electrolysed with the current from four Daniells. In about half-an-hour after immersion of the plates it was found that a deep orange-red salt had formed on the anode, which fell from the plates in transparent flakes. A slight film of metallic gold deposited on the silver cathode.

29. *Electrolysis of Vanadiate of Ammonia.*—A strong solution of vanadiate of ammonia was electrolysed with the current from three cells, when after a short time the (colourless) solution acquired a rich yellow colour. At the bottom of the vessel minute crystals of a deep red colour appeared, and gold of a green colour and non-adherent formed upon a platinum plate. This deposit when moderately heated assumed a yellow colour. A silver cathode being substituted, this slowly received a slight film of reguline gold of the usual colour.

30. *Teroxide of Gold in Phosphorous Acid.*—Teroxide of gold was digested in a strong solution of phosphorous acid, and the solution, after being filtered, was electrolysed with the current from four cells. A very slight deposit of gold formed on the cathode, but a long immersion failed to yield a film of any thickness.

31. *Electrolysis of Phosphorous Acid.*—A strong solution of phosphorous acid was electrolysed with the same current as the last, and after a rather long immersion, a silver cathode became slightly coated with a film of gold. On examining the anode the immersed surface was found to be coated with a deep orange-coloured salt, which separated in transparent flakes, much resembling both in colour and appearance the flaky film referred to in experiment 28, and in several other experiments.

32. *Electrolysis of Chlorate of Potassa.*—A moderately strong solution of chlorate of potash was electrolysed with the current from three cells. Gas was given off at both electrodes, but otherwise there was no apparent action for some time; after a few minutes, however, it was observed that a profuse quantity of flat scaly crystals floated on the surface of the solution. On examining the anode at this time, it was found to be coated with a bright blue film, which was insoluble in the liquid.

33. *Electrolysis of Hydriodic Acid.*—A solution of hydriodic acid being prepared, it was determined to ascertain if it would dissolve gold from the anode by electrolysis. For this purpose the current from two Daniells was first tried, when the liquid nearest the anode at once assumed a yellow colour, but as there was no deposit of gold upon the silver cathode a third cell was put in series, soon after which black flakes fell from the anode and deposited at the bottom of the vessel. On examining the cathode at this time it was found to be coated with pale straw-coloured gold.

34. *Gold Teroxide in Hydriodic Acid.*—Moist hydrated teroxide of gold—obtained by adding a solution of potash to the terchloride—was digested in a strong solution of hydriodric acid, in which it dissolved rather freely. The solution thus obtained was electrolysed with the current from three cells, when a deposit of green, non-reguline gold formed upon the silver cathode at once; when this loose deposit was wiped off with the finger, a film of yellow reguline metal was found beneath, as is frequently the case when the green form of gold is deposited. To prevent the formation of this variety of the metal, and to obtain a fully reguline film, the solution was diluted and one cell disconnected from the series, when the metal deposited in better condition, but more especially when the cathode was gently moved about in the solution.

35. *Electrolysis of Iodide of Sodium.*—A solution of iodide of sodium was electrolysed with the current from three cells, when the liquid nearest the anode immediately acquired a yellow colour. The operation was then left undisturbed for about 10 minutes, at the end of which time the cathode was examined, when it was found to be coated with a film of gold in the green, non-reguline condition.

36. *Electrolysis of Iodide of Ammonium.*—A solution of this salt, electrolysed under precisely the same conditions as in the last experiment, soon acquired a yellow colour, and the cathode, as before, was coated with a film of green, non-reguline metal. When the solutions in this and the last trial were diluted and the current reduced, the gold deposited, though somewhat slowly, in the yellow, reguline state.

37. *Gold Teriodide in Hyposulphite of Soda.*—Hydrated teroxide of gold, precipitated by potash from the terchloride, was digested in a solution of hyposulphite of soda, and the resulting liquid electrolysed with the current from three cells. A film of gold, of a good rich colour, and firmly adherent, was promptly deposited upon a silver plate.

38 *Gold Teroxide in Citric Acid.*—Hydrated teroxide of gold was digested in a strong solution of citric acid, and the liquid, after filtration, was electrolysed with the current from three cells. Gas was freely given off at both electrodes, and after a few minutes' immersion a slight film of gold appeared upon a silver cathode. The amount of metal in solution was, however, very slight, and there was no apparent solvent action upon the anode.

39. *Gold Protiodide in Pyrophosphate of Soda.*—Iodide of gold was digested in a strong solution of pyrophosphate of soda. The current from four cells was found necessary to obtain a deposit upon a silver plate, and this only assumed the form of an iridescent film. Gas was given off at both electrodes. On heating the plate to near redness the film still retained its iridescent character, but the colourations were rendered more vivid and brilliant by the heat to which they had been subjected.

40. *Teroxide of Gold in Benzoic Acid.*—The precipitate thrown down by carbonate of potassa from a solution of gold terchloride, and the mixture afterwards boiled, was digested in a hot solution of benzoic acid, and the still warm solution was then electrolysed with the current from four cells. Gas was evolved at both poles, and a slight film of gold, of a yellow colour, was deposited upon a silver plate. A fifth cell was afterwards added to the series, when the deposited gold assumed a dark colour.

41. *Teroxide of Gold in Malic Acid.*—The teroxide precipitated by carbonate of potash, and treated as before, was digested in a strong and warm solution of malic acid. The solution was then tried with the current from three cells, but there being no apparent action, a fourth cell was added, when gas was liberated at each electrode, and a dark—almost black—film formed upon the silver cathode, which was very adherent. When heated over the flame of a spirit lamp, the film became iridescent, but when the surface was rubbed yellow gold appeared attached to the silver beneath.

(To be continued.)

REPORT ON TRIALS OF A 100-UNIT PARSONS STEAM TURBINE DYNAMO AT HEATON WORKS, NEWCASTLE-ON-TYNE.

BY PROF. EWING, F.R.S.

The machine tested in December last is, I am informed, the first condensing steam turbine that Mr. Parsons has built. Its shaft was designed to carry six small and one large plate or disc, each fitted with a series of rings of turbine blades, the large plate being specially designed to deal with low-pressure steam. After passing it, the steam was exhausted into a jet condenser of novel design, the pump of which was driven by a separate donkey engine. The turbine rings were of the outward flow type.

The turbine was designed to work with steam at an initial pressure of 140lb. per square inch, but on the occasion of the trials it was not practicable, for want of a suitable boiler, to use a pressure of more than 95lb. per square inch. The first and second plates with their turbine blades were accordingly removed, and the tests were made with the remaining four small and one large plate. The effect of this was to make the results of the trials less favourable, as to economy in steam consumption, than they would have been had the full initial pressure of 140lb. been available.

In line with the turbine shaft, and directly coupled to it, was the armature of an alternate-current dynamo capable of yielding 100 kilowatts, or 100 Board of Trade units of electrical energy per hour, and wound for a potential of 2,000 volts. The exciter was a distinct small dynamo of the continuous-current Gramme type, which was also mounted on a prolongation of the turbine shaft.

The turbine ran at a speed of about 4,800 revolutions per minute, and the armature was wound with a single coil, so that the frequency of the alternations was about 80 complete periods per second.

The whole machine, comprising the turbine, dynamo, and exciter, weighed about four tons; its length was about 14ft., and its greatest breadth barely 3ft. It stood on three cast-iron pedestals resting on an ordinary concrete floor. There were no holding-down bolts or special foundations, and none seemed to be required. The machine ran almost without vibration.

In the trials the current generated was spent on a bank of resistance coils consisting of open spirals of iron wire strung on wooden frames. The output was varied, in successive trials, from about 20 units per hour, or, say, one-fifth load, to 100 units per hour or full load. The loads spoken of are the amounts of electrical power spent in the external circuit, and do not include the work done by the exciter in supplying current to the field magnets of the main dynamo. (The output of the exciter was about 2½ units per hours.)

In two additional trials there was no external load beyond what was necessary for measuring the potential.

The experiments were arranged to give complete information of the amount of steam used by the turbine under all grades of output from full load to zero.

The electrical output was taken to be the product of the effective volts at the dynamo terminals into the effective amperes. The volts were measured by aid of a 2-h.p. transformer, which transformed down in the ratio of 1 to 10, and a pair of Cardew voltmeters. To test the accuracy of the professed ratio of transformation, the volts were on one occasion read by applying a Cardew voltmeter to successive portions of the bank of resistance coils (then grouped in series), so that the potential was directly determined by summing up the readings. This determination was found to agree exactly with that obtained by means of the transformer.

The Cardew voltmeters were themselves tested by comparison with a third Cardew, which in its turn had been standardised by help of one of Sir William Thomson's balances. They were found to be correct.

The current was measured by (1) an Evershed gravity ampere meter, and (2) a Siemens electro-dynamometer. These were connected in series in several of the trials, and found to be in perfect agreement. The Evershed ment had been tested against a Thomson balance.

The consumption of steam in the turbine was measured by passing the feed-water through a measuring tank, the capacity of which I checked. Steam was supplied from an old boiler of the locomotive type at a pressure of 90lb. to 95lb. per square inch. The steam-pipe was too small, and the loss of pressure between the boiler and the turbine must have been considerable, especially in the full-power trials.

In the full-power trials this boiler was insufficient to supply all the steam, and another boiler was joined to it. It was then impracticable to measure the feed, and the amount of steam passing through the turbine was estimated in these trials by measuring the rise in temperature of the water discharged from the condenser, in conjunction with the amount of the water, as gauged by means of a weir. This rise in temperature and the head over the weir were noted in all the trials, so that when the feed was directly measured a constant was determined which could be applied in cases where a direct measurement of the feed was impracticable.

The boiler was old and leaky, but the amount of water which fell to be deducted from the whole feed on this account was repeatedly determined. The allowances made for leakage are certainly not excessive, and do not in any case affect the full-power trials materially.

The steam required for (1) the feed-pump, (2) the air-pump, was supplied by a separate boiler, and is not included in the quantities that are stated below.

The vacuum ranged from 28½in. at light loads to 26½in. at full load. The temperature of the cold well varied from 5deg. C. to 18deg. C.

The trials extended over three days—December 12th, 14th, and 15th, 1891. The turbine was kept running, without change of load, long enough in each case to secure a uniform regime, and to prevent any material error from being caused by an inexact reading of the water-gauge glass on the boiler. The machine ran without any hitch throughout all the trials.

The following are the observed results. The trials distinguished by an asterisk are those in which the consumption of steam was inferred from the rise of temperature in the injection-water. In the other trials it was measured directly, as feed-water.

Electrical output in units generated per hour.	Steam used in the turbine in pounds per hour.	
0·3	510	492 (mean)
0·3	475	
20·8	1,120	
31·2	1,350	
48·5	1,875	
65·9	2,460*	
66·5	2,580	
93	3,530*	
100	3,600*	

These results are also shown graphically in the accompanying curve, which shows the relation of the number of pounds of steam used by the turbine per hour to the number of electrical units generated per hour.

It is convenient also to express the results in another way, by stating the number of pounds of steam used per unit generated, at various rates of output from full load downwards. These quantities, obtained by measurement from the curve, are given in the following table:

Output in units per hour.	Number of pounds of steam used per unit.
10	77½
20	53
30	43
40	41
50	39
60	38
70	37½
80	37
90	37
100	37

It will be seen from these figures that the consumption of steam by this condensing turbine was 37lb. per electrical unit generated, when the machine was giving its greatest output; that the output might be reduced to, say, three-fourths of its greatest value without causing any sensible addition in the consumption of steam per unit; and that at half load the consumption was 39lb per unit. When the load is further reduced the consumption per unit increases,

as it does in all engines, on account of the work which is expended within the machine itself.

The consumption of 37lb. per unit at full load corresponds to 27·6lb. per electrical horse-power per hour; and the consumption of 39lb. per unit, at half load, corresponds to 29lb. per electrical horse-power per hour.

For the sake of comparison it may be added that in a good ordinary compound condensing engine of corresponding power the consumption of steam is usually about 20lb. per indicated horse-power per hour, which corresponds (allowing for necessary loss in transmission to the dynamo) to, say, 36lb. per unit. In the special type of single-acting high-speed engines made by Mr. Willans, and successfully used in many electric light stations, the consumption of steam at full load and at moderately full load is somewhat less. The best results in trials published by him show (with high pressure and triple expansion) a consumption equivalent to about 30½lb. per unit in a non-condensing engine and 25lb. per unit in a condensing engine, worked at full load; while at half load the numbers are about 43lb. per unit and 32lb. per unit respectively.

I have no doubt that if it had been practicable in the turbine tests to use the full pressure of 140lb. per square inch for which the turbine was designed (in place of a pressure of 95lb.) that the consumption of steam per unit would have been considerably reduced.

As they stand, however, the results must be admitted to demonstrate a very remarkable performance. They show that in respect of economy of steam, and therefore of fuel, at full or moderately full load, the Parsons turbine of the type and size tested now challenges comparison with good engines of the usual kind, while its comparative freedom from friction gives it an exceptionally high efficiency when lightly loaded.

Apart from the question of steam economy, the lightness and compactness of the turbine dynamo, its small first cost, the perfect ease with which it is started, its freedom from vibration, and the absence of any need for heavy foundations, are points much in its favour as a generator for central station work.

Mr. Parsons has been good enough to give me every facility for examining the construction of his turbines and dynamos. I see no reason to anticipate that the charges for maintenance, for oil, and for attendance will be larger than in the case of other engines I should rather expect them to be lighter, and this appears to be borne out by the experience of the Newcastle and District Electric Lighting Company, where turbine generators have been in use for about two years.

I had the advantage of seeing the plant at that company's station and of obtaining particulars in regard to wages and other items of current outlay from the superintending engineer and the secretary of the company, who were most willing to supply information.

In regard to first cost, the turbine generator is probably cheaper, in large sizes, than any combination of ordinary engine and dynamo giving equal output.

The machine tested had an electrical governor which regulated by causing intermittent admission of steam. The action of this governor was not entirely satisfactory, and Mr. Parsons informed me that he meant to substitute for it a modified form of a type of governor which has been found to work well at the Newcastle and district electric light station and elsewhere.

The turbine worked at its full load of 100 electrical units per hour without any sign of distress, and so far as could be judged was capable of giving a greater output without difficulty. The dynamo armature became hotter than is, in my opinion, desirable. This might be avoided by an alteration in the winding of the armature.

With a dynamo wound to give continuous currents, the consumption of steam in the turbine per electrical unit generated may be confidently expected not to exceed the consumption observed in these experiments.

GREENWOOD'S ELECTRO-CHEMICAL PROCESS.

A new process for the direct production of caustic soda and chlorine has been devised by Mr. J. Greenwood, and is now being introduced by the Caustic Soda and Chlorine Syndicate, Limited, of 58, Lombard-street, E.C. It has this week been inspected in operation by a number of gentlemen at the works of Messrs. Bowes Scott and Weston, Phœnix Wharf, Battersea. The passing of an electric current through a solution of common salt divides the latter into caustic soda and chlorine, but the principal difficulty hitherto encountered in placing any method of this kind on a commercial footing has been to prevent the recombination of the electrolysed products. It is claimed, however, that the inventor of the process in question has surmounted this obstacle by the use of a patent diaphragm and a compound anode.

Mr. W. H. Preece, who has made experiments with the plant, states that the commercial efficiency of the process is 75 per cent., and he is certain that in actual practice, and with further experience, even better results can be obtained. As far as the expense of producing electrical energy is concerned, he says that in the coal districts, with triple-expansion modern engines and dynamos, working continually at full load, the cost would amount to ⅛d. per kilowatt hour. The total cost of producing caustic soda and bleaching powder and liquor would, according to Mr. Preece, be little more than one-third of their present market value.

Dr. Gore, F.R.S., has drawn up two reports. He states that he is convinced of the scientifically practicable character of the method, and that nearly all the chief engineering chemical difficulties of the process appear to him to have been overcome. He also expresses the opinion that the amount of labour and the number of workmen necessary in the process, when carried out on a large scale, would probably be small in comparison with that required for producing the same quantities of the same products by the usual methods, because the entire process would be largely automatic.

Messrs. Cross and Bevan, of the laboratory, 4, New-court, W.C., find that the efficiency of the process has advanced to 80 per cent., as compared with 70 per cent. when preliminarily examined by them some months ago.

The plant laid down consists of five electrolytic tanks arranged in the form of a flight of steps, whilst the vessel containing the supply of brine is erected on a higher level than the top tank. This arrangement ensures an automatic circulation of the solutions. Each tank contains five compound anodes and six cathodes placed alternately, these being separated by diaphragms. The anode is formed of carbon plates having a metal core so as to increase the conductivity; it is specially treated so as to render it non-porous and unattackable by the chlorine gas which, it may be mentioned, is evolved on its surface. The cathode, on which is formed the caustic soda, is an iron plate. The patent diaphragm is of peculiar construction, being composed of strips of slate arranged in a longitudinal frame. These strips are placed at an angle of about 45deg., one above the other and on each side of the frame, an intermediate packing of asbestos fibre being used. The diaphragm and the anode constitute the two principal features of the process.

Each tank is divided into 10 anode or chlorine sections, and 10 cathode or caustic soda sections. The anodes and cathodes in each tank are arranged in parallel, and the five tanks in series. An E.M.F. of 4·4 volts, with a current of 10 amperes per square foot of electrode surface, is required to overcome the resistance of each tank. Vulcanite tubes are employed to connect the 50 anode sections, the inlet being at the bottom and the outlet at the top of each section. The cathode sections are similarly connected.

The working of the process is, briefly, as follows: The tanks are charged with a solution of common salt, and on a current being passed the solution is decomposed or divided into its constituents, chlorine and sodium. A secondary action occurs in the separation of the sodium, and this converts it into caustic soda. After passing out of the lowest tank the salt solution and the caustic soda are pumped back to their respective charging vessels, the former to be further decomposed and the latter to be further concentrated. The chlorine gas given off in the anode sections passes by means of branch and main pipes into four absorbing tanks. These contain lime and water kept in a state of agitation and which takes up the chlorine and transforms it into bleaching or chlorate liquor as required. The caustic soda formed in the anode sections is rendered more or less concentrated according to the particular purpose for which it is required.

The company state that the process will be of great importance to the paper, soap, and bleaching industries, and that it is also applicable to the production of sodium amalgam and chlorine for extracting gold and other metals from their ores, and caustic and chlorate of potash and other chemicals. This brief description of Mr. Greenwood's process is given, as the lawyers say, "without prejudice." So many processes have from time to time been put forward, and have failed, even when reported upon by the highest authorities, that a considerable amount of caution must be used. A process may be theoretically perfect, and seem commercial upon an experimental scale, though, when tried upon a large scale, it proves to be less successful.

Tudor Accumulators.—The Tudor Accumulator Company have issued an illustrated catalogue of some pretension. Besides information as to size and prices, chapters are given, one containing the reports on these accumulators by MM. Uppenborn, Kohlrausch, and Monnier, and others, and the other dealing with best methods of mounting accumulators. Directions for the care and management of the cells are given in a special chapter.

BOUND VOLUMES.

Vols. I. to VII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

1892.

It is usual at the commencement of each new year for the Queen to honour those in her realm to whom the Prime Minister for the time being believes honour to be due. Such honours are conferred for various reasons—mostly political. At times, however, other claims are held to be paramount, and the scientific world contributes its quota to those who receive these honours.

Few announcements will give more pleasure to the scientific world in general, and the electrical world in particular than, the announcement that a peerage is to be conferred on Sir William Thomson. In his person no one can complain that scientific pre-eminence is not rewarded, though it would indeed be difficult to add distinction to that he has himself achieved by his numerous practically useful inventions and deep mathematical researches. Elected President of the Royal Society last year, the highest purely scientific honour a native of the United Kingdom can receive, his elevation to the peerage is only a further step in his distinguished career. We have no need to allude to Sir William Thomson's achievements in science—they are too well known to our readers to require iterated mention, but we do not think his kindness and interest in struggling students, of whom he must have had an enormous number under his charge, has been brought to light. We remember one interesting example which will bear mention at this juncture, and illustrates the kindness of two men and the influence a little help will have upon a young man's life. The late Dr. Royston Piggott, who died recently at Eastbourne in the fulness of ripe age, was in early years Sir William's mathematical tutor, and kept his interest in his distinguished scholar. Dr. Piggott was always interested in promising young students, and one of his *protégés* was the son of a policeman who had taken to amateur electrical experiments. The doctor learnt of this, gave the lad lessons, and then asked the father whether he wished his son to be made an electrician. The father did not seem anxious for honours, but the mother was, and, armed with a letter of introduction to Sir William Thomson, she posted to Glasgow with the boy and a heap of electrical instruments. Sir William was not at home, but visiting at a country house in the neighbouhood. Not to be daunted, the hopeful mother took a cab, and, with the seat crowded with instruments, called at the house, and asked for Sir William, who came down from the billiard-room with a cue in his hand. With much amusement and interest he interrogated the couple, and finally made an appointment at the college in Glasgow, and found the boy a place. It is many years ago now, but this young man, we believe, soon after received an appointment as superintendent of telegraphs in one of the colonies, at a salary of some £600 a year—rather better than he might have hoped for in his native town. Numerous other cases might be quoted to show that

Sir William feels an interest in human as well as scientific problems. Nor have we probably heard the last of his contributions to the latter. It is possible, we hear, though not yet decided, that the title which Sir William will take will be that of Lord Kelvin, from the name of the once beautiful river which flows past the foot of the college grounds at Glasgow, and on which his windows look out. May he live long to enjoy his honours!

In our next issue we shall give a further series of portraits similar in style to those given in our last number. As far as possible our publisher will refuse to supply single copies of these special issues to casual purchasers. We do not cater for those who pick up an odd number of the paper now and again, but desire to do the best to provide suitable pabulum for those who are regular readers.

If in our issue of January 2, 1891, we felt constrained to say "the business problems that await solution to-day . . . are very similar to those awaiting solution a year ago," we should not be far from correct in restating that view. Yet there is a great difference in January, 1892, over January, 1891. Financiers were still very shy in 1891; they are still shy, but less so, because month by month electrical engineers are demonstrating the certainty and the suitability of electric lighting for general work. Then the great experiment of Lauffen-Frankfort—whatever may be the economical figures connected therewith—the great experimental departure of the year, has forced attention from those still inclined to scoff at the probabilities of electrical applications. English electricians have sadly attempted to belittle the adoption of polyphase apparatus. In public and in private they have denied there was anything good in the idea, but they find their continental and American *confrères* refusing to see in the same light. Let us admit that we have still much to learn about polyphase apparatus, and await further experimental and theoretic study before condemning the departure.

FINANCIAL.—Whether the future will see rotary-current apparatus pass into oblivion or develop into greater prominence, there can be no doubt it has proved the grandest advertisement for electrical engineering that the past year brought forth. It has helped other and more modest work in the eyes of the financiers, so that at the present time more than one energetic firm or company finds it less difficult to finance its new schemes than was found twelve months ago. It would not be right, however, to hint without qualification that "finance" was now easy, and would continue so. There are troubles looming ahead connected with companies whose prospects are thought to be bright. Long ago we suggested investment in low-priced shares—such as the Brush were then quoted—to some higher-priced ones. The market quotation is not always an indication of real value; there is such a thing known as making a price. We again reiterate in the strongest possible manner, avoid the highest prices and be content with the lower. With the exception that it makes financing difficult, we care little what the public gains or loses in its buying and selling shares. The public has no sympathy with those who correctly advise, and, on the other hand, the adviser often cuts his own throat by making enemies of those who are willing to pay for silence. The smash up of a big company, however, is harmful to the industry generally—hence our warning. There are few or none of the existing concerns past recall, and most of them with a moderate amount of care will prove good investments.

TRACTION.—The event of the year, so far as England is concerned, has been the installation of the Thomson-Houston overhead system of trams at Leeds. We gave a very complete description of this line at the time of the opening, and the experience of our friends living in the district is altogether in favour of the line. At the time of the opening ceremony we attempted to get the views of residents on the route, but, like most Yorkshiremen, they refused to commit themselves. A few days since, testimony unasked for was forthcoming, and, as we say, altogether in favour of the line. No doubt Mr. Graff Baker has had similar testimony from a number of people, but this outside praise cannot be unacceptable. The consensus of opinion being thus favourable, should lead to a rapid extension towards the centre of the town; and the success at Leeds, we trust, will induce other places to go forward. The City and South London, while it may not have fulfilled all the expectations of its promoters during its first year of existence, is undoubtedly gradually winning its way to success, and the experience gained thereon will be invaluable in the extensions to be undertaken in other quarters of London. The earliest of our electric trams—that of Mr. Volk's at Brighton—after undergoing vicissitudes of no ordinary kind, is still running satisfactorily, and is about to be greatly improved. The widening of the roadway has made it difficult to keep the rails clean enough to use one rail as a lead and the other as a return, so a third rail is to be added. Two new cars are being built by Messrs. Kerr, Stuart, and Co., which Mr. Reckenzaun will fit with motors. The other lines are much as they were. Mr. Holroyd Smith is to carry out an experiment at Halifax, and we have no doubt he will be as successful there as at Blackpool. What promises to be the great feature of the present year is the Liverpool overhead railway, the apparatus for which is being constructed at Wolverhampton.

The ACME ELECTRIC WORKS inform us that the past season has been the most successful that the firm has experienced, and the works have been fully occupied throughout the year, and, in fact, for the last four months it has been necessary to keep them going on overtime regularly. They have been favoured with a succession of orders from Government departments for heavy switchboard and other work, and have substantial current orders in hand. The present year has opened out in a very promising manner. With reference to the Teague patent electricity meter, this has now been developed into a commercial instrument, and the labours upon it

have been rewarded by important orders. The firm has considerably extended its plant in the instrument department, which enables rapidly-increasing demands to be met with facility. The new Acme patent ampere and voltmeter has turned out most successful, and has been received with much favour, and the demand for the same is steadily on the increase. The firm's well-known switches and fuses still maintain the prestige they have so long enjoyed, and business in this department is increasing rapidly.

BENHAM AND FROUD say, generally, that they have been very busily engaged in the manufacture of electric fittings of the highest class of art metal work throughout the whole year.

DRAKE AND GORHAM.—A review of the work done by Messrs. Drake and Gorham shows that country house lighting is on the increase, this firm having carried out about 50 installations, notably Wynyard Park, for the Marquis of Londonderry, 1,000 lights; Margam Castle, for Miss Talbot; Rhinefield, for Lieut. Munro; Hoddam Castle, Ecclefechan; Felstead Schools; Clatford Mills, Andover, for Mr. Forster; Adhurst St. Mary, for Mr. Bonham Carter; Shendish, for Mr. Longman; Leonardslee, Horsham, for Sir E. G. Loder; Ardoe, for Mr. Ogston; The Lodge, for Mr. de la Rue, etc. A number of houses have been wired for the supply from a central station, and the firm are carrying out work for the London County Council at the weights and measures testing station, Newington. The wiring of the Royal Colonial Institute has also been carried out by them. The Cardew patents have been further developed, and the earthing device has been formally approved and sealed by the Board of Trade. There is a considerable demand for the D.P. battery, both from the trade and private users.

J. K. FAHIE AND SON, of Dublin, have been fairly busy during the year, especially in the capacity of consulting electrical engineers. Numerous inspections of suitable water power in the country districts for driving dynamos have been made, and various reports prepared. The firm have now under their superintendence several installations, the most important carried out during the year being that of the suburban residence of the well-known Southern brewer, J. J. Murphy, Esq., J.P., on the banks of the Lee. The firm expect to have a good share of electrical work on hand during the present year.

CROMPTON-HOWELL ELECTRICAL STORAGE CO.—We give the contribution of this company to the year's information *re* work done in their own words: "As so much has been said about the inevitable losses which the use of accumulator storage entails on an electric supply system, we think this is a fitting opportunity to enclose the annual report we have just received from the engineer of the Kensington and Knightsbridge Company, which has been our oldest customer, and has continuously used our accumulators for nearly seven years. We give you the figures exactly as received, although they show a low efficiency during last January and February, due to the fact that owing to the exceptionally severe weather the temperature was so low that they were working in an exceptionally unfavourable manner. As soon as means were provided for maintaining the battery-rooms at a regular temperature, the efficiency at once rose to the average of the year—viz., about 79 per cent. These efficiencies are the actual commercial efficiencies taken at the recording meters. The losses include not only the losses in the batteries themselves, but those due to the resistance of the charging leads, which connect the distant accumulator station with the generating station. The losses shown, therefore, are accurately representative of the total losses due to the use of accumulators for that part of the output which passes through them.

REMARKS.—During January no provision had been made at the Queen's Gate battery station for heating so that the efficiency fell very low. During March improvements were made in the system of charging the batteries, hence the increased efficiency. The efficiency in watts cannot be calculated directly from the figures given for ampere-hours, as the results depend upon the proportion of work done by the batteries at each station. Owing to the fall of potential in the charging mains to Queen's Gate, the watt efficiency at that station must be lower than at Kensington Court; also it depends on the amount of charging done separately or in connection with the lighting. A few readings are given showing the efficiency of the Kensington Court home battery taken by themselves, in order to show how considerably the loss in the charging mains reduces the total average efficiency for the year.

This at Kensington is one-eighth part of the whole output, so that the use of accumulators in this station during the past year has only entailed the loss of 2½ per cent. in the entire output. Mr. Miller's remarks are interesting in showing that the efficiency obtained from the home batteries, which does not include losses in charging mains, is practically in excess of 85 per cent."

CRYSTAL PALACE DISTRICT ELECTRIC SUPPLY COMPANY.—The business of this company has been entirely reorganised during the last year. The principal works with which the company was connected were the provisional orders for the Crystal Palace and district, and for the city of Oxford; also the small central station in Walbrook. All business, except that connected with the Crystal Palace and district, was transferred, the name of the company having been altered to that of the Crystal Palace District Electric Supply Company, Limited, carrying on solely the business under

the provisional order for that locality. The provisional order for Oxford is being carried out by a local company entitled the Oxford Electric Company, Limited, who have contracted with the Electric Construction Corporation for a complete plant comprising central station for the supply of a continuous current of moderate high tension, with subsidiary transformer and accumulator stations, and an application is now before the Board of Trade for the transfer of the provisional order to the local company in question. The Walbrook station has been transferred to the Electric Construction Corporation. The generating station at Sydenham is ready for the supply of current to the exhibitors at the Crystal Palace. The works have been carried out with extraordinary energy by Messrs. J. E. H. Gordon and Co., whose contract was signed on the 13th August last, and the works are now practically completed, as already described in this journal. A large number of the exhibitors at the Crystal Palace have contracted with the company for the supply of current, including, among others, the following: Edison-Swan United, Wm. S. Freeman, Shirley and Co., James Pitkin, the Mining and General Electric Lamp Company, Woodhouse and Rawson United, the Medical Battery Company, the Electric Construction Corporation, Consolidated Telephone Constiuction, and Maintenance Company, Thomas Jenner, Rashleigh Phipps and Dawson, the Fowler-Waring Cables Company, Swinburne and Co., Frank Suter and Co., Marryat, Lillywhite, and Co., the Electrical Power Storage Company, the Telegraph Manufacturing Company, Evered and Co., Anders Elliott and Chetham-Strode, the Western Electric Company, etc. At Oxford the building of the generating station at Cannon Wharf, on the banks of the River Thames, and which will occupy 100ft. frontage to the river, is being rapidly pushed forward, and it is expected that the supply of electricity will be ready early in the spring. The demand in Oxford promises to be very large, as the project has been very favourably received by the heads of colleges and public institutions, the Corporation, private residents, traders, etc.

The General Electric Company can again report considerable expansion in their works at Manchester during the year 1891. They have taken three more buildings, and increased the number of hands from about 400 to nearly 600. The demand for electric light fittings, such as switchboards, switches, cut-outs, ceiling roses, lampholders, has been very large, and at the beginning of the winter stocks were thoroughly exhausted, and the company had to make great efforts to cope with the demand. They have largely increased the factory for making meters, both current and volt or ammeters, and the facilities for calibrating and testing are now such that they can fill any orders at early dates. It was natural that the department for electric signalling should be increased considerably during the last year, as then the telephone patents expired, and immediately after the expiry the company was extremely busy and full with orders for transmitters, receivers, and all kinds of switches. The Johnson microphone, of which they are the sole makers, has especially taken extremely quickly, and has found its way already into several large and important central stations. As for the general supply business, the home trade has been increasing very considerably during the year, both in London and most of the country towns, but it is unfortunately found that the prices are being cut down in all articles, leaving a margin of profit which seems ridiculous, considering the newness and risks of the electrical trade, which leaves only one consolation—that it is impossible to continue. The trade to the Continent and to the Colonies, however, has not only increased in volume, but has also been more profitable, and the company finds that some of the most outlandish and uncivilised countries are becoming their best customers. The endeavour for the new year is to again improve all china fittings to a degree of perfection to which they have never attained, and to keep large stocks in advance so that contractors may draw from stocks in future without the expense and risk of keeping stock for themselves.

General Electric Power and Traction Company.—The close of 1891 sees the end of the first financial year of this company. It will be gathered from the directors' report, which was published on the 18th of December, that electric traction has been almost entirely stopped by legislative and local obstacles of so stringent a character as to practically prohibit business; in spite of this, however, considerable progress has been made. The service of electric cars at Barking has been improved, and advantage has been taken of the experience there gained in estimating for maintenance contracts on a large and commercial scale. Indeed, as was foreshadowed by the chairman's speech to the shareholders, the company have reason to expect traction orders to the extent of £150,000 during the coming year. With the knowledge they have gained there is but little doubt of a satisfactory result. The sub-contract with the E.P.S. Company for the maintenance of the accumulators at a fixed mileage rate removes the only doubt which capitalists may have had for the success of this form of electric traction, for it is needless to say that the combined companies, with their unrivalled opportunities of gaining experience, are quite capable of carrying out contracts entrusted to them. Apart from Barking, considerable progress has been made in other places. For some months a self-contained car was run over the tramway system at Liverpool, carrying ordinary loads and keeping schedule time, thus proving the practicability of this class of car over steep grades. A smaller accumulator car is now being built for use on the Birmingham lines, so as to make comparison with the cost of the larger double-bogie trams running there at present. It is firmly believed by the company that these small accumulator cars, carrying about 36 passengers, will satisfactorily solve the problem of tramcar propulsion in our crowded thoroughfares. In mining work the company has been very busy, and has fully doubled the quantity of work done in this department in the preceding year. Electricity has been used for lighting, pumping, hauling, fan driving, and coal-getting with unvarying success. In launch work the company stands practically alone, and during the busy periods of last season controlled the pleasure traffic of the Thames. During week-ends the whole of their available boats were usually let, and in some cases could have been let two or three times over. In spite of the bad season this department has been a distinct success, and should the weather be at all favourable next year a very handsome dividend may be evidently looked forward to from this department. Viewing the rapid extension of launch work, the company have acquired land near Chertsey, and are now building hulls for their clients and for future extensions of the Thames fleet. During the Naval Exhibition a special feature was made of this branch of the company's business, and an electric pinnace of the man-of-war type was shown equipped ready

for slinging in davits. This led to some important business with foreign Governments, and three sea-going boats, 50ft. in length, were dispatched to Russia. On Lake Windermere the company's launches were usefully employed during the whole of the season, and derived their power for charging solely from a turbine, the first instance of the kind known when water power was used for charging boat accumulators. Arrangements have been concluded with the Manchester Ship Canal Syndicate by which a fleet of electric launches will run on part of the Ship Canal early in the spring. The company are about to erect an extensive electric copper-refining plant on the bank of the Thames, which they hope to have in full operation about April next. The company have given considerable attention to electric lighting both in London and the provinces, and have had a very satisfactory amount of work for this department. The sale of dynamos and motors for general purposes has largely increased, and the company are confidently looking forward to a further extension of the motor trade, with both direct and alternating current, as the use of electricity from central stations becomes more largely adopted.

Ernest Scott and Mountain, Close Works, Newcastle-on-Tyne, have been extremely busy during the whole of the past year in their electrical department, which has very largely developed since the firm commenced the manufacture of electrical machinery and the supplying of electric light installations. During the year the firm have supplied for their various installations and to trade customers at home and abroad over 150 dynamos of various sizes, most of them being of large size, and amongst the important installations which they have supplied are the following: The large flour mills at Dunston-on-Tyne, which have recently been erected by the Co-operative Wholesale Society, have been lighted throughout by electricity, the installation consisting of two Tyne compound-wound dynamos, each capable of running as a maximum 600 16-c.p. lamps, one Tyne compound-wound dynamo capable of running 15 2,000-c.p. arc lamps, and one Tyne compound-wound dynamo for the pilot installation capable of running 100 16-c.p. lamps. Throughout the mill there are installed about 600 16-c.p. lamps, this being the largest electric light installation in any flour mill in the United Kingdom. Since the starting of the installation in February the plant has run without the slightest hitch of any kind, and has given great satisfaction to the society. Messrs. Arthur and Co.'s factory, at Anderston, Glasgow, has also been lighted by the same firm, this installation consisting of two Tyne compound-wound dynamos capable of running 600 16-c.p. lamps each, and 700 lamps and fittings fixed throughout their new works. Messrs. Jones Bros. and Co.'s mills at Leigh and Bedford, near Manchester, have also been lighted. This installation consists of two 600-light Tyne compound-wound dynamos and 800 16-c.p. lamps. The firm have lighted several frozen meat stores in England and abroad; amongst these may be mentioned Messrs. J. Nelson and Sons' stores at Bristol, the Northern Counties Ice Company's stores, Newcastle-on-Tyne, and a large cold meat store in Brazil. Amongst smaller installations that the firm have carried out is the lighting of Messrs. H. S. Edwards and Sons' dry docks at North Shields; this installation was specially designed to suit the firm's requirements, and has been arranged so that petroleum oil steamers can be repaired by means of the light, the lamps being lowered into the holds by means of flexible cables strongly armoured. For Messrs. Edwards's Shipbuilding Company several electric light installations have been supplied for steamers, all of these having given great satisfaction. An installation has also just been completed for the Armagh Spinning Company, Armagh, Ireland, this installation consisting of one 400-light dynamo and 400 lamps and fittings, and has given the Armagh Company every satisfaction; in fact, they are anticipating a considerable extension amongst their other mills. Amongst other work in hand, the firm advise us that they are lighting the Fustian Machine Cutting Company's mills in Manchester, this company having been formed to cut velvet by machinery, instead of by hand as previously. The electric light installation will consist of two 40-unit dynamos, each capable of running 650 16-c.p. lamps, and a pilot dynamo to run 100 16-c.p. lamps, about 1,000 incandescent lamps and fittings being installed throughout the mill. Lord Ellesmere has also placed his contract with the firm for the lighting of a large private house and training establishment he is building at Newmarket. A large installation for Mr. Walter Jones, Cheshire, for the lighting of his private house is just upon completion, and a large installation for the Bolton Technical School will be completed early next year. The contract was placed with Messrs. Ernest Scott and Mountain, Limited, for the technical school chiefly on account of the great success of their installation at the *Bolton Evening News* Printing Works, the latter installation having been completed early in the year. The firm inform us that they have supplied a large number of dynamos and complete installations for South Africa, where they have an established office, and they anticipate doing a large business in the future with this country as things improve. The firm inform us that they are now bringing out several new designs of electrical pumping and mining plant for which there will undoubtedly be a very large demand in this district, and they expect to settle several important contracts for this description of machinery. Amongst private local installations completed during the past year may be mentioned the lighting of the Union Club, and, amongst others, the private houses of Messrs. B. J. Sutherland, R. H. Haggie, W. Sharp, C. D. Hill, J. Cameron Swan, C. M. Forster, R. B. Duncan. Installations have also been completed for G. and J. Stubley, Batley; S. Knowles and Co., Bury; Henderson and Co., Durham; Paterson, Elder, and Co.; and Crann and Co., Leith; Scott and Co., Greenock; Broadbent and Sons, Shires and Co., Slaithwaite Spinning Company, Wood, Sons, and North, Vickerman and Co., Rayner and Co., Huddersfield; Amos and Smith, Hull; Hutchinson and Co., Kirkcaldy; Hennochsberg and Ellis, Liverpool; Manchester Ship Canal, Baxendale and Co., Manchester; Rossendale and Co., Rawtenstall; Fairbrother and Co., Sheffield; A. and J. Macnab, Edinburgh; River Wear Commissioners, Sunderland; Arnold, Perrett, and Co., Gloucester; and the Argentine Meat Company, Brazil.

Newton Electrical Engineering Works.—This firm commenced business in 1890. The business has increased very rapidly, and as the firm lays itself out to work for the trade, the rapid increase has necessitated the building of much larger works. During the past year orders for automatic switches and transformers have come freely to hand. An order has just been received for a high-pressure continuous-current plant, consisting of generator and transformer, to go to Italy. Among other work, installations of lighting plant have been

executed for Major R. G. Godson, Westwood Park, Droitwich; Rev. G. E. Hermon, Doublebois House, Doublebois, Cornwall; and in the factories of Messrs. Candy and Co., Heathfield; Mr. J. A. Sherrin, Weymouth; and Messrs. Simpson, Strickland, and Co., Dartmouth. Mr. Newton was, if we remember rightly, an exhibitor at the Bath and West of England Show, and is one at the Crystal Palace Exhibition.

RANSOMES, SIMS, AND JEFFERIES.—During the past year Messrs. Ransomes, Sims, and Jefferies, Limited, of Ipswich, have been very busy in supplying motors for electric light plants, many of which have been for installations in Great Britain, France, Spain, Germany, etc., as also for Australia, India, and the East.

JOINT-STOCK COMPANIES WOUND UP IN 1891.—The following is a list of electrical companies which were wound up during last year:

VOLUNTARILY WOUND UP.

Jan. 1.—Woodhouse and Rawson Electric Manufacturing Company.
Feb. 13.—Cadogan Electric Light Company.
Mar. 16.—The South of England Telephone Company.
Mar. 20. -Woodhouse and Rawson Electric Supply Company of Great Britain.
April 17.—Electro-Metallurgical Company.
April 22.—Simplex Electrical Syndicate.
April 23.—Electrical Engineering Corporation.
July 3.—Corinthian Electro-Medical Battery Company.
Sept. 15.—Institute of Medical Electricity.
Sept. 30.—City of London Electric Lighting (Pioneer) Company.

The winding up of the Cadogan Electric Light Company, begun voluntarily, was ordered to be continued under the supervision of the Court.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

THE TAXATION OF MACHINERY.

SIR,—My committee, in conjunction with a large number of public and representative bodies, have arranged to hold a conference to consider the terms of the Bill proposed to be introduced into the House of Commons in the ensuing session to declare the law as to this question, and the Council of the Manchester Chamber of Commerce have kindly granted the use of their board-room on the 26th January for the purpose.

If those of your readers who desire the success of this Bill will communicate with me, I will forward them a draft of the proposed Bill and any further information required.

The attendance is particularly desired of delegates from the associations representing the various interests of users of machinery.—Yours, etc.,

G. HUMPHREYS DAVIES, Secretary.

National Society for the Exemption of Machinery from Rating, 8, Laurence Pountney-hill, E. C., Jan. 5, 1892.

NOTE ON INTERFERENCE WITH ALTERNATING CURRENTS.

SIR,—In the abstract of my paper before the Physical Society on the 18th ult., printed in your last number, there is an error I should like to correct.

It is stated with regard to the experiment described—on the 100-kilowatt alternator, three-quarter mile of concentric cable, and 18-kilowatt transformer—that switching on the concentric cable produced the same rise of pressure at the alternator terminals whether the transformer at the far end of the cable was loaded or not. The facts of the case are as follows: The same rise of pressure was observed at the alternator terminals on switching on the cable, whether the transformer at the far end was connected to the cable or not, when the transformer secondary was open or loaded only with about a dozen 60-watt lamps (a very small load for an 18-kilowatt transformer).—Yours, etc.,

HAMILTON KILGOUR.

January 7th, 1892.

ELECTRIC LIGHT DECORATIVE FITTINGS.

BY SYDNEY F. WALKER.

Mrs. J. E. H. Gordon has done good service by her article in the *Fortnightly Review* a short time since dealing with this subject.

Decoration is essentially the province of the artist, and every lady is, or should be, an artist in her own home. Now, too, that it may fairly be claimed that electric house lighting has come to stay, and that town after town is laying down plant, tearing up its streets, and preparing a hearty welcome for the new illuminant, surely it is time that a new departure was made in the matter of the decorations which form part of the fittings that carry the lights, whatever they may be. Has not the time arrived when the electrical engineer and the artist should collaborate, to produce something different from the stiff gas pendants and brackets that have pained our eyes for so long?

Of course there is still a good deal to be said for the old forms of fittings, with their more or less concealed pipes, and their ugly burners. As long as gas was the illuminant, and gas-pipes were necessary, they must be worked into the fittings of gas brackets and pendants. You might have flying Cupids, or Grecian statuary, but you must have a pipe concealed inside them, and the pipe must be visible, in some form or other, where the outlet for the gas was placed. Usually, too, the gas flame required shading, and the globe that was used for the purpose must be supported in some way.

As the gas burnt best, or at least gave the best light, when escaping upwards, nearly all gas-fittings were so arranged that the burners provided for the egress of the gas, were pointing in a vertical direction.

The early types of electroliers naturally took the form of gas chandeliers and gas brackets, but with the burners turned downwards. Now the question arises, can all this be changed? It is no longer necessary that the burner shall point in any particular direction. The burner itself is light, and therefore does not require the massive apparatus for its support that are often found in use with large gas chandeliers. Can the pipes be dispensed with, or is it wise to retain them in all their hideousness as a protection for the wires that are passed through them?

It is certainly convenient to conceal the wires inside the tubes of a chandelier, or electrolier, if the term be preferred; but it would be better to have no pipes and no chandeliers at all. Every time you thread a covered wire through a pipe, especially when it is curved, as most of them are, you run a great risk of damaging the insulation of your wire; and it therefore becomes necessary to pay for an increased cost of the wire to provide for this possibility, as well as to pay for the expensive electrolier which you no longer require. Flexible cords, well insulated in the process of manufacture, run less risk of damage to their insulation, and of consequent short circuits, when hanging freely in air than when confined in a tube.

If this is correct, then the whole of our electric lighting arrangements require remodelling.

But there is another point in which domestic lighting by means of electricity differs very much from that by means of gas. With the latter, except for street lighting, only one power could be obtained from any single burner, unless special arrangements were made, so that increased light was always obtained by grouping a number of these burners together in one chandelier, which was generally placed in the centre of the room. Of late years, under the pressure of the probable competition of the new illuminant, something has been done in the matter of distributing gas burners round the walls of the room to be lighted; but even now, in large halls, illumination is usually by means of a huge cluster of burners near the centre, supported by a few smaller clusters in other parts. The brackets placed round the rooms of private houses, too, perhaps do not appear very ugly to us, because we are accustomed to them,

but viewed with other decorations they are certainly not picturesque.

With electricity, we are under no obligation to multiply our lamps. If we require the light of more than one in any particular place, we may have the light given by two lamps, or a hundred if we wish, concentrated in one lamp, requiring only one set of fittings. Or we may have the light distributed about the room, on its walls, or suspended from the ceiling at various points, without the necessity of destroying any artistic effect that may have been designed.

Should not, therefore, a new line be struck out in this matter, gradually absorbing the full adaptability of the electric light to its surroundings? Gas-burners are in the room, but they and their supports are rarely of the room—they are excrescences. May not electric lamps be arranged to be of the room, to form part of its decorations, whether the room be devoted to eating, to lounging, or to gossip? But there is another point that should be noticed, and that is, placing the lamps where they can be of most service. With gas this is often a difficult matter, owing to the necessity of providing for the harmless combustion of the illuminant. With electricity this necessity does not exist.

Mrs. Gordon gives a useful hint, amongst others, that the lamp should not be placed so that it is reflected in a mirror right into the eyes of whoever may be in front of it. With gas it has often been very difficult to avoid this; in fact, candles by the side of a dressing-table or cheval-glass are almost a necessity where gas is employed. With the electric light it should be a simple matter to accomplish the usually awkward operation of viewing one's back hair—a point that most men will not trouble about, and that designers of electric light fittings may be excused if they do not fully appreciate, but which is of great importance to ladies. Then what form shall the new style of decorations take? Already something has been done in the right direction. Lamps are shaded by leaves moulded in thin metal of various hues, and are made to peep out of shells and so on. But here again, the lamps are in the leaves but not of them. The leaves are in the room but not of the room. Leaves that could spring from no living tree, and that appear to grow out of a brass tube, or from nothing, are hardly artistic in the real sense of the term. Why should not the lining, shall it be called, of a lady's boudoir be composed of the spreading branches of a tree, and the lamps either be the fruit of the tree in shape and colour, or be concealed by its leaves? How deliciously cool and soft to the eyes such an arrangement would be. English plants offer numbers of subjects which, properly worked up, would lend themselves to this idea; and in tropical plants would be found more than every artist of every nation could possibly utilise for centuries.

But the artist is by no means confined to the vegetable world for subjects that will help him in this matter. The animal world, in its various forms, offers an abundance. What could be prettier, for instance, for a staircase light than a kitten seated on the lower balustrade playing with a ball, the ball being the lamp and the kitten one of those wonderful creations in china that are to be seen in the potteries. Classical and historical subjects also would lend themselves very readily to the same object. For a corner light, for instance, or for some nook in a cosy drawing-room, such a group as that of Eve and the serpent, with our common mother in the act of plucking the forbidden fruit, the fruit, of course, being the lamp, would be far chaster than anything to be seen in any drawing-room at the present day. Remembering, too, that the lamp may take any form, it being merely a question of manufacture to arrange the details, such a group as the death of Cæsar at the hand of Brutus, the lamp in this case being the dagger; the death of Harold at the Battle of Hastings, the lamp being the arrow, and numerous others, would well adorn a library or a study. Flying Cupids would come in well in certain cases, but they should be of china, and should either form the lamps themselves, or be semi-transparent shades for the lamps.

Doubtless the whole of the above sounds revolutionary, but surely electricity is nothing if not revolutionary. It is the mission of the youngest of the sciences to ease the lot of mankind, and to beautify the world, and every home in the world.

NEW SOUTH WALES ELECTRICAL CLUB.

INAUGURAL ADDRESS.

A meeting of the above society was held at the rooms of the Engineering Association of New South Wales on Thursday evening, the 12th November, 1891. After the usual preliminary business, the president, Mr. E. C. Cracknell, delivered his inaugural address as follows:

As I have no doubt nearly all of you have read the early history and progress of magnetism and electricity, I propose only to deal with the early discoveries, the inventions, which were the outcome of these discoveries, and the developments which have resulted from both, for the comfort and enjoyment of the present generation. Little did the early *savants* know what their energy and zeal in the cause of science, when they were toiling with their slender means and more slender resources, would bring about for the benefit of mankind. The names of these illustrious pioneers I shall allude to from time to time during this address, and I am sure you will endorse every sentiment as well-merited praise for their exertion and, in most instances, poorly-requited labours. You will find that the world is indebted to the Chinese not only for the discovery, but for utilising the magnet. It is stated in Chinese history that 2,637 years B.C. Hoang-ti constructed a chariot upon which stood a prominent female figure which indicated the four cardinal points, which always turned to the south, no matter the direction taken by the chariot, by which means he succeeded in capturing the rebellious Prince Techi-yeou, the Emperor's troops who were pursuing the Prince having lost their way through heavy fogs on the plains of Tchou-tou, in Tartary. This, no doubt, was the first discovery of the magnetic needle, or mariner's compass. The Greeks also took credit that 1,000 years B.C. a Greek shepherd observed the attractive power of the loadstone at Magnesia, in Lydia, his metallic crook having been attracted by a rock now known as native loadstone. Shakespeare says in "Midsummer Night's Dream," "You draw me, you hard-hearted adamant, and yet you draw not iron, for my head is true as steel." Agamemnon, B.C. 1084, employed a line of optical signals to advise his Queen of the fall of Troy. So far I have merely alluded to the discovery of magnetism in the early days and its application by the ancients, but I must now refer to the first observation made by Thales, of Miletus, that electricity was very strongly developed by friction in amber, which very soon after astonished the Romans as well as the Greeks by its attractive power over light bodies, such as paper, straw, and leaves, in the same way as the magnet attracts iron. As lightning existed long before any of the dates mentioned, it would not be fair to exclude such a powerful and subtle agent from a passing remark. It has been stated that the Temple of Jerusalem was never struck by lightning during a thousand years, for the simple reason that a forest of golden points covered its roof, and that the roof was connected with the caverns in an adjacent hill, in consequence of which the points would act as conductors. This might be a new idea for Prof. Oliver Lodge, who would find that his bird-cage protection to buildings from lightning was as old as Moses, who was born 1,570 years B.C. A passing allusion to ancient medical treatment in a primitive way by electricity may not be out of place. In the year A.D. 20 it is recorded that a freedman of Tiberius was cured of gout by shocks received from the electric eel, and Fahie states that along the banks of the Calabar River, in Africa, the natives employed the electrical properties of the gymnotus for the cure of their sick children. Yet it is within the recollection of most of us that the whole medical profession, backed up by their leading journals, scouted electricity as a curative agent, as quackery amounting to fraud. How very different are their opinions at the present day, since there is no medical man amongst us who would dare to tell his patients that he does not believe in electricity as a curative agent? But to continue these early discoveries. Gore tells us that the Romans, A.D. 410, were acquainted with electric separation of metals—that is, that metals acquire a coat of copper on being immersed in a copper solution. That most interesting little experiment known to us as "De la Rive's battery" appears to date back as far as A.D. 425, the only difference being that a magnetic needle was attached to a piece of cork floating in a vessel of water, which Bishop Severus found would direct its polarity by placing a magnet under a thick wooden table upon which the vessel was placed. As late as 1260 Brunetto Latini speaks of the mariner's compass as likely to be useful at sea; but he adds, "No master mariner dares to use it, lest he should fall under the supposition that he is a magician, nor would sailors venture to sea under his command if he carried with him such an instrument." It was not until 1269 that the variation, or the declination, of the compass was understood. Marco Polo was evidently aware of the compass, as during his voyage of discovery when he set out from Acre, in 1271, and returned to Venice, in 1295, he was provided with and understood the use of the magnetic needle, as on his journey South he left the North Star out of sight, which in

northern latitudes was previous to this time considered the mariners' guiding star. We have been for many years under the impression that Oersted was the first to give us the foundation for the needle telegraph, but Mr. Mottelay, in his "Chronological History of Electricity, Galvanism, Magnetism, etc.," has turned up from the "Encyclopædia Britannica," under an article on "Optics," by Prof. Stanley Jevons, that as far back as A.D. 426 in "Speculum Lapadium" there is the following allusion: "I do not fear; with a long-absent friend, even though he be confined in prison walls, we can communicate what we wish by means of two compass needles circumscribed with an alphabet." In the reign of Queen Elizabeth it appears that our own countryman, Dr. Gilberte, of Colchester, physician to the Queen, published a great work for that date, in which he enumerates all the substances which are susceptible to electrical excitation, and makes use of the words electric force, electric connection, and electric attraction. Now we make a jump of about 60 years, and find that Otto Van Guericke, of Magdeburg, was the first to construct a practical electrical machine, consisting of a globe of sulphur cast in a glass sphere, which, when excited by its being revolved against a rubber, emitted both sound and light. In 1720, to Stephen Grey, a pensioner in the Charterhouse, is attributed the first discovery of the principles of electric conduction, and its insulation, as well as to the fact, but not to the principle, of induction. Thus to Grey is due the credit of having laid the foundation of electricity as a science. In 1729, Grey and Wheeler succeeded in transmitting electricity through packthread, supported by silken cords, a distance of 765ft., and through wires a distance of 886ft. To Dufoy, in 1733, is due the discovery of two kinds of electricity—viz., known as the phenomenon of attraction and repulsion. Dufoy says there are two kinds of electricity very different from one another—vitreous or positive, and the other resinous or negative. The first is that of glass, rock, precious stones, etc., and the other that of amber, copal, gum lac, silk, thread, paper, and other substances; thus those which are vitreous repel all those that are vitreous, and attract all those that are resinous. Dufoy also observed that by repeating Grey's experiment, by wetting the packthread he was enabled to convey a current through 1,256ft. instead of 675ft. when dry. In 1746, the discovery of the Leyden jar was made. But it appears rather doubtful whether, from an experiment made a year earlier at Dantzic, that the latter place should not be credited with the invention; but Sir William Watson, the English scientist, is entitled to the credit of the double coating of the jar, as well as the plus and minus of electricity. In the same year the first glass-plate and cylinder machines were constructed. The next work in the early history of electricity was Franklin's famous kite experiment, in 1752, in which he proved that the lightning's flash was identical with the spark from a Leyden jar. Galvani's classical experiment with the frog's leg, in 1786, closely followed, in 1800, by Volta's publication at the Royal Institution of his discovery of the voltaic battery, formed on a basis on which was founded Oersted's important discovery, in 1819, of the effect produced on a suspended magnet by an adjacent current wire. Ampère's theory of electric dynamics, Schweigger's invention of the galvanometer, and Seebeck's discovery of thermo-electric currents, 1822; Ohm's law, laid down, in 1827, and Arago's publication of his researches on the rotary effect of adjacent current-carrying conductors, culminated in the magnificent researches and improvements of Humphry Davy, and that truly great man Michael Faraday, who in 1832 discovered the principle of electromagnetic induction, and who has laid down for us the law of electrostatics, induction, electrolysis, and diamagnetism, and whose book on "Experimental Research" is still a mine of wealth for the inventor, and is only equalled in value by the works of James Clerk Maxwell, of the value of which we are comparatively still ignorant, and in which many a clever man has found his own discoveries clearly laid down, and worked out mathematically many years previously by this wonderful man. From this era electrical history may be said to have ended and electrical science to have commenced, and I propose now to go more deeply into the development of these branches of the latter which are now in ordinary commercial and domestic use. I will now ask you to follow me in a rapid glance at the development of electricity as applied to telegraphy. In Holy Writ we have a prophetic allusion to the telegraph in the thirty-eighth chapter of Job, "Canst thou send lightnings that they may go and say unto thee 'Here we are.'" In the family the electric telegraph has become a "household word," bringing absent members into sympathetic contact of heart and mind in the same instant of time. Of commerce it has become the very life-blood; it has gathered the civilised world together into instant and direct intercourse; a network of sympathetic intelligence encircles the earth, and we feel it difficult to imagine it had not always existed. Imagine it removed! There is an ebb of centuries in the life of civilisation, and yet it is but little more than 50 years since the first practical telegraph commenced to work. The names of those who have from time to time essayed to solve the problem of conveying information by means of electricity are almost legion. Philosophers from very early days had tried, and some met with a certain measure of success. Amongst others in 1786, Sir William Watson passed electricity through 9,000ft. of earth and water across the Thames, and through 18,000ft. of wire suspended upon poles, at Shooter's Hill. In the following year Franklin repeated like experiments at Philadelphia. In 1774, Lesage, at Geneva, reduced to practice a plan of telegraphing by static electricity and pith balls, using 24 wires, one for each letter of the alphabet. Lomond, in 1786, combined the signals of the pith balls so as to diminish the number of wires, and in 1794 Betancourt worked a pith-ball telegraph from Madrid to Aranjuez. In the same year Reusser proposed to make the elecric spark illuminate a letter formed of separate pieces of tinfoil placed in the path of the discharge, using a separate wire for each letter. We are now come to the present century, when, in 1816, Ronalds worked his system of pith balls and dials through eight miles of wire at Hammersmith. This was the first and last successful application of static electricity to a telegraph. In 1830 Schelling invented his telegraph with five needles, which up to that time was the most perfect plan of a telegraph yet produced, and in 1835 he reduced it to a single-needle arrangement, and exhibited the system at Bonn. The history of the subject so far shows us that no single individual can lay claim to the distinction of being the inventor of the electric telegraph; 1837 is the year of the first practical electric telegraph, and it remained for Cooke and Wheatstone in that year to first demonstrate the practicability of telegraphy being worked on a commercial basis. It was once a popular fallacy in England and elsewhere, that Cooke and Wheatstone were the original inventors of the electric telegraph. It will be seen, however, that the telegraph grew up little by little, each inventor adding his little to advance it towards perfection. Messrs. Cooke and Wheatstone were the first to establish a telegraph for practical purposes on a comparatively large scale, and in which the public were more nearly concerned than in those experiments in which the ends of wires were brought into laboratories and observatories. Morse and Steinheil have also been thought by many to be the fathers of the telegraph, but whilst in 1837 a line had been built and was in working order between London and Slough, it was not until 1844 that the first wire was built from Washington to Baltimore, and a message, dictated by a Miss Ebsworth—which is still preserved in the Hartford Museum—announced the existence of a practical telegraph on the American continent. Wheatstone's first instruments had five needles, and as many lines were required between each station to work the system. It was, however, rapidly improved upon, and the number of needles reduced to two and then to one. A return wire was, however, required to complete the circuit. It is to Steinheil that we are indebted for the discovery that the earth could be utilised for the return circuit, a discovery which was of the greatest service in further developing telegraphy. Bain, the inventor of the chemical telegraph, also independently discovered the principle somewhat later. From this time the strides made in the science were marvellous. In America, England, and the whole of Europe, inventors were busy at work, and almost every year saw improvements and new systems brought into use. To enumerate the different systems would comprise an extensive catalogue, and it would take up too much of our time to trace the electric telegraph through its many subsequent stages of development. Printing, automatic, chemical, harmonic, sound, and visual telegraphs followed each other in bewildering confusion, each and all equally well adapted for the special purpose for which they were designed. Indeed, perhaps in no other invention of modern times have so many different methods been devised to obtain the same result, the amount of ingenuity displayed by the different inventors of the many systems of telegraphs, together with the manner in which well-known scientific laws have been brought to bear in their construction, will render the electric telegraph one of the greatest monuments of the inventive genius of the present century. Like most other branches of electrical science, telegraphy even now can hardly be considered to be much more than in its infancy. When it is remembered that a little more than 50 years ago telegraphy was merely a scientific toy requiring many wires to transmit a single word, that the use of the earth as a return circuit was not made use of practically, it will be seen what strides have been made when one wire is now made to do the work of two, four, six, and even more; and when so much has been done in so comparatively short a time, one begins to think it quite within the bounds of possibility that the day will yet come when no wire at all will be required, but the earth itself will be made the means of communication from one end of the world to the other. The first line of telegraph in Australia was established in Victoria between Melbourne and Williamstown in the year 1854; in South Australia, between Adelaide and Port Adelaide and the Semaphore in the early part of 1856; in New South Wales, between Sydney and Liverpool, and Sydney and South Head in January, 1858. The first line opened for intercolonial traffic between Sydney and Melbourne was in November, 1858; these were speedily followed by lines Sydney

to Bathurst and Sydney to Newcastle; other lines soon became necessary, and now we have in this colony alone no less than 23,500 miles of line in actual work. (The progress made in the four principal colonies from 1860 to 1890 was demonstrated at this stage by a tabulated statement, which showed the length of line in use in each succeeding decade, the number of messages transmitted, and the revenue received. Some details of the amount of telegraphic business transacted in the United Kingdom, France, and New South Wales were also given in a form which admitted of ready comparison). I cannot pass from this portion of my subject without referring especially to the wonders of submarine telegraphy, and of the signal services rendered to that particular branch by both Wheatstone and Sir William Thomson. The greatest achievement of the electric telegraph is unquestionably the instantaneous transmission of intelligence across seas. The first cable of any length was laid in 1850 between Dover and Calais, but it only lasted one hour before breaking down. Several small cables were laid during the next few years with more or less success, until on August 5, 1858, the first Atlantic cable was successfully laid, and congratulatory messages were for the first time flashed from the Old to the New World. This cable was faulty when laid, and gradually got worse, till three weeks after its submersion it completely broke down. Sufficient success had, however, been achieved to warrant commercial men taking the matter up, and when this is the case the ultimate success of the undertaking may, I think, be generally looked upon as moderately secure, for these gentlemen usually require pretty good reasons before they "plank the dollar down," as our American friends would say. Several Atlantic cables followed, each showing a marked improvement both in electrical and mechanical construction, till at the present day 11 cables connect the American continent with Europe and England, and there is hardly a corner of the globe which is not in direct communication with the great centres of population. The earlier instruments used for the working of the cables, as you are no doubt aware, consisted of Thomson's reflecting galvanometer, the movement of the beam of light to the right or left of zero indicating the dot and dash of the Morse code; but very soon Sir William Thomson brought out his syphon recorder, by which means the signals were recorded on an endless tape in Morse characters. This instrument is alone a monument to its inventor and a marvel of ingenuity. But great as have been the wonders wrought by the telegraph, it remained for Bell to astound the world by announcing the advent of the telephone, for there is no doubt that to Bell must be credited the honour of first devising a telephone fitted for practical use. As far back as 1667 we find sound was transmitted to a distance by the aid of a wire or tight-drawn string, but it was not till 1877 that electrical reproduction of speeches was rendered practicable. Page's discovery of the emission of sounds by an electromagnet when subject to a rapid succession of currents, which was termed the "magnetic tick," led to further experimenting on the part of Boursel, De la Rive, and others, till in 1861 Philip Reis, of Fredrichsdorf, invented an apparatus which reproduced musical sounds, but was only able to convey speech to a very limited extent. Reis was well aware of the importance of his invention, which at the time was treated as toy, and on one occasion remarked "that he had shown to the world a road to a great discovery, but left it to others to follow it up." Bell's first telephone consisted of a stave harmonica fastened to the poles of a permanent magnet with an electromagnet placed in front. The expense of such an apparatus prevented Bell from developing and perfecting the idea. His second telephone was the next instrument brought out, and for which a patent was taken out early in 1876. About the same time Elisha Gray also requested a patent for his telephone. A dispute arose between Bell and Gray about the patent of the vibrating membrane, which was decided in favour of Bell. The third telephone of Bell's was the form exhibited at the Philadelphia Exhibition in 1876, and this was the instrument which so much astonished Sir W. Thomson when he first saw it. The first practical magnetic telephone was exhibited early in 1877 in Salem, Massachusetts, by Bell, when a speech delivered in Boston was heard by an audience in Salem. Before the telephone could be brought to the commercial importance that it at present enjoys there was still a problem to be solved, the solution of which was effected by Hughes's discovery of the microphone; for although the principle involved in the microphone had been announced years before by Du Moncel, Hughes was the first to systematical y investigate the subject, but Edison appears to have been the first to construct a carbon transmitter in 1878. The difference between Edison's carbon transmitters and Hughes's microphone, in its simple form, was very slight, the object of both being to amplify the currents. The effect of the discovery of the microphone upon telephony was incalculable, and in the same way as all the numerous magnetic telephones are, more or less, imitations of Bell's original telephone, so all carbon transmitters are modifications of Hughes's invention. The number of these imitations is legion; many of them are without practical value, whilst others have given in practice superior results to the inventor's apparatus by enabling the listener to hear the words more distinctly. I will not inflict you with anything like an enumeration of the many different patterns of telephones which have been offered to the public since Bell's first discovery, or attempt to describe even the more salient points of difference between them. The principle involved in one and all is the same. The theory of the telephone has given rise to much controversy, and it will probably continue to be an interesting subject for discussion. Several explanations have been given to account for the actions and reactions which take place between the diaphragms of the transmitter and receiver. Some hold that the currents developed in a Bell telephone are much too feeble to account for the effects produced in the diaphragms of the receiver, if these effects are to be attributed to attraction pure and simple, and that molecular disturbances in the mass of the bar bear an important part in causing the vibration in the diaphragm. Whether this be so, or whatever the cause of the action may be, the instrument remains marvellous in its simplicity and astounding in its results. One of the latest applications of the telephone is that in which it is used as a telegraph receiver—in Mr. Langdon Davies's system, and to which he has given the name of "The Phonophore." Unlike in principle as are telephone and the ordinary Morse systems of telegraphy, yet by means of this ingenious instrument Mr. Davies has devised a means whereby both the telephone and the Morse are worked simultaneously on the one wire. The arrangement is likely to be largely used, and this is another instance of the inventive genius of the age. With the introduction of the telephone a world of research has been opened up, of the existence of which we were previously unaware. Hughes's induction balance has applied the telephone to a field of investigation of which we have hitherto been ignorant. Does it not seem wonderful, for instance, that we should be able to detect internal flaws in the mass of an iron rail, or in the case of a steel shell? And yet by an ingenious application of Hughes's induction balance in an instrument to which has been given the name of the "Schiseophone," it is now possible to pick out, by the aid of the telephone, flaws in a mass of metal which defy detection by any other means. Another appliance which depends for its action upon the principle of the induction balance is Captain M'Evoy's torpedo detector. As its name implies, it is designed for use in searching for submarine mines in harbours and channels. One portion of the balance, enclosed in a metal sinker, is attached to a small cable which is in connection with the telephonic portion of the apparatus in a boat. The sinker is dragged along the bottom of the channel where mines are suspected to have been laid. No sound is audible until the sinker reaches the vicinity of a mine, when a buzzing noise is heard in the telephone, which gradually increases as the mine is approached, and is loudest when it is touched. Medical science has also made use of the balance, and, as you will well remember, such an instrument was used in the case of the late President Garfield, by Prof. Graham Bell, to discover the position of the bullet. It is not to be wondered at that an instrument of such marvellous sensitiveness as the telephone should have been made use of to enable the faintest pulsation of the heart, of the pulse, and the arteries to be heard, and even to detect the normal muscular sound, and the characteristic rumbling noise when contraction of the muscles take place. I cannot leave this portion of my subject without alluding to the phenomenal commercial development of the telephone that has taken place within the last few years. In the arrangement of a telephone exchange every minute detail has been carefully thought out and provided for, and the general public have little idea of the mechanism required to enable "Smith" to ring up and talk to "Jones." The distance limit of telephonic communication is gradually being extended. New York has spoken to Chicago over 1,000 miles of wire, and the recent connection of London to Paris brings to mind Proctor's prediction "that a whisper would ere long pass beneath the Atlantic Ocean which none of the waves would drown." We are still as far from this imaginary consummation, but a beginning has been made. The rapid development of the telephone since its discovery is unique in the annals of science; it shows the increasing importance of science for the progress of civilisation and the immense import of Prof. Graham Bell's discovery. Every day witnesses new experiments, new problems for the solution of which the telephone affords a means of investigation. But new difficulties also arise from its application, the most serious of which is the well-known induction trouble—a difficulty of so serious a nature as at one time to threaten the development of the system. This trouble has been to a certain extent overcome by different means, but not in an altogether satisfactory manner; and as the spread of cables and leads carrying powerful currents required for motive power and lighting purposes increases, so does the necessity for united action become more apparent, if the greatest amount of good is to be obtained from each and all of the different modern applications of electricity. The natural sequence to the discovery of an instrument enabling us to detect sounds otherwise inaudible, was an instrument to enable us to record those

sounds. Such an apparatus was supplied by Edison when, in 1877, he introduced the phonograph, which created considerable sensation at the time. I mention the phonograph because of its close relationship to the telephone, not that electricity is concerned in its action, except in so far as the motive power is concerned, but also because it proves that the oscillations of a tympanum, like the disc of a telephone, are capable of producing all the effects of sound. There are something like 8,000 of these instruments at present in use in America, and it has even reached the "penny-in-the-slot" stage of existence, when music, song, and speech may be laid on tap, and, like a "Joe Miller" jest-book, tell the latest as well as the oldest good story. We have now to turn our attention to a branch of electrical engineering which has been even more rapid in its development and more universal in its use than almost any other. I refer, of course, to electric lighting and the use of electricity as a motive power. In this, as in other branches, there are many claimants for the honour of having been the first to make electric lighting a commercial success, and in this also we must finally come to the conclusion that the whole edifice has been built up, each inventor and discoverer depending for his ultimate result upon an experiment performed by some earlier investigator. I think we may fairly consider Faraday's discovery in 1832 of the principle of electromagnetic induction as being the foundation of modern commercial electric lighting, followed so quickly in 1833 by Pixii's magneto machine, which again was rapidly improved upon by Clarke, whose machine is still in common use for medical coils. The next notable incident was the invention by Dr. Werner Siemens, in 1857, of the well-known "H" armature, which was constructed of this shape so that the coils might revolve in the most powerful part of the magnetic field—a considerable advance on the instruments of Pixii and Clarke, in which the coils merely moved in front of the poles of the magnet. Next we have Wilde's machine, in which a small auxiliary magneto machine was used to produce a current for the purpose of exciting the fixed magnets of a larger machine with electromagnets instead of permanent magnets. And finally, we come to the true dynamo-electric principle. Hjorth in 1854 took out a patent for a machine which was near in principle to the modern machine; in it he had both permanent magnets and electromagnets and one armature. About the end of the year 1866 and the beginning of 1867 we find three claimants for the invention of the modern dynamo. Mr. S. A. Varley, who filed his provisional specification on December 24, 1866; and in February, 1867, Dr. C. W. Siemens and Sir Charles Wheatstone both announced the discovery independently at the same meeting of the Royal Society. In 1860 a further advance was made by Dr. Pacinotti, of the University of Pisa, who invented the ring type of armature. Curiously enough, his original machine, which was invented as a motor, had electromagnets for field magnets; and in his description Pacinotti states that the machine may be used to generate a current by substituting permanent magnets for electromagnets for the field. It was not until 1871 that Gramme invented his well-known ring form of armature, which still is used, with slight modifications, in most modern dynamos, such as the Manchester, Crompton, Paterson and Cooper, Brush-Victoria, and Hochhausen. The drum armature, which with various modifications we see used in the Siemens, Edison, and Weston machines, was invented by Von Hefner-Alteneck in the following year. Having followed the discovery of the dynamo-electric machine, we must retrace our steps to the year 1810, when Davy showed an arc light at the Royal Institution, using a battery of some 2,000 cells for the purpose. From this time until the discovery of the dynamo but little development took place owing to the excessive cost of producing sufficient current by means of batteries. In 1857 Serrin, and in 1858 Foucault, produced arc lamps in which the adjustment of the carbons was brought about automatically; but no real advance appears to have been made until 1876, when the Jablochkoff candle was invented, and with the help of the dynamo came into fairly extensive use for a time, though in 1858 an arc light driven by a Holmes magneto machine was installed in the South Foreland, and in 1862 in the Dungeness lighthouses. The Jablochkoff candle was soon discarded for the self-regulating arc lamp, of which those in most extensive use at present are the Brockie-Pell and Thomson-Houston. Useful as the arc lamp is for lighting streets, open spaces, and large buildings, it is entirely unfit for general domestic illumination, and consequently the attention of many inventors was drawn to the necessity of what at that time was termed "the subdivision of the electric light." At a very early period it was perceived that for this purpose the most promising method was the heating to incandescence of a continuous conductor, and platinum, and similar metals having a high melting point, were the first substances to be experimented with. We find, in 1845, an American named Starr took out a patent for a carbon lamp sealed into the vacuum chamber of a barometer tube. Then, in 1848, W. E. Staite took out a patent for making electric lamps of iridium, shaped in a horseshoe form. Up to 1878 very little improvement was made. In that year Sawyer and Man made their first lamp of carbonised paper. Edison, who in the following year took out patents, not only for an incandescent lamp, but for a system of electric lighting, is generally credited with having made electric lighting commercially successful. But I think that you will agree with me that due credit should be given to the other investigators in the same line of research—such as Sawyer and Man, Swan, Maxim, and Lane Fox, more especially to Swan, and Sawyer and Man. In 1883 a great advance was made by Gaulard and Gibbs, in the invention of their high-tension alternate-current transformer, which enabled electricity to be transmitted to much greater distances than could ever be achieved by continuous currents, a notable instance of which is the present experiment of transmitting power from Lauffen to Frankfort, a distance of over 100 miles, by means of high-tension alternating currents. The transformer is a direct descendant of the induction coil as first used by Faraday, and afterwards improved by Rhumkorff. As in former cases, Gaulard and Gibb's transformer has received many improvements at the hands of such men as Mordey, Zipernowski, Ferranti, Kapp, and others. The first central station in London, known as the Grosvenor Gallery Station, used Gaulard and Gibbs's transformers in 1885, and was the forerunner of the now famous Deptford station, constructed to use a pressure of 10,000 volts. For another important discovery in connection with electrical engineering, we must go back again to Planté's discovery, in 1859, and Faure's subsequent improvement, in 1880, of the secondary battery. In 1888, there were in England but eight central stations, with a total of 27,000 incandescent lamps in use. At the end of 1890 there were 48 stations, with a total of about 530,000 incandescent lamps in use, and a total ultimate provision for over a million. In America we find a more widespread use of electricity as an illuminant, as at the end of 1888 we find some 204 towns using an aggregate of over 5,000 arc lamps and 250,000 incandescent; in January of the present year there were 1,674 central stations at work, with an aggregate of over a million incandescent and over 30,000 arc lamps in use. I do not see that we are going ahead quite so fast in either Great Britain, Europe, or Australia. Still another modern development is the use of electricity as a motive power. As far back as 1830 Prof. Negro, of Padua, constructed an electric motor, using permanent and electro magnets; Jacobi, in 1834, used an electromotor, consisting entirely of electromagnets, to propel a boat on the Neva; in 1835 Stratingh and Becker, of Gruningen, and Botto, of Turin, constructed primitive electric cars, and Thomas Davenport, of Brandon, U.S.A., built a small circular railway at Springfield, Massachusetts; and amongst these early pioneers we must also mention Davidson, a Scotchman, who in 1838 built an electric car weighing five tons, with which he obtained a speed of four miles an hour. Elias in 1842 constructed a motor, having a Pacinotti ring for its armature, and we find various forms of motors invented by Froment, Hjorth, Page, Farmer, and others, with very little commercial advance, until the invention of the dynamo and the discovery of its reversibility. The first successful experiment was made with the electric railway exhibited by Siemens at the Berlin Exhibition in 1879. In England there is the underground City and South London Railway; and several others, besides the extension from Stockwell to Clapham underground, and the Liverpool Overhead, and others in progress; also many on the Continent of Europe. The present period has been, I think, very properly termed the "electric age." Incandescent and arc lamps greet us at every turn; no business office is now complete without its telephone, the sending of telegrams or cablegrams is of no more import nowadays than posting a letter, electric bells are in every modern-built house, a ride on a car driven by electricity is no longer an event to be remembered, and we see and hear of electric motors being used for all manner of purposes in many different trades; for driving lathes, sewing machines, printing presses, fans, pumps, lawn-mowers, for blowing organs, heating railway carriages, for mining drills and coal-cutters, riveting machines, welding, and a host of other purposes far too numerous for me to mention here. The recent legalisation in the United Kingdom of the volt, ohm, and ampere is in itself a distinct proof of the familiarity with which electrical matters are treated in modern times. I have spoken of the past and present; I feel that I shall have hardly completed my task without taking a peep into the future. We read of the phonograph, telephone, telegraph, etc., having been foretold or prophesied long ago; without, perhaps, going so far as to make such distinct prophetic utterance, we can at least imagine a time not very far distant when the telephone will become universal, not only commercially but domestically, when there will be intercolonial and even international exchanges, and the telegram and cablegram a thing of the past; when at the same we are speaking through the telephone from here, perhaps to London, we shall at the same time see the form and face of the listener at the other end. Do not laugh, gentlemen; you would have laughed 100 years ago if you had been told what we should possess in the way of scientific inventions now. When we shall have air and water

ships propelled by electricity generated by a thermo-battery, burning coal instead of decomposing zinc; a time when electricity is the only motive power in existence; and when, by the development of Tesla's experiments, instead of lighting our rooms by points of light we shall have the whole of the atmosphere in a state of luminosity; when, instead of suffering from alternate droughts and floods, we shall be able to regulate and control the rainfall by means of the electric discharge—a period in which fogs will be dispersed electrically immediately on formation, and in which we shall be able to cure all disease by the aid of this potent agent, when electricity has been applied to such an extent in warfare that war without annihilation becomes impossible, and we have obtained the millennium of peace. In this address I have endeavoured to place before you some of the more remarkable developments of electrical science from the early philosophical experiments to the practical realisation of those experiments by modern inventors, who have adapted them to the requirements and comfort of the present age, and I have even attempted to see even the further developments which have yet to be made. This I have endeavoured to do without going into those minor details which are familiar to most of you, and which would extend this paper to a wearisome length. The world has seldom seen such a period of scientific unrest as the last 20 years, both in America and Europe, but of the multitude of discoveries and inventions which have been the product of that period, there are few which have been made by mathematical leaders. Most of them may be regarded as the results of investigation not of the learned few, but of the fortunate few of the comparatively unlearned many.

At the conclusion of the speech a vote of thanks was accorded to Mr. Cracknell, on the motion of Mr. H. H. Kingsbury, seconded by Captain F. C. Rowan, and the proceedings closed.

COMPANIES' MEETINGS.

EDINBURGH ELECTRIC SUPPLY CORPORATION.

The second annual general meeting of the shareholders of this Corporation was held recently in 17, St. Andrew-square, Edinburgh. Mr. Walter Berry, of Glenstriven, chairman, presided.

The report stated that there were now 206 shareholders enrolled on the list, amongst whom were a large number of prominent citizens of Edinburgh and Leith, representing a privately subscribed capital of £31,175, which places the Corporation in a very strong position locally, and the share list was daily becoming more influential. Reference was made to the negotiations entered into by the Directors with the Town Council, setting forth the position of the Company and the advantages that would result to the city were an arrangement arrived at whereby the lighting of the compulsory area comprised in the provisional order should be undertaken by it. The subject, the report continued, must shortly be considered by the Councillors, as they obtained the Royal assent to their provisional order in the beginning of last July, from which date they had only three years to complete this work within the compulsory area. Meantime, the Directors had collected a large mass of information and statistics connected with similar works, finished and in progress, throughout the United Kingdom and elsewhere, which would enable them to tender for the electric lighting of the city, should the Town Council decide on delegating their powers to the Company. In the meantime the shareholders had incurred no liability with regard to the expenses, nor would they do so unless the desired contract was obtained from the Council, when the shares would be issued to the public, and the business of the Corporation be at once proceeded with.

The **Chairman**, in moving the adoption of the report, said he had to express the regret the Directors felt in being still unable to intimate any progress towards the definite fulfilment of the object for which the Company was formed, but no one was to blame for that. Without being too pressing, the Directors had not failed to urge their claims on the Town Council, and he could not doubt that these would be favourably considered when the Council was in a position to come to a decision. They must, of course, recognise that their representatives in the Council might decide that in the public interest it would be preferable for them to undertake the work themselves, and he had no doubt that should they so decide, their decision would be arrived at on sufficient grounds. In that case the existence of their Corporation would terminate, and the preliminary subscriptions of the shareholders would be returned in full. As they were aware, the reasons why this Company was originally formed were—first, that it was deemed that there was sufficient business capacity in Edinburgh to carry out the electric lighting of our city, and that there was sufficient public spirit to form a local company for that object; secondly, that they objected very strongly to be tied to any one system. They knew that the Company against which they appeared as competitors was limited to its own special method, against which he had not one word to say. It might still prove the best, but they thought it well worth the trouble involved to attempt to keep the city free to adopt the best obtainable. Therefore, if the city entrusted the electric lighting of Edinburgh to their Company, they should do their best to keep in the front rank, both scientifically and practically. Great strides had been made within the last year in electric lighting. The recent Frankfort Exhibition had brought many useful adaptations and inventions before the public, and although it would be foolish not to recognise that many more would be discovered, they could not wait indefinitely for that. They had, at any rate, the advantage of studying many failures and mistakes, and would profit by them. He felt confident that if the Company were entrusted with the work it would be done as well as the present position of the science would admit. They were naturally anxious to have the business, but the shareholders might rest assured that although their Directors would not be greedy for profit, they would not undertake any contract which did not in their view leave a good margin for interest and risk.

Mr. George Barclay said he had great pleasure in seconding the adoption of the report, because he thought both the report and the Chairman's remarks indicated that the Directors had been proceeding on wise and prudent lines, and that being so there was good reason to believe that should the Corporation eventually succeed in getting the concession from the city on fair and reasonable terms, the same Directors would carry out the enterprise to a successful termination.

The report was adopted unanimously, and on the motion of **Sir Thomas Clark** a vote of thanks was passed to the Chairman.

MUTUAL TELEPHONE COMPANY.

Directors: A. D. Provand, M.P., London, chairman; H. T. Gaddum, J.P., Manchester; W. M. Mollison, Manchester; Councillor J. W. Southern, J.P., Manchester; John Blyth, Liverpool; James R. Paton, Liverpool. A. R. Bennett, M.I.E.E., general manager. J. Vincent Swindells, secretary.

Report of the Directors for the period ending 31st October, 1891, presented to the shareholders at an ordinary general meeting of the Company, held at the Memorial Hall, Albert-square, Manchester, on Thursday, the 31st ult.

The Directors have the pleasure of submitting to the shareholders their first report and statement of accounts, made up to the 31st day of October, 1891. The accounts do not represent an ordinary working period, but must be submitted in order to conform to the requirements of the articles of association. The capital account shows that from the formation of the Company to the 31st October, 1891, the sum of £21,539. 2s. 6d. has been expended on the construction of the Company's exchange system in Manchester, and that £1,574. 16s. 8d. has been expended in other places where it is proposed to open exchanges. The revenue account represents only a working period of four months—viz., from July 1st to October 31st, 1891, the former being the date from which, with the exeception of £191. 15s. previously charged, the Company commenced to earn revenue. This account shows a gross rental of £3,906. 5s., of which £1,145. 1s. is applicable to this period, and £2,761. 4s. has been carried forward to next account as representing rentals received in advance for periods extending beyond 31st October, 1891. The amount at the credit of the account is £378. 11s. 7d., which the Directors propose to carry forward. The business of the Company is proceeding in a very satisfactory manner. At the date of this report, 840 instruments are in connection with the Company's exchange. This leaves a large number of applicants still to be joined up, while additional applications are being received daily. Attention is also being given to the work of connecting by trunk wires the various manufacturing centres around Manchester, and your Directors hope before long to offer to the subscribers these facilities. Arrangements have been made to open call-boxes on the main boards of the Royal Exchange, and these will shortly be ready for the use of subscribers to the Company's system The Directors feel that they may congratulate the shareholders upon the Company having already proved itself an accomplished success, both in respect of the advantage of the metallic circuit (*i.e.*, the double wire), as affording clearness of speech, and as confirming the views held by the promoters of the Company that a telephone service, worked with the most modern improvements, can be supplied at rates much below those hitherto charged. The retiring Directors are Messrs. Provand and Southern, who, being eligible, offer themselves for re-election. The auditors, Messrs. Thomas, Wade, Guthrie, and Co., also retire, and are eligible for re-election.

Revenue Account, covering the working period of four months ending October 31st, 1891.

		£31,973 5 10

The ordinary meeting of the Company was held at Manchester on the 31st ult., Mr. Provand occupying the chair.

The **Chairman**, in a few words, referred to the work they had accomplished in the short period since they began operations, and proposed the adoption of the report and accounts.

This was duly seconded, and carried unanimously, several shareholders expressing gratification at the satisfactory state of the Company.

The retiring directors, Messrs. Provand and Southern, as well as the auditors, Messrs. Wade, Guthrie, and Co., having been re-elected, the proceedings closed with a hearty vote of thanks to the Chairman and Board.

NEW COMPANIES REGISTERED.

Central Electrical Company, Limited.—Registered by T. T. Hull, 22, Chancery-lane, W.C., with a capital of £50,000 in £1 shares—5,000 preference and 45,000 ordinary. Object: to carry into effect an agreement expressed to be made between Knud Sande of the one part and this Company of the other part, and generally to carry on business as electricians, mechanical engineers, suppliers of electricity for the purposes of heat, light, motive power, or otherwise, and manufacturers of and dealers in all apparatus and things required for or capable of being used in connection with the generation, distribution, supply, accumulation, and employment of electricity; to construct, lay down, establish, fix, and carry out all necessary cables, wires, lines, accumulators, dynamos, batteries, lamps, meters, works, and to generate, accumulate, distribute, and supply electricity, and to light streets, markets, houses, buildings, and places, both public and private. The first subscribers are:

	Shares.
P. H. H. Nickson, 221, Gipsy-road, West Norwood	1
H. W. Britt, Bourneside, Weybridge	1
T. Hallamore, 340, Old Broad-street, E.C.	1
J. P. O'Donnell, 2, Great George-street, London	1
K. Sande, 47 and 48, Broad-street-avenue, E.C.	1
W. Woodhead, 4, Station-buildings, West-green, Tottenham	1
H. B. Thurston, 50, Norwood-road, Herne Hill	1

There shall not be less than three nor more than seven Directors; the first are to be appointed by the signatories to the memorandum of association. Qualification, £100. Remuneration, £100 per annum each, with an additional 10 per cent. of the net profits, divisible as to the latter.

Keighley Electrical Engineering Company, Limited.—Registered by Ullathorne, Currey, and Villiers 1, Field-court, Gray's-inn, W.C., with a capital of £10,000 in £1 shares. Object: to adopt and carry into effect an agreement, made October 27, between H. Boardman of the first part, I. Ickringill of the second part, C. J. Garnett of the third part, A. Moore of the fourth part, C. H. Seed of the fifth part, and S. Hey of the sixth part, for the acquisition of the business of C. J. Garnett, now carried on at South-street, Keighley, and generally to carry on business as electrical engineers in all its branches. Registered without articles of association.

BUSINESS NOTES.

Great Northern Telegraph Company.—The receipts for the month of December were £22,400.

Eastern Telegraph Company.—The receipts for December were £55 830, as against £58,058 for the same period of 1890, a decrease of £2,228.

Eastern Extension Telegraph Company.—The receipts for December amounted to £38,898, as against £43,482 in the corresponding period, showing a decrease of £4,584.

City and South London Railway.—The receipts for the week ending January 3, 1892, were £878, as against £805 for the corresponding week last year, showing an increase of £73, and an increase of £7 as compared with the receipts for the week ending December 27, 1891.

The Direct United States Cable Company recommend an interim dividend of 3s. 6d. per share, tax free, being at the rate of 3½ per cent. per annum, for the quarter ending December 31st, 1891, payable on the 23rd inst. £5,000 has been placed to the reserve fund, and £4,982 carried forward.

Partnership.—Mr. Smeeton and Mr. Page have entered into partnership, trading as Messrs. Smeeton and Page, at 63, Queen Victoria-street, E.C. Mr. Smeeton was a pupil of Messrs. Goolden and Trotter's, and has since acted as engineer to the General Electric Company on their foreign installations. Mr. Page was manager of the same firm's supply department.

Change of Address.—Mr. G. E. B. Pritchett, of 1, Hanway-place, Oxford-street, W., informs us that he has removed to 31, Soho-square, W., and that he has taken his brother, Mr. T. W. Pritchett, late of the Metropolitan Electric Supply Company, into partnership. In future the business will be carried on at the above address under the title of Pritchett Bros.

Companies Registered during December.—The following electrical companies were registered during the past month:

California Gas, Water, and Electric Light Syndicate, Limited. £1 shares	£2,000
Chloride Electrical Storage Syndicate, Limited, £1 shares	262,500
Central Electrical Company, Limited, £1 shares	50,000
Keighley Electrical Engineering Company, Limited, £1 shares	10,000
Lightning, Limited, £1 shares	3,000
Mountain's Wire Manufacturing Company, Limited, £5 shares	25,000

PROVISIONAL PATENTS, 1891-92.

DECEMBER 21.

22,284. **An improved device for suspending electric cables or conductors.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

22,301. **An improved method of lighting railway carriages by electricity.** Sarah Jane Rollason, 50, Goldhurst-terrace, South Hampstead, London.

22,304. **Improvements in means of electric transmission for telegraphic, telephonic, and other purposes.** Silvanus Phillips Thompson, the Technical College, Leonard-street, Finsbury, London.

22,316. **Improvements in electrical distribution and transformers therefor.** Joseph Devonport Finney Andrews, 28, Southampton-buildings, London.

22,326. **Improvements in Wheatstone bridge apparatus and in the adaptation of the same to the measurement of temperatures, electric, potential, and current.** Hugh Longbourne Callendar, 24, Southampton-buildings, London.

22,339 **Improvements in primary and secondary batteries.** Nicholas Wladimiroff, 4, South-street, Finsbury, London.

DECEMBER 22.

22,352. **Improvements in electric switches.** Gwynne Ernest Painter, 11, Wellington-street, Strand, London. (Complete specification.)

22,360. **An arrangement for securing good contact in electric switches, and for avoiding dead stops in their action.** Joseph Jackson, 21, Fernhead-road, Paddington, London.

22,370. **Improvements in nautical signals or sea telephones.** Ernest Huber, Frederick Jacob Kneuper, and James Robert Davies, 321, High Holborn, London. (Complete specification.)

22,375. **Improvements in shades for gas, electric, and other lights, and in the mode of manufacturing the same.** Amédée Bidron and William Isaiah George Lewis, 38, Chancery-lane, London.

22,376. **Improvements in switches for electrical purposes.** Charles Scott Snell, and Woodhouse and Rawson, United, Limited, 88, Queen Victoria-street, London.

22,404. **Improvements in the coupling of electric mains.** Henry White Bowden, Albert Gay, and Robert Hammond, 46, Lincoln's-inn-fields, London.

DECEMBER 23.

22,473. **Improvements in electrical heating apparatus.** Carl Drevs, 323, High Holborn, London. (Complete specification.)

22,478. **Improvements in the construction and working of electric accumulators.** Illius Augustus Timmis, 2, Great George-street, Westminster, London.

22,482. **Improvements in voltaic cells.** Henry Harris Lake, 45, Southampton-buildings, London. (Edward Weston. United States.) (Complete specification.)

DECEMBER 24.

22,507. **Improvements in supports for telephone receiving instruments.** Robert Atkins Fraser and George Frederick Rowland Kelson, 4, Clayton-square, Liverpool.

22,533. **Combined portable electric lamp and battery, which may also be applied to act as a burglar alarm.** Thomas Jenner, 77, Chancery-lane, London.

22,542. **Improvements in devices for conducting electricity to lamps or the like on dining-tables or on other places where it is desirable to employ concealed conductors.** George Phillips, and George Fitzhardinge Rose, 47, Lincoln's-inn-fields, London.

22,554. **Improvements in batteries and accumulators.** Henry Harrington Leigh, 22, Southampton-buildings, London. (Johann Franz Weyde and Ferdinand Clas, Austria; and Jules Elsner, France.)

22,555. **Improvements in dynamo-electric machines.** Alexander Bernstein, 4, South-street, Finsbury, London.

DECEMBER 28.

22,575. **Improvements in dynamo-electric machines.** Rankin Kennedy, Carntyne Electric Works, Shettleston, Glasgow.

22,576. **Improvements in alternating-current generators and electromotors.** Rankin Kennedy, Carntyne Electric Works, Shettleston. Glasgow.

22,582. **Improvements in ceiling joints for electroliers and the like.** George Frederick Sanders, 37, Chancery-lane, London.

22,593. **A combined telephone and telegraph.** Frederick Harvey Brown and Wilbur F. Melbourne, 7, High-street, Haverfordwest.

22,605. **Improvements in conduits for electrical conduct rs particularly suitable for electrical traction.** Charles Frederick Parkinson, South Regent-street, Lancaster.

22,609. **Improvements in incandescent electric lamps.** Richard Ballard, 2, Clifford's-inn, London.

22,627. **Improvements in electric locomotives or electric-motor cars.** Sidney Pierce Hollingsworth, 24, Southampton-buildings, London.

22,636. **Improvements in electrical conducting wires.** Henry Harris Lake, 45, Southampton-buildings, London. (Madame Veuve Hannetelle, *née* Hortense Chapuis, France)

22,640. **Improvements in electric arc lamps.** William Brooke Sayers, 46, Lincoln's-inn-fields, London.

DECEMBER 29.

22,686. **Improvements in electric forges.** Edwin Elliott Angell, 52, Chancery-lane, London. (Complete specification.)

22,687. **Improvements in electric blank heaters for forging machines.** Edwin Elliott Angell, 52, Chancery-lane, London. (Complete specification.)

22,695. **Improvements in apparatus for relieving electrical circuits from static charges of electricity.** Oliver Imray, 28, Southampton-buildings, London. (The Westinghouse Electric and Manufacturing Company, United States.)

22,708. **Improvements in the manufacture of porous carbon for galvanic batteries and for filters.** Wilhelm Hellesen, 4, South-street, Finsbury, London.

22,718. **Improvements in machines for treating metals by electricity.** George Dexter Burton and Edwin Elliott Angell, 45, Southampton-buildings, London. (Complete specification.)

22,720. **Improved methods of and apparatus for heating metal articles by electricity.** Edwin Elliott Angell, 45, Southampton-buildings, London. (Complete specification.)

22,725. **A new or improved method of making and breaking electric circuits and apparatus therefor** William Henry Dingle and John Mackenzie Urquhart, Norfolk House, Norfolk-street, London.

DECEMBER 30.

22,773. **Improvements in and relating to electric bells and indicators.** Charles Fletcher Ennis, 31, Haselrigge-road, Clapham, Surrey.

22,782. **Improvements in electric arc lamps.** Guy Carey Fricker, 46, Lincoln's-inn-fields, London. (Complete specification.)

22,785. **Improvements in the field magnets of dynamo-electric machines.** Lazarus Pike and Edward Stephen Harris, 433, Strand, London. (Complete specification.)

DECEMBER 31.

22,817. **Improvements in dynamo-electric machines.** John Hall Rider, Northern Telegraph Works, Halifax.

22,820. **Improvements in connection with telephones.** Ernest Frank Furtado, Anders Elliott, and Chetham-Strode, Ld., 4, Moorfields, London. (Complete specification.)

22,837. **Improvements in electric arc lamps.** Hubert Hallam Bigland and John Burns, 6, Lord-street, Liverpool.

22,852. **Improvements in and relating to electric meters.** Francis Teague, 433, Strand, London.

22,854. **Improvements relating to the electrolysis of metals.** Emile Placet and Joseph Bonnet, 6, Bream's-buildings, London. (Date applied for under Patents Act, 1833, sec. 103, 17th July, 1891, being date of application in France.)

22,855. **A method of extracting chromium by the aid of electrolytic baths with a base of salts of chromium** Emile Placet and Joseph Bonnet, 6, Bream's-buildings, London. (Date applied for under Patents Act, 1883, sec. 103, 17th July, 1891, being date of application in France.)

22,856. **A method of extracting chromium by the aid of electrolytic baths with chromic acid base.** Emile Placet and Joseph Bonnet, 6, Bream's-buildings, London. (Date applied for under Patents Act, 1883, sec. 103, 17th July, 1891, being date of application in France.)

22,858. **Improvements in or connected with electrical measuring and indicating apparatus.** Erhard Ludwig Mayer, Norfolk House, Norfolk-street, London.

22,871. **Improvements relating to the employment of electricity when carrying out certain surgical operations.** John Jones Attwood, 20, High Holborn, London.

22,872. **Rietti system of electric tubing.** Charle William Clement Rietti, 14, Glasshouse-street, Regent-street, London.

JANUARY 1, 1892.

37. **Improvements in electric tricycles and cars actuated by electricity.** William Walter Gerald Webb, 9, Coppenhall-terrace, Crewe.

43. **Improvements in apparatus for electric lighting of railway trains.** Edward John Houghton and William White, 28, Southampton-buildings, London.

JANUARY 2.

86. **Improvements in electrical railways and methods of and means for driving cars and transmitting electrical energy thereto.** Francis Beatus Badt, 1, Quality-court London.

97. **Improvements applicable to the production of electric light in walking-sticks and other similar articles** Samuel Harris Levi, 115, Cannon-street, London.

SPECIFICATIONS PUBLISHED.

1890.

19,811. **Propelling vessels by electricity.** Wynne. 8d.
20,175. **Electric meters.** Frager. 8d.
20,360. **Electric meters.** Electric Meter Company and Parker. 8d.

1891.

105. **Electric conductors.** Haselwander. 8d.
285. **Telephonic transmission.** Mayer. 8d.
1,779. **Electric motors, etc.** Hartnell. 8d.
2,067. **Electrical transformers.** Baur and Dieselhorst. 4d.
3,262. **Electrical glow lamps.** Gimingham. 6d.
3,398. **Electrical burglar alarm.** Spencer. 6d.
4,583. **Electric supply meters.** Perry. 8d.
10,840. **Electric clocks.** Vander Ploeg. 6d.
14,911. **Telephone receiver supports.** Marcus. 6d.
14,912. **Telephone mouth-piece.** Marcus. 6d.
16,767. **Electric cooking and heating.** Schindler Jenny. 8d.
17,107. **Electric arc lamps.** Rider. 6d.
17,734. **Electric switches.** Linders. 6d.
18,431. **Secondary batteries.** Waddell and others. 8d.
18,641. **Dynamo-electric machines.** Kelly. 6d.
18,902. **Electric conductors.** Redfern. (Bergmann.) 6d.
18-916 **Electric car trollies.** Nuttall. 6d.
19,458. **Electric accumulators.** Thompson. (Edgerton). 6d.
19,469. **Telephones** Grove and Lehr. 6d.

NOTES.

Johannesberg is now lighted by electricity.

London Tramway Company.—A motion for the use of electric cars was prepared at the meeting of this company, but was not put, as the directors were all averse to the change.

Railway Lighting in Germany.—The General Electricity Company of Berlin has been asked to contract for the electric lighting of the Berlin-Anhalt Railway, at a cost of some £30,000.

Factory Lighting.—Mr. R. Dann, of High-street, Maidstone, has executed the laying down of the plant for the use of the electric light in the jam factory of Mr. Chambers, at Maidstone.

Dover Telephones.—The town clerk of Dover reports that two telephone companies are seeking powers of the district, and he suggests that the Town Council should take action to secure their rights.

Long-Distance Telephones.—A Boston newspaper announces that the Bell Company has secured possession of an improved telephone which will transmit whispers distinctly a distance of 500 miles.

Book Received.—Messrs. Whittaker and Co. send us "Electric Light Cables and the Distribution of Electricity," by Stuart A. Russell, A.M.I.C.E., 107 illustrations, as the last addition to their "Specialists' Series."

Royal Institution.—The first of a course of three lectures will be given at the Royal Institution by Prof. J. A. Fleming on "The Induction Coil and Alternate-Current Transformer," on Saturday, January 23.

Hamilton (N.B.).—At the meeting of the Hamilton Town Council held last week, the further consideration of the question of extending the gas works was delayed, and enquiries were ordered to be made as to the introduction of electric light.

Leith.—At the monthly meeting of the Leith Dock Commission, the Finance Committee reported that they had instructed the superintendent to report as to the cost of the introduction of a complete system of electric lighting and the probable annual cost of maintenance.

Electric Boats.—The report of the French naval attaché in Italy states that an Italian inspector, Signor Pullini, has devised a launch driven by electricity, which has been adopted by the Italian Navy, and the construction is to be begun immediately at the works at Spezzia.

Blackpool.—The Electric Lighting Committee of the Blackpool Town Council have recommended that all the members of the committee, the town clerk, and the borough surveyor be desired to inspect the electric lighting in towns recommended by the sub-committee to be visited, and to make enquiries thereon.

Dover Lighting.—The town clerk reported at the last meeting of the Dover Town Council that he had received the draft agreement from the Brush Electric Light Company, which required some rather extensive alterations and additions before being placed before the Council. It was agreed to submit the alterations to the Council.

Electric Lighting in Ross shire.—By the utilisation of the water power of a small mountain stream, a mansion in Ross-shire is being lighted up by electricity. The stream is only 12in. wide and 4in. deep, but is made to provide current for 292 incandescent lamps, and for producing warmth through a series of electric stoves.

Chicago Exhibition.—Great progress is being made in the construction of the works and buildings for the World's Columbian Exposition, and it is confidently expected that all will be ready for the installation of exhibits by October 1, 1892—seven months before the exposition will open its gates to the public.

Reading County Ball.—At the last meeting of the Reading Town Council, the surveyor having reported, as to the feasibility of lighting the large Town Hall by incandescent lamps on the night of the County Ball, that the Reading Electric Lighting Company had offered to provide, fix, and light 15 50-c.p. lamps for £10, this offer was accepted.

Rochester.—In June last the Rochester, Chatham, etc., Electric Lighting Company had to take up new premises in Chatham, their land at Rochester being given up to the South-Eastern Railway Company. Water was wanted, and, after some considerable difficulty, on Saturday last Councillor R. D. Batchelor tapped the phenomenal supply of 20,000 gallons an hour.

Liverpool Town Hall.—Attention has been called to the fact that although in most large towns the electric light is the illuminating power used in the town hall, an important city like Liverpool has not adopted the system. An offer has been made by the Liverpool Electric Light Supply Company to light the town hall on certain specified terms, but the Finance Committee have postponed the consideration of the subject.

Electric Light from a Dumbartonshire Waterfall.—Mr. J. C. White, a wealthy Glasgow chemical manufacturer, is about to introduce the electric light into his mansion of Overtaun, near Dumbarton. A waterfall at Spardie Linn, in the Kilpatrick Hills, a short distance away, is to furnish the motive power. It is said that sufficient power could be generated at the same place to light the whole of Dumbarton by electricity.

Abdullah's Palace.—The variations in tenders for the Mansion House and the Council-chamber are as nothing to those found in the 20 tenders received recently for Abdullah's Palace at Alexandria, which varied from 192,000f. up to 600,000f. It is said that the tender of a German firm for the smaller amount has been accepted, and a considerable amount of vituperation has been going on in the Alexandria press with reference to this business.

Advantages of Competition.—In his report to St. Luke's Vestry, the surveyor, Mr. M. C. Meaby, remarks, under the head of public lighting, that "the keen competition which continues between the various gas and electric lighting companies is not without its advantage in the public interest, as may be seen by the activity displayed, and the large sums of money which are being expended by the various local authorities in rearranging and improving the lighting of the thoroughfares of their respective districts.'

Dr. Joule.—Prof. Schuster made an interesting communication at Tuesday's meeting of the Manchester Literary and Philosophical Society with reference to the late Dr. Joule's thermometers, which he has lately had the opportunity of inspecting and testing. Amongst them are two which there is good reason to believe are those with which Dr. Joule's most delicate heat experiments were made, and which have considerable scientific as well as historical interest owing to the change of value still observable in these thermometers.

Pontypool.—An influential meeting of tradesmen and others was held at The Crown Hotel last week for the purpose of considering the advisability of adopting electric lighting in the town instead of gas, as hitherto. Mr. Edwin Fowler presided. After hearing a statement from Mr. J. C. Howell, of the Crompton-Howell Company, Llanelly, as to the cost of the electric system, the meeting unanimously

decided in favour of the scheme, a committee being appointed to canvass the town with a view of ascertaining the probable number of lights required.

Stourbridge.—There is an opportunity at present for bringing the advantages of the electric light to the Stourbridge authorities. After March next the contract for public lighting will be revised, and the Board intend to advertise for tenders. They are now in the hands of the gas company, and there is no competition. The annual amount is £266 for 79 lamps, including lighting and cleaning. The question of oil was mentioned, and the gas company are understood to be able to offer advantages next year. A committee, consisting of Messrs. Collens, Worth, and Shepherd, was appointed to go into the matter and report.

Dublin.—In the Dublin Town Council on New Year's Day, the Lord Mayor, in reviewing the work of the past year, referred to the progress of the electric installation, and intimated that the building for the central station would be complete in a fortnight. His Lordship also stated that the principal streets would be lighted in May, and that the Corporation would be prepared to supply current to private consumers in July. The work of laying the street mains is being actively carried on by the Irish House-to-House Company, while the generating plant is being pushed forward by the Electrical Engineering Company of Ireland.

Tramways Institute. — On Friday evening the members of the Tramways Institute, which held its meeting at Bradford, visited the Roundhay Park electric tramway and the generating station in Beckett-street, in which, naturally, they were greatly interested. Some good results should come of this visit. Several papers were read during the meeting, one referring to electric traction, which we mention elsewhere. Another paper, by Mr. H. Nott Knight, described a system of driving tramcars by gas engines, by which it was claimed the cost of traction could be reduced to 1½d. per car mile, as against 6d. by steam and 5d. by horse traction.

Electrical Apparatus.—We have received the catalogue of electrical apparatus just issued by Messrs. Dollond and Co., of 35, Ludgate-hill. We understand that this department has been-opened under the management of W. F. Berrett, late manager to Messrs. Dale and Co. Added to the world-celebrated optical instruments of Dollond, their electrical apparatus will be very well worth inspection both by private students and authorities of electrical laboratories. The catalogue contains description and illustrations of induction machines, magnetic apparatus, batteries, coils, telephones, besides apparatus for use in research or for lecture purposes. The firm also construct special apparatus for lecturers.

Electric Meters.—Messrs. Ferranti have made some further improvements in their meters, principally to meet the requirements of the Board of Trade. A cover is arranged over the works of the meter, the screw holes of which can be sealed after testing and certificate; the meter connections have a further cover which can also be sealed when the meter is placed upon the customer's premises. These meters are very delicate, starting at less than ¼ ampere in a meter registering 100 amperes—400 per cent. range. They are made for alternating and for direct current readings, and in some cases are arranged with vertical dials, though this, necessitating a worm gearing, is not so simple as the direct rotating vanes.

London Electric Railway.—The convenience of the City and South London Electric Railway seems to be put beyond a doubt, paradoxical as it may seem, by its inconvenience. Complaints are often received of the trains being overcrowded, plainly showing that the convenience of the line is felt by more passengers than can always be accommodated. No wonder the other railways are being pushed forward with rapidity. With an economical construction in the first place, and a rush for places in the second, which must be met by quicker and quicker services, it seems probable that underground electric traction will convince company promoters of its advantages before the overhead electric tramway has had much more than a chance to show its capabilities.

Durban.—The contract open for tender for the supply of electric light to the town of Durban, Natal, will be a good chance for the introduction of larger business in South Africa, and as such is worthy of careful attention. The conditions of tender are plain and straightforward, though, unfortunately, there does not appear to have been an attempt to give the exact requirements in an engineering specification previously determined upon, usually the best and most satisfactory way of obtaining tenders. The Council is prepared to grant rights for supply of current at prices to be named by the contractors, and the town will also pay an annual sum for the public lighting, the amount of subsidy to be stated by tenderers. The town is not large—24,000—of which half only are white people. The tenders must reach the town clerk, Durban, by April 30.

Electric Light for Chester.— A deputation of Chester Town Council, consisting of Alderman Gilbert, Councillor Stevenson, and the city surveyor (Mr. J. M. Jones), having inspected the central electric stations at Brighton, St. Pancras, Eastbourne, and Brompton, have reported to the Watch Committee, who recommend the Council "to vote a sum not exceeding £20,000 for carrying out the recommendations of the deputation, and to refer the report to this committee, with power to take such measures as in their judgment may be proper for giving effect to such recommendations, and to adopt and carry out such arrangements as may in their opinion be necessary or desirable in carrying out the electric lighting order of 1890, the scheme and estimates, when prepared, to be submitted to the Council before a contract for providing an installation is entered into."

Mutual Telephone Company. — The first annua gathering of the employés of the Mutual Telephone Company was held at the offices, Portland-street, Manchester, on January 8. Mr. A. R. Bennett, M.I.E.E., general manager, presided, and there was a large attendance. In the course of a short address, Mr. Bennett said they had 900 subscribers already connected; the number of messages per week was nearly 30,000, and the length of wire, if put end to end, would reach half-way between Manchester and New York. It was intended to connect the exchange with Bolton, Liverpool, and other towns in Lancashire, and they had up to the present reached forward as far as Farnworth. The success of their efforts was due in a large measure to the excellence of the staff, which had been specially recruited from all parts of the United Kingdom. The evening finished with music.

Wallasey (Cheshire).—At the monthly meeting of the Local Board of Wallasey, held last Friday, the minutes of the Gas and Water Committee were brought forward, recommending that Mr. A. B. Holmes, Liverpool, should be engaged to make a report as to the practicability and cost of lighting the district with electricity, and also as to how far the proposed new gas works can be utilised for both gas and electrical works. Mr. Heap said it was desirable that the public should know that every effort would be made to obtain all the information that was required on the question of electric lighting, and with which to guide the Board with regard to their action in extending the gas

works. Mr. Hawkins remarked it was hardly a question of providing the whole parish with the electric light, but more in the way of introducing a supplementary light supply which would perhaps save the proposed extension. The proceedings were confirmed.

Abergavenny.—Electric lighting is sometimes used as a stalking horse for forcing the gas companies to reduce their rates. Whether this is the case at Abergavenny with reference to the County Asylum, or whether there is a distinct intention to use the electric light, does not appear; but at the last Local Board meeting the Gas Committee reported the consideration of a letter from the asylum, asking for a reply to a request for reduction of the price of gas to 2s. 9d. "before the asylum authorities decided as to the use of electric light." This veiled menace, however, did not produce the effect desired, and the Gas Committee, remarking the price paid by the asylum was only 2s. 11d., refused the reduction, and the chairman pointed out that the asylum was under contract to take gas or pay for a minimum quantity for another six years. Possibly the asylum authorities will now decide that all light above that minimum shall be supplied by electricity.

Large Ammeters.—In a recent issue we mentioned an ammeter constructed by the Weston Electrical Instrument Company, U.S., to measure up to 5,000 amperes as being the largest instrument yet made. Mr. James White, of Glasgow, maker of Sir William Thomson's measuring instruments, writes to point out that he is now supplying Thomson standard balances to measure up to 10,000 amperes. Besides this he has supplied Thomson ampere gauges to measure up to 6,000 amperes for use in electrolytic processes, and also for use with electric furnaces. It is interesting also to learn that he has recently submitted estimates to the Edison Illuminating Company, of New York, for two instruments to be used on the omnibus bars of their three-wire system, one of which is to measure up to 15,000 amperes and the other up to 100,000 amperes on each side of the neutral wire. It is evident, therefore, that we can claim the manufacture of the largest ammeters for Great Britain.

Frankfort Exhibition Finances.—At a meeting of the Managing Committee of the Frankfort Electrical Exhibition, held on December 28, 1891, Mr. Sonnemann, the president of the committee, submitted a preliminary report on the financial results of the exhibition. The total expenditure amounted to 1,362,000 marks, while the total receipts were 1,514,000 marks, showing a clear profit of 152,000 marks. It is proposed to dispose of this surplus in the following manner: Gratifications and salaries to officials still employed; publication of the official report on the exhibition and of the report of the testing commission; a bonus of 15 per cent., previously stipulated by contract, to Herr Oscar von Miller, to whose efforts the success is partly due; repayment of the grant of 50,000 marks made by the municipality of Frankfort and of the grants made by the Frankfort Chamber of Commerce and two private persons; and, finally, repayment of part of the payments made by exhibitors for hire of space and supply of motive power.

Cumberland.—The following from the *Carlisle Journal* speaks for itself: "Electric lighting does not make such rapid progress as might have been expected; but local authorities are doubtless holding their hands for a while until they can satisfy themselves as to the best method to adopt and feel assured about the cost. If we except the experiments in public lighting at Cockermouth, Keswick has led the way in providing the public with the means of supplying themselves with the electric light; but other towns are on the look out. Whitehaven is pondering over the subject, and at the last meeting of the trustees an offer of a London firm to take over the provisional order granted to the Board for electric lighting purposes was under consideration. At the meeting of the Workington Town Council a committee was appointed to make enquiries and report to the Gas Committee upon the feasibility of introducing the electric light for street lighting at Workington. Whatever the result of the enquiries of the committee should be it is evidently not expected that the gas works will be materially affected, because at the same meeting sanction was given to a loan of £545 for gas extensions."

Coast Communication. — The discussion as to electric communication with lighthouses and lightships is continued in the *Times* this week by a letter from Mr. R. S. Culley, who, with reference to the experiments on board the "Sunk" lightship, says that on enquiry he finds that this ship was chosen because of its sheltered position, yet the telegraph frequently broke down, and the experiment was abandoned nearly three years ago. In this case the ship's mooring chain was made to form a flexible tube, which did not, however, prevent chafing. Mr. Edward Stallibrass, A.M.I.C.E., writing from 25, Great George-street, says he has no hesitation in saying that should the money be forthcoming for the most important work of establishing communication with our isolated rock lighthouses, there would be no lack of engineers competent to successfully utilise it. But one attempt has been made up to now, but because that was a failure we need not assume the thing is impossible. He advises the laying down of three or four cables, securing each separately, and bringing them to one main cable at the first favourable spot above the rocks. It is unlikely all would be broken at once. The main cable would be no more likely to break than other submarine cables.

Automatic Transformer Switches.—The need for some method of reducing the waste in current in alternating-current distributing systems, caused by the absorption of magnetising current in the transformer, has long suggested itself to electrical engineers working with the high-tension current. Mr. Ferranti has just constructed an ingenious piece of apparatus for this purpose, which is found to answer well. For a large building, the transformer sufficient for maximum supply, say, for instance, 25-h.p. transformer, is surmounted by a smaller one, say, 2½ h.p. The circuits are led to a double-pole tipping automatic switch, which when pulled over puts in the larger transformer. The low-tension lamp circuit is brought down and connected to contacts which float in a bath of oil — two plates being arranged to be of the same polarity. Their repulsion is balanced by the tension of a long spring until it rises sufficiently, when the repulsion is made to actuate a magnetic contact. The current is shunted, and pulls over the switch, putting in the larger transformer. The reverse action takes place when the lights are turned out, the day supply being furnished by the smaller transformer. Some of these devices have been already supplied for central station use.

Tamworth.—Very few towns in England pay for their public gas lighting at the rate of 5s. per 1,000 cubic feet. Yet this is the rate charged at Tamworth, and it is therefore not very surprising that enquiries are being made with reference to electric lighting. Mr. Henry J. Clarson, C.E., in his annual report says that one of the most important matters which will be brought before the Council during the ensuing year will be this question of lighting the borough by electricity. He states: "The Corporation is now paying nearly £300 per annum for lighting the public lamps, the gas being charged at the rate of 5s. per

thousand cubic feet, less 10 per cent. allowed for cash discount, and at the same time another large consumer is charged at the rate of 3s. 9d. per thousand. This is an injustice which no longer should be tolerated, especially when it is known there are towns similarly situated to Tamworth at the present time supplied with gas at half the price; and there are also other towns lighted with electricity under similar conditions to those that would be required for Tamworth, where the electricity is satisfactorily supplied and sold profitably at a price equal to gas at 3s. 6d. per thousand cubic feet." From the above it will be seen that electrical engineers would have an ardent advocate in the Tamworth borough surveyor.

Junior Engineering Society.—At the next meeting of this society, to be held on Friday, January 15, at the Westminster Palace Hotel, Victoria-street, the chair being taken at 8 p.m. by Mr. Sidney Boulding, M.I.M.E., a paper will be read on "Modern Applications of Electricity to Metallurgy" by Mr. George C. V. Holmes, sec. I.N.A., hon. member. The paper will deal with the refining of copper; electrolysis of sulphate of copper solution with an insoluble anode; electrolysis of sulphate of copper solution with a pure copper anode, and the resulting deposition of pure copper on the cathode; electrolysis of sulphate of copper solution with an impure copper anode; how the impurities are got rid of during the process so as to allow of pure copper being deposited on the cathode. A description and details of cost of the electrolytic methods adopted in practice for refining copper will also be given. The paper will also deal with the manufacture of finished copper articles during the process of refining, and how the metal can be deposited in a dense and tough form. Elmore's system of burnishing during deposition will be described, and its advantages pointed out. Finally, the manufacture and cost by this process of tubes, rollers, hydraulic rams, sheet copper, wire, and tape for electric lighting will be gone into. The paper promises to be interesting and useful.

Cambridge.—An enquiry has been held at Cambridge by the Local Government Board into the application to borrow money for purposes of electric lighting. It was proposed to borrow £35,000. Prof. Garnett gave details stating they intended to use the Parsons steam turbine, driving alternators at 2,000 volts. He expected the actual cost to be £24,300, but he recommended the larger sum in view of extension of mains. The Master of Peterhouse spoke in opposition to the scheme, thinking a separate company would be best. He thought, however, that if the application were granted, opportunity should be given to consider whether direct current would not be best to adopt. Prof. Ewing, in reference to this, said it appeared from figures published by the companies that the consumption of coal for continuous was not much more than half that required for the alternate-current system. Prof. Garnett admitted that for the compulsory area with a proper supply, the continuous current might be cheaper, but thought on the whole alternate currents would be best. Alderman Balls, chairman of the Gas Committee, referred to the scheme as an unlimited company using the money of the ratepayers. He would prefer to see a private company, strongly objecting to the money of that town being used for speculating. The enquiry was concluded, though, of course, the result is not known.

Animal Electricity.—The series of lectures given by Prof. M'Kendrick, at the Royal Institution, on "Life in Motion," came to a close on Saturday. Though not trenching on the domains of practical electrical work, investigations into the electrical action of the living body, such as brought forward by these lectures, have not only immediate scientific interest, but may possibly lead to useful results in modifying our knowledge and use of condensers, and in stimulating the search for a means of economic generation of electricity by direct consumption of carbon. That there was in reality a distinct electrical action of the human body, Prof. M'Kendrick seemed to take as proved, and showed the effect of animal electrical currents by means of a very sensitive galvanometer. Current from animals such as the torpedo fish had long been known, but it was much disputed whether there was such a thing as an electric current from man. This man-current he demonstrated by putting his hands into a three-quarter per cent. solution of common salt contained in two flat vulcanite dishes. The effect upon the galvanometer was greater as the number of fingers inserted was increased, and was greatest when the muscles of the arm were contracted. There were no fewer than 50 species of animal that were living electric batteries, though only five or six were generally known. In concluding the lecture, he warned his hearers not to suppose that the final settlement of these questions had been reached. Many problems awaited solution, and he urged that everyone should keep an open mind for the reception of the truth, from whatever quarter it might come. The lecture and the experiments were heartily applauded by a large audience, which included the Lord Chancellor, Sir F. Bramwell, and a number of well-known scientific men.

Walsall.—At the meeting of the Walsall Town Council on Monday the recommendations of the General Purposes Committee, with reference to electric lighting and traction, came before the Council. These recommendations were, that the Council provide an electric lighting plant on the lines suggested in the report of Mr. F. Brown, A.I.E.E., at an estimated cost of £21,450, and that the common seal be affixed to an agreement with the South Staffordshire Tramways Company for the erection of iron poles in the public streets for the working of the lines of tramways within the borough by means of overhead wires. With regard to the electrical scheme, the Mayor said Mr. Brown's estimate was that, supposing 2,000 lights, of 16 candles each, were taken, there would be a profit of £1,266 a year. That result might not be attained, but at all events there would be a great improvement in lighting, and they had sufficient reason to believe that 2,000 lights would be taken. In Birmingham light could not be produced sufficiently fast to meet the demands of customers, and he thought the authorities of the city had made a mistake in not taking the electric lighting into their own hands. The area, he explained, in answer to questions, included the streets in the centre of the town, and the scheme would eventually be extended to the whole of the borough. Alderman Lindop, as a member of the committee, added that he should do his best to get the scheme ready in six or eight months—certainly for next winter. As to the agreement with the tramways company, the town clerk and the mayor explained that the feeder wires, except in cases where special permission was given, would all be underground, and the trolley wires overhead. Every seven years the Council would be entitled to revise the agreement with the company. The cars would be much improved. The right had been reserved for the use of the poles for electrical or gas lamps, and the use of the poles for advertising was absolutely prohibited.

Steam or Electricity for Tramways.—The incursion of the electric tramway at Leeds has roused up the tramway companies of the North, and some pretty little discussions are likely to result, from which we hope electricity will come out victorious. The subject has been

taken up by Mr. Vaux, manager of the Bradford Tramway Company, who is evidently willing to be converted by advocates of electricity, but is not yet converted. The question is not between horses and electricity, or even between cable and electricity, with Mr. Vaux, but with electricity as against steam—steam meaning in his case compound tramway engines. He does not refer to the convenience or cleanliness, questions in which the public are more interested than the company perhaps; but discusses simply the item of cost of hauling and management. The engine most suitable for tramway work, according to the experience of the manager of the Bradford tramways, is one approaching the good engine with surface condensers. The Bradford company have now seven such engines, which show a saving of 25 to 33 per cent. over other engines. The following figures are given: The engine was twice the weight of the car it had to carry; the weight of the rails had been increased from 50lb. per yard to 106lb. per yard, the best form being girder rails laid in concrete 6in. to 9in. thick. The tramway engines have a tractive force of 4,536lb. on the drawbar, and were calculated to haul 17 tons up an incline 1 in 17, or 112 tons on the level. The cost of the Bradford tramways is 9·38d. per mile, including running, management, and maintenance. With reference to electricity, Mr. Vaux remarks that it had been stated that electricity would save 3d. a mile, but he scarcely saw how it was possible. The mere cost of hauling at Bradford was only 4½d., and a saving of 3d. would leave only 1½d. a mile, barely sufficient to pay men. Repairs, he thought, would be increased, and possible rent and cost of licenses. He failed to see how an economy can be effected. It will be for electrical engineers with these details before them to convince Mr. Vaux to the contrary. The item of 4½d. is low, much lower than usually taken as the cost of steam hauling, but it seems probable that depreciation, a heavy item in steam tramways, is not therein taken into account.

Inverness.—At a meeting of the Police Commissioners in committee on Jan. 6th, a report by two engineers on the practicability of introducing the electric light into Inverness was discussed in connection with a proposal to extend the gas works at a cost of £10,000. The report described a number of schemes for obtaining water power for turbines, and recommended one whereby the necessary power could be got from the Caledonian Canal at the Muirtown Locks, Inverness. The report stated that "on the Muirtown or north side of the canal a working fall of 28ft. can be arranged from the top of the locks to the basin, according to designs which we have sketched and estimated for. This fall gives 200 h.p. with a discharge of 4,722 cubic feet of water per minute, 600 h.p. with a discharge of 14,240 cubic feet, and 1,108 h.p. with a discharge of 26,180 cubic feet. A supply for 600 h.p. would cause an average velocity of less than one-seventh part of a mile per hour in the canal, and for 1,108 h.p. an average velocity of one-fourth of a mile per hour, the central surface velocity being slightly more. For this place we have designed an arrangement for turbines, each yielding 260 h.p. when using 6,140 cubic feet of water each per minute; or, with both at work, 520 h.p. with 12,280 cubic feet of water per minute. The cost of the two turbines complete, with the necessary shafting, pulleys, governors, sluice gates, and grating, erected and ready for belting on to the dynamos, would be about £1,550. The lead, tail race, and by-wash would cost about £3,050, and the turbine and dynamo house with foundations for four dynamos and space and foundations for two engines if required, and with tail race underneath and with lead, about £1,400. The by-wash and sluice gates required at Dochgarroch Locks would cost about £1,080, and an overflow for the canal basin about £120. This makes the total cost of the complete works and turbines for 520 h.p., £7,200. The cost of a smaller or greater power of the same design can be given if required. The electric cable can be taken across under the canal at the end of the stone invert below the swing bridge." It is understood that this scheme is the one that would best suit the Canal Commissioners, because the discharge from the turbines could be used for raising the level of the canal basin when required for deeply-loaded ships, for which the normal depth of the basin is not sufficient. Along with this scheme a fall of 16ft., with the same amount of water, might be worked from the overflow of the canal basin at the end of the sea embankment. With the discharge of 12,280 cubic feet per minute it would yield 297 h.p. It was resolved to have the report printed before it is finally disposed of, and in the meantime it was agreed to recommend that, whatever may be done with the electric light, it is essential to extend the gas works.

Annual Dinner.—On Saturday last the dynamo department of Messrs. Johnson and Phillips held their second annual dinner at East Greenwich. The dinner was highly successful, over 80 sitting down to a substantial repast, under the presidency of Mr. S. Sudworth, chief foreman of the dynamo department, who was ably seconded by Mr. Chennery, foreman of the engineering department, and Mr. Lawrence, of the submarine department. There were also a number of engineers of other firms present—Mr. Jones, engineer to Messrs. Drake and Gorham; Mr. Miller, electrical engineer to the Bank of Australasia; Mr. A. J. Upton, engineer to the Union Bank of London; Mr. J. N. Cooper, of the Edison-Swan Company; Mr. Evered, electrical engineer at St. Pancras, and others. Mr. Sudworth, in giving the health of the firm of Messrs. Johnson and Phillips, said that the business was going up by leaps and bounds. Their dynamos were growing larger, while more of them were turned out, and the manufacture of the D.P. accumulator, he thought, promised to become almost more important than that of dynamos. The firm's products now went throughout the globe, and in Africa, China, as well as the European nations, the dynamos and lamps made by the men then at dinner were used for electric light. He paid a great tribute to the kind and considerate way in which the firm treated their men. No one, he thought, could ever wish to be better treated than they were. Every consideration was shown for their comfort and intellectual aid, as the beautiful library lately established served to show. The toast was responded to by Mr. Chennery, who was evidently, from his reception, as much liked for his good nature as respected for his good discipline. "Harmony between men and employés" was his watchword. The health of Mr. Gisbert Kapp was proposed by Mr. Evered (lately with Messrs. Johnson and Phillips, but now in charge of the Kapp machines at the St. Pancras central station) in very sympathetic language. He had worked for many years under Mr. Kapp, who remained to workmen as well as others the same kindly, courteous gentleman he always had been. Mr. Pierce also spoke in answer to enthusiastic calls. Mr. Lawrence, as the oldest employé, and at one time timekeeper and only foreman, spoke of the growth of the works, and hoped they would all long continue in the same firm. The evening was finished in fine style with songs, of which those with a fine rousing chorus were best appreciated. Mr. William Davis, who acted as pianist, was to be complimented on his performance. The general good feeling and enthusiasm seems to augur well for Messrs. Johnson and Phillips, and the men will doubtless look forward to many equally successful dinners

THE CRYSTAL PALACE EXHIBITION.

"Will the Exhibition be a success?" was the question asked by a gentleman upon getting out of the train at the Palace on the opening day. Such a question, too, will often be asked during the next few months, and to it time alone can give a definite answer.

The Exhibition was opened without ceremony on Saturday, but we understand that in about another week there will be a formal visit of inspection, and possibly some specifying. It is expected by that time the laggards in love—no, in preparation will have put in their time, completed their exhibits, be ready for giving information and for receiving congratulations, and—orders.

The first edition of an exhibition **catalogue** is rarely complete, and we should perhaps defer our remarks, but an excellent plan has been followed in preparing a series of short essays of a popular character to introduce the separate departments to the visitor. This work has been left in the able hands of Mr. H. J. Dowsing, who undoubtedly must have felt himself heavily handicapped in attempting to cram a mass of interesting information into the small space of two or three pages. We believe the general public will rightly appreciate this endeavour to give them trustworthy information in a simple manner.

The backwardness of many of the exhibits, and especially those in the machinery department, makes it difficult to adopt what by many would be thought the best method to describe the exhibits. The scheme we propose to adopt, however, will need little or no alteration. It will be admitted at once by experts that there will necessarily be comparatively little that is new from a technologist's point of view. It will be also admitted that the main object of an exhibit is to let the world of visitors and the world of readers learn the specialities of the exhibitor's manufacture. The technical journal, then, should, in our estimation, become rather more of a go-between from the exhibitor to the general public—the ultimate buyer—than from the technologist to the technologist.

When and how to begin is the difficult point to decide. However, as every eye will nightly be turned towards the brilliant screen of incandescent lamps exhibited by the Edison-Swan Company at the end of the North Nave, let us turn thitherward. At the time of writing the screen is incomplete, but sufficient lamps are wired thereon to show what a gorgeous flood of light there will be when fully complete. Underneath the screen is the stand of the company, which contains a fine assortment of the manufactures of the company. When finished we will visit it again. Next, in the centre of the nave, is the large, varied, and excellent display of the Post Office. Here we have the historic apparatus of telegraphy on four long counters. A day—nay, a week—might be spent around these exhibits in tracing the gradual development of telegraphy, as telegraphy is understanded of the people who do not usually place telephony under the same ægis. But telephony, as we shall see by-and-by is well represented further along. The extreme points in the telegraphic display of the Post Office are to be seen in the various (1837) instruments of Cook and Wheatstone, in the first of which five needles and five line wires were required, and the other extreme in the beautiful multiplex apparatus of to-day, by means of which half-a-dozen messages, or rather half-a-dozen instruments, are in communication with only one line wire. Men who are approaching the age of threescore years and ten can, or ought, to well remember the introduction of telegraphy, and, of course, the astounding development of all things electrical since that time. Their starting point at this exhibition should be the Post Office exhibit, and then passing around the aisles and galleries of the Palace they would have presented to them an epitomised history of their lifetime so far as electrical developments are concerned. Commencing with telegraphy, what are the great departures? Electro-deposition was soon born, and now claims thousands of labourers. The electric light in the forties had a kind of will-o'-the-wisp existence. Its turn had not come, but men prophesied, and had no honour. In the beginning of the fifties came submarine work, and for many years claimed great attention, till, after herculean efforts, it was proved a success. Meanwhile, that will-o'-the-wisp would dance backwards and forwards, and throw a glamour over men's minds, but its time was not yet. The seventies were to inaugurate a new era—a new development of telegraphy—a development to enable us not only to convey signals but sounds of speech, was ushered in, and is now enjoying a flourishing manhood. And the electric light came also to stay. Gramme, Siemens, and Jablochkoff in 1878 paved the way. Then came a hurricane, and the 1881 Exhibition at Paris and the 1882 at the Crystal Palace took the world by storm. The success of electric light was demonstrated. Incessant activity gave us the Planté secondary battery and its successors. Inventors followed Gramme and Siemens by the hundred, and through the eighties we have witnessed a feverish excitement which is carrying electrical matters forward by leaps and bounds. This is but a slight indication of what the old man might think in his wanderings among the stands. But we must be more precise. Opposite the Post Office exhibit is stand No. 147, belonging to **The Mining and General Electric Lamp Co.,** a representation of which our artist has enabled us to produce. This company appeals to us metaphorically for consideration. Previous to a visit to the 1881 Paris Exhibition, Mr. Desmond FitzGerald had shown us experiments he was making and investigations he was carrying on to attempt to make more perfect secondary batteries than were public

Lithanode Electric Mining Lamp.

property at that time. We reminded Mr. FitzGerald that he and others had worked in this direction as far back as 1863. While at Paris a conversation with Mr. Crompton ended in a promise to bring him into communication with Mr. Desmond FitzGerald. Subsequently they met, but afterwards drifted apart—Mr. Crompton to develop his business into the gigantic concern it has become, Mr. FitzGerald to the laboratory to perfect his "lithanode," the name he has given to the material he uses in his secondary battery. After many vicissitudes the Mining and General Company was formed to exploit Mr. FitzGerald's, Prof. Frankland's, and other methods of manufacturing secondary batteries, and to carry on the business of electrical engineering generally. For some time there was lacking a good business head, but it seems these difficulties are being surmounted, and under the energetic and capable management of Mr. J. T. Niblett the company is rapidly assuming its right position, and placing its specialities on the market. The stand comprises a dark room, wherein to show more effectively the capabilities of the small hand lamps and miner's lamps, in which direction particular attention is being given. Mr. N. Story-Maskelyne, M.P., as many of our readers know, has paid great attention to all that concerns the safety of miners, and no doubt it is due to his initiative that the company of which he is the chairman should specially examine into the merits of secondary batteries for lighting purposes in mines. Thus we find, as we should naturally expect, the company's

exhibit comprises, among other things, a good display of the metal-cased safety electric hand lamp, which has been specially constructed for use in such places as coal mines. In designing it every precaution has been taken to ensure perfect reliability. It will be found to withstand without injury all ordinary usage and the accidental rough treatment incidental to employment in coal mines. The lamp consists of a small two-cell battery of the lithanode type, mounted in an outer steel protecting case. A circular switch serves to throw the lamp in and out of action. Insulating charging terminals are placed above the lantern bezel, and these are covered by projecting lugs attached to the cover, so that when the lamp is in action the cells cannot be short-circuited, and therefore all possibility of sparking is avoided. When the lamp is used in coal mines the bezel carrying the glass glow-lamp protector may be secured against removal by means of a lead locking-pin. The ordinary full-size lamp weighs about 4¼lb., and when fully charged it will run a 1-c.p. glow lamp for a period of 12 hours. The actual cost of the electrical energy consumed is about one-tenth of a penny per shift of 12 hours. The company's miner's lamps have now withstood the test of time, and from the very satisfactory manner in which they have passed through some most severe practical trials they may be relied upon to fulfil all the requirements of a nearly perfect electric safety hand lamp. This lamp is known in France, where it is much appreciated, as the "Stella" safety lamp. Other forms of miners' lamps are also shown. Lithanode batteries of a portable nature, and mounted in fancy wood cases, are to be seen. Some of these are adapted for use in gas works, petroleum ships, gunpowder mills, and similar places where an absolutely safe illuminant is required. Four, six, eight, and ten-cell batteries, suitable for carriage lighting, or domestic requirements, are shown in action. A case containing electrical measuring instruments, automatic cut-outs, hydrometers, and other secondary battery accessories may be seen. Batteries for house lighting, traction purposes, military and naval use, medical and dental purposes, are also shown. Some specially constructed cells useful for actuating telegraphs and telephones are to be seen. Some of the batteries have been under trial at the General Post Office, and are giving every satisfaction. A variety of lithanode-zinc cells are shown. This combination gives the highest known E.M.F. of any practical cell.

To other exhibits of the company we shall refer in another issue.

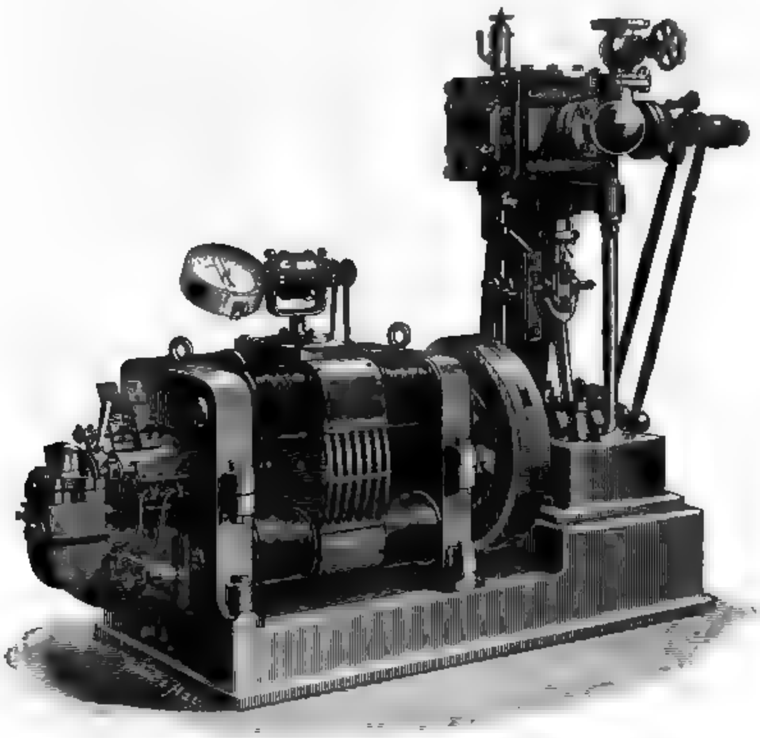
A little further down the nave we come to one of the most prominent exhibits, that of the **Fowler-Waring Cable Company,** and it had the almost unique peculiarity of being quite ready on the opening day. This stand, No. 90, which we illustrate on next page, is devoted to wires, which, like the rats of the poem, are of all kinds, from the smallest to the largest in common use. Here we find concentric wires, lead-covered wires, armoured wires, wires and cables for electric lighting, and for telegraph and telephone work. A pyramid 26ft. high is formed of lengths which have been cut from representative cables manufactured at their North Woolwich works for our own Government, for the French Ministry of Posts and Telegraphs, and for the Government of Queensland. There are also specimens of the cables used for connecting the London telephonic centres to the Paris telephone cable; and among the more important electric lighting cables are sections of the high-tension distributing mains which are employed extensively by the London Electric Supply Corporation. A large number of cable joints, jointing tools, and junction-boxes are also exhibited, together with the diplomas and medals which had been awarded to the company.

It is perhaps a little invidious until all are complete to indicate any one exhibit as the best, but we certainly feel inclined to mention that of the **Brush Electrical Engineering Company** as one of the most important and imposing of the whole Exhibition. Their exhibits are divided into two—one in the Main Transept, and the other in the Machinery Hall. The one includes what is termed stationary exhibits, and the other moving machinery, though, in fact, much of the former will be driven by electric transmission of power from the Machinery Room and shown in motion. Standing in the centre of the transept, just opposite the entrance to the Palace from the railway station, the Brush Company could hardly wish for a better position for the exhibition of the products—dynamos, arc lights, motors, tramcars—and the very handsome manner in which they have been mounted serve the better to show them off; while in the Machinery Room the fact that the Brush Company can label their machines "exactly the same as used for lighting the City of London" will cause the attention of private persons, engineers, and members of local authorities to be turned with great interest upon their

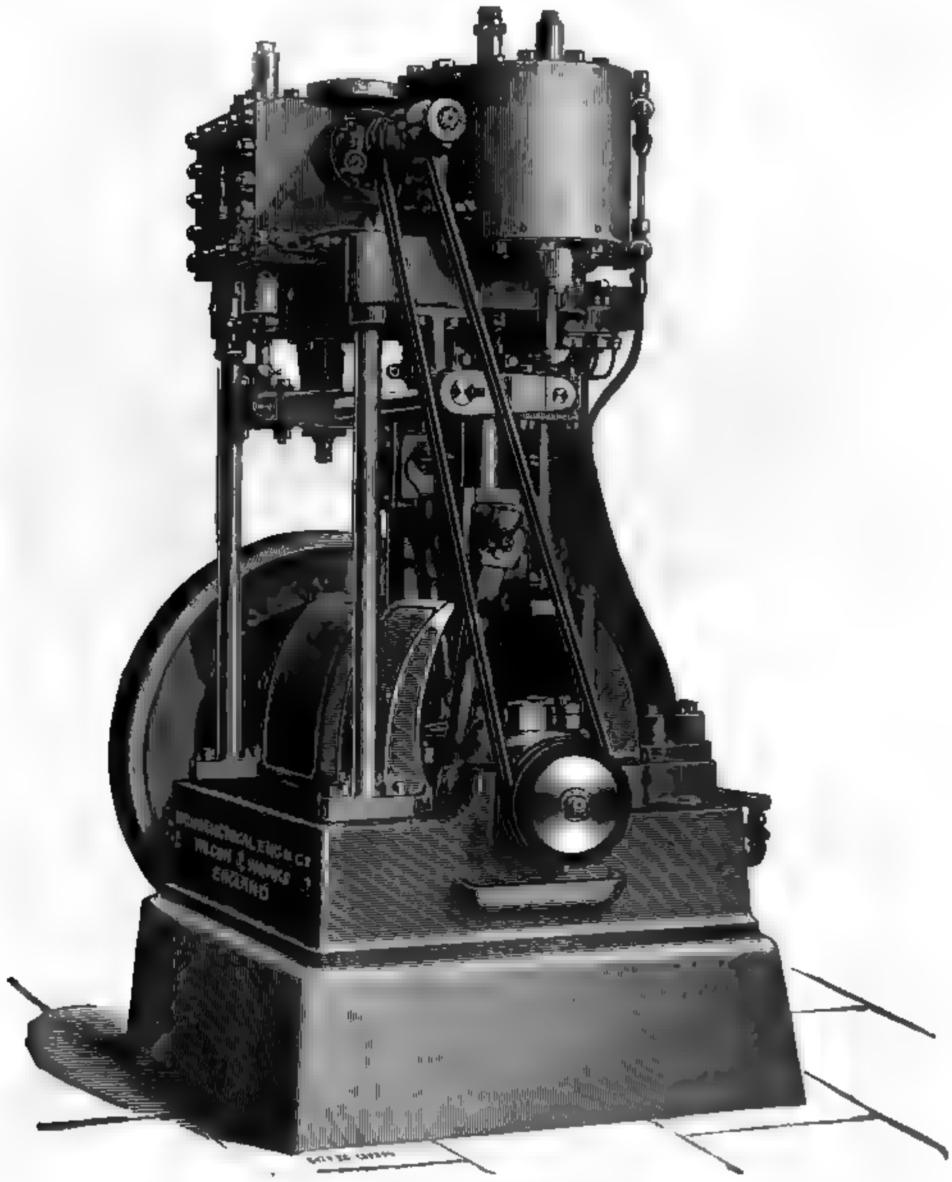
exhibit. This Brush exhibit in the Machinery Room will certainly be a fine sight when all is in working order, and additional interest is given by the fact that all the plant—engine, dynamo, and fittings—were made by the company either at their works in Lambeth or at Loughborough. There are five sets of engines and dynamos, ranging from the large size used at the City of London Electric Light Company's station at Bankside, down to the natty little combined plant of 10 h.p. to light a private house—and even smaller sizes still of combined plant are shown in their stationary exhibit. We give an illustration of the specially designed Raworth engines, made by the Brush Company at their Falcon Works, and used either for driving by belting or for driving direct by "Raworth" flexible coupling. The first exhibit is the central station plant above mentioned, as used for the City lighting. This comprises a vertical engine of 280 i.h.p., driving a Mordey alternate-current dynamo, giving 100,000 watts (100 units), capable of supplying 3,000 to 4,000 8-c.p. lamps. The following are the particulars of the engine: high-pressure, compound, working at 140lb. pressure, cylinders 15in. and 25in. by 16in. stroke, running at 168 revolutions a minute. This engine drives the alternator by means of an endless rope gearing, running in eight grooves and over a "jockey" pulley. This dynamo is not the largest the Brush Company make, the largest at present made being of 200 units capacity, or double the capacity of the one shown. The current from this dynamo will be led from the Machinery Hall to a similar alternator at the other stand. This second Mordey alternator will be run as a motor, demonstrating the utility and efficiency of these machines for the electric transmission of power, either for the utilisation of water power to light a town from a distance, or for driving a factory engine or such purpose.

The second engine and dynamo shown by the Brush Company is only of 75 i.h.p., driving one of the famous Brush arc light dynamos. The details of the engine are these: cylinders 9in. and 15in. by 10in. stroke, 217 revolutions, 140lb. steam pressure. The dynamo is one of the "8 L" type, capable of supplying current for 55 Brush arc lamps in series for town lighting. This dynamo is also driven by endless rope gearing with eight grooved pulleys, the rope passing over a jockey pulley for tightening. The dynamo will not work at its full load, at any rate at present. The current will be led to the six lamps on the Brush Company's masthead light in the centre of the transept, and will also supply lamps at each corner, on the specimen City lamppost, and four or five in the Machinery Hall. The third set of machinery is a 50-i.h.p. vertical engine, driving one of the Brush Company's Victoria incandescent dynamos. The engine has cylinders of 7½in. and 13½in. by 8in. stroke, working at 250 revolutions. The dynamo is such as used generally for lighting institutions or large private mansions, and is of a capacity of 36,000 watts—equal to about 1,000 8-c.p. incandescent lamps. The fourth set is particularly interesting to intending purchasers of electric lighting apparatus, being a combined plant in which the Raworth vertical engine is connected direct to the Victoria incandescent dynamo by means of Raworth's patent flexible friction grip coupling, mounted upon a combined bed-plate. These sets of combined engine and dynamo make exceedingly compact and useful electric light plants, and are much used for shiplighting and other places where the question of space is one of importance. The engine in this case is of 16 i.h.p., single cylinder, size 8in. by 6in. stroke, driving an 18-unit dynamo. We give an illustration of this set. A sensitive governor is driven from the engine shaft, and above the dynamo is mounted a tachometer, or speed indicator, driven from the dynamo shaft. A fifth exhibit, comprising another combined plant of 10-i.h.p. engine, coupled by flexible coupling to a small Victoria incandescent dynamo, is used to supply the current for exciting the field magnets of the large alternator.

Returning now to the Main Transept, we will mention what the Brush Company show here; but we intend later on to refer again to these more in detail. In the first place, an enormous mast lamppost, built up of tubular plates, will be sure to



Brush Company's Combined Plant. Victoria Dynamo and Vertical Engine.



The Brush Company's Vertical Engine.

attract attention, reaching as it does nearly to the height of the roof of the Palace, and carrying six arc lamps. A specimen lamppost, as used in the City, will shed light upon the stall, while at each corner other Brush lamps will be lighted. In the centre of the stand is a beautiful specimen of tramcar, to be used for electric traction, made at the company's

Falcon Works, Loughborough. In the front of the stall is a 50-unit Mordey alternator. This we have already mentioned as intended to be shown running as a motor. Down one side of the stand are a series of combined plants of engine and dynamo, of 6 h.p., 10 h.p., 16 h.p., and 30 h.p., for house and shiplighting. These will be shown in motion, the dynamos acting as motors. On the other side is an equally interesting set of Brush arc light dynamos for 2, 4, 10, 16, 25, and 55 lights each. In the centre is an enormous Blackman air-propeller, as used for ventilating mines or breweries, or for forced draught. An important exhibit is also that of a 24-h.p. electric motor driving a quartz crusher for mining purposes. The crusher is made by the Sandy Croft Foundry and Engine Company, of Chester, the motor being one of the Brush Company's Victoria machines. We must not forget to mention also that in front of the exhibit we see a pyramid of the Brush Company's transformers used for town lighting on the alternate-current system. In this company's exhibits we thus find almost the whole range of electrical engineering covered. From small installations of two arc lights, or 20 incandescents, up to the large engines and dynamos, with their switchboards and lamps, used for central supply stations for town lighting, sets of electric light plant for ships, ventilating fans, transmission of power for mines, for quartz crushing, for electric tramcars, the lighting of docks, of city streets, projectors for naval and military use, dynamos for colliery lighting, motors for hauling are all shown; and when it is remembered that the company not only supply but have manufactured the whole of the machinery they now exhibit, the commanding position of the Brush Electrical Engineering Company can be thoroughly appreciated.

The exhibits of **Messrs. Crompton and Co., Limited,** are conspicuous all through the Palace. At one stand we see a projector ready to throw its vivid rays in a stream of light wherever directed, while all around are dynamos made by this company. A little further down is a large crane worked electrically, and it is this item of their exhibit we choose for description in this issue. The crane shown is the original model made in the early part of 1888, and is claimed to be the first one constructed in this country. It was the outcome of a large number of experiments, and the cranes that have been turned out by the firm since the above date have been made on the same principle, and have in every case worked very satisfactorily. The first crane made by Messrs. Crompton was supplied to Mr. Hermann, of Dodd-street, Limehouse, for work in a timber-yard, and is still employed there, having given every satisfaction. We believe it is a fact that Mr. Hermann's place has been burned down twice, and great difficulty was experienced in getting the insurance companies to cover it, and then only at the high rate of 25s. per cent. Immediately on the introduction of the electric crane, and the consequent abolition of a boiler needing fire, Mr. Hermann's premium was reduced to 12s. 6d. per cent., and this on an insurance of £40,000. The crane hoists, travels, and slews at the same time. The attendant having no fires to stoke, nor smoke to prevent him seeing what he is about, can perform his work with very much more ease than with a steam crane, and at a far more rapid rate. In Mr. Hermann's case a large dynamo is used for lighting the works, and leads are taken from this machine to run the crane—no extra attendance is therefore required for driving the generating machinery. In this connection we may mention that, owing to the satisfactory working of the crane at the above timber-yard, Messrs. Crompton have received orders not only for similar plant, but also for electric capstans and haulage plant generally. The crane shown at the Exhibition is driven by a five-unit motor taking 45 amperes and 110 volts. It will hoist, we understand, a weight of two tons, at the rate of 80ft. per second. The motor is connected by a friction wheel to an intermediate shaft, which is connected by a spur wheel to the drum-shaft. This latter contains a clutch to throw the drum in or out of gear. A powerful band brake is provided on the drum and is worked by a treadle. The slewing is done by intermediate gearing from the intermediate shaft, and is controlled by a hand lever conveniently placed. The crane is made to travel by the movement of a hand wheel in a manner similar to that by which the operation of slewing is carried out. It is fitted with Crompton's patent sight-feed lubricators, and all the latest improvements. Current is supplied to the crane by two rails, along which are laid copper strips. The rails are carried on Crompton insulators similar to those used in his underground mains, and are laid between the travelling rails. The current is taken off by an improved form of collector gearing with carbon brushes. A double-pole switch and fuse are interpolated in the circuit. The crane will be exhibited at work at certain stated times during the Exhibition, due notice of which will be given.

Crompton's Electric Crane.

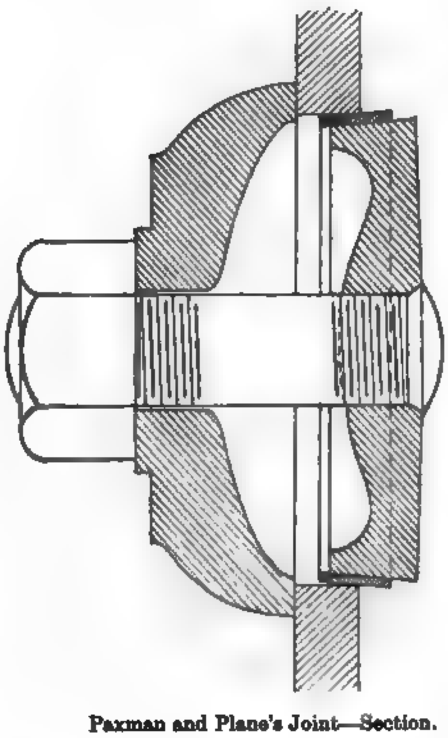
Close by is another early complete and excellent exhibit, Stand 173. This is the exhibit of the Western Electric Company, and, as we remarked last week, have a comprehensive exhibit covering the whole field of telephonic requirements, of which we hope to give full particulars in

the course of our review of the Exhibition. We select for illustration this week one of the smaller switchboards shown by them. It differs from their well-known Standard model in having no clearing-out drops, one of the subscriber's drops being left in circuit for clearing, as in a single-cord board.

It will, perhaps, be advisable to say little of the machinery department for the moment, except the boiler-room, which is practically complete. **Davey, Paxman, and Co.**

Western Electric Company's Telephone Switchboard.

reign here supreme, and, under the indefatigable activity of Mr. H. D. Wilkinson, this firm seems destined to add still further to the high esteem in which its productions are held. On the left-hand of the boiler-room is a battery of eight steel locomotive type boilers used for supplying steam for driving the engines during the Exhibition. The boilers contain about a total heating surface of 5,640 square feet; they are provided with steel fireboxes, and are made in the best known and most modern manner, being well stayed and tested by hydraulic pressure to 250lb. per square inch for a working pressure of 140lb. per square inch. A steel steam receiver runs the entire length of the boilers, connected to each by a separate stop-valve, so that either or any of the boilers can be shut off immediately if necessary. The object of the receiver is to give dry steam to the engines, and to turn back to the boilers any condensed steam. The pumps feeding the boilers are provided by Mr. A. G. Mumford, of Colchester, and the injectors are of Messrs. Gresham and Craven's manufacture. The boiler fittings are asbestos-packed, and the water-gauges are fitted with protecting shields. On the right is one of Paxman's patent new type water-tube boilers, in boiler-house, used for supplying steam for driving engines during the Exhibition. The boiler contains about 1,572 square feet of heating surface. This boiler is made on a new principle, in which it automatically separates any water in the steam. The joints are made on Paxman and Plane's patent metallic principle, and are a very great advance in this direction. This is the first time this boiler has been exhibited to the public. It contains several new features, principally as to the circulation and separation of steam from water. Furthermore, it is made in sections, which are very readily removable and are much more handy for repairs than is common to many of the types of these boilers. The joint for the headers for getting at the tubes are of Paxman and Plane's patent above referred to (see annexed sketch), a pattern of which can be seen at their stand. This is a very simple, but at the same time serviceable joint, and will, we expect, come into general use, not only in this type of boiler, but for manholes and mudholes, etc., in other kinds of boilers. The sketch shows the plan as being round, but the joint can be made any shape. The way to break the joint is by unscrewing the nut and pushing the small door inwards. The metallic ring is made of pliable metal, so that it is quite easy to spring and alter its shape to enable it to draw through the opening. After the ring has been removed, then, the door can be easily drawn through, as will be seen from the sketch that the door is smaller than the opening made in the plate. The hole is made conical or taper, with the largest taper on the inside, and the metallic ring is made precisely the same taper as the hole so as to fit the hole. The door is made with a slightly less taper, so that the joint is made on the outside edge of the door. The joint possesses the following advantages: It can be quickly broken and remade, and when made it is perfectly tight. The greater the pressure inside the tighter the joint, as the pressure assists in keeping the joint tight. It is very lasting, and the metallic cover is almost indestructible and will last for many years. It is very cheap and always reliable, and being so easily and readily made, as above described, it enables the boiler to be taken to pieces for examination with a minimum loss of time. This is an advantage not hereto obtained, and we believe this joint will become that of the future and have a great sale, as Davey, Paxman, and Co. are willing to grant licenses to all makers of tubular boilers. The other exhibits hereafter.



Paxman and Plane's Joint—Section.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C H. W. BIGGS, *139-140, Salisbury Court Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

1892.

We have made some endeavours to gather opinions as to the most important points needing elucidation in central station work. Well, we have obtained opinions, but for practical use they can hardly be classified to advantage. Most electrical engineers with whom we are brought into contact have sufficient faith in their own powers to say, Give us the opportunity to instal a central station, and we will show that it can be done satisfactorily. In fact, we are more convinced than ever that there must be some diversity in practice, and that the system followed in one district with the best results may not be so suitable to another district. In the majority of cases the consensus of opinion is in favour of sub-stations. Though it might be thought otherwise, there seems to be a growing feeling in favour of accumulator sub-stations. No doubt the future will make several points clearer, and as regards systems of mains will show how far maintenance must enter into consideration in designing the original system. The survival of the fittest involves time, and as yet deterioration has played little or no part in our thoughts.

A not very inviting discussion has recently taken place relating to the "sheer" cost, whatever that may mean, of electrical energy. There are two views regarding cost put forward by controversialists, and both these views may be taken as correct. One side argues that the cost per unit of electrical energy generated is all important, contending that all other portions of the charge to the consumer are of the nature of constant charges, and fluctuate but little with the number of units supplied. Thus, if the charge to the consumer is 8d. per unit, the prime cost of the unit is 2d., and incidental charges 6d. Now it costs 6d. to distribute one unit, but it only costs 6d. to distribute one hundred units, so that with the increased demand for units the profits should increase according to the prime cost per unit, and not according to outcharge per unit. On the other hand, the consumer and the shareholder deride the future, and prefer a certain advantage in the present. They look simply at the balance-sheet, which shows a certain expenditure and a certain income. This expenditure has been increased by the production and the distribution of a certain number of units. According to these views, dividing the total expenditure by the number of units sold gives the prime cost per unit. As we say, both people are right. We are among those, however, who contend that the electrical engineer is not concerned with the consideration of the prime cost from the shareholders' point of view. His chief object is to keep the cost of generation at the lowest possible point, and to distribute to the consumers as great a percentage of the energy generated as possible. The other part of the business lies with the management. It will be seen, then, our view is that the engineer's responsibility ends at the house terminals, not at the dynamo terminals; and, if we mistake not, some engineers prefer to argue as if their responsibility

ended at the dynamo terminals. A misfortune in connection with cost is the persistent iteration of comparative figures of electricity *v.* gas. Many electrical engineers promise their customers or lead them to expect the electric light shall be maintained as cheaply as gas. It may be so in the millennium, but not now, unless there be a mental reservation as to the prices of gas meant. There is usually another reservation that, unlike gas—which the servants light and leave burning all the evening—the electric light is to be switched on and off just when and where wanted. We have pointed out again and again that if what the popular mind takes as meaning as "cheap as gas" is so in reality, electricity would really be about half the price. That is, if gas and its equivalent in electricity cost 4s., the real cost of the electricity to the consumer would be far less than the real cost of gas. There is no getting out of the fact that the indirect expenditure due to gas lighting often costs as much, if not more, than the gas itself, so that the cost of gas does not end with the payment of the gas bill. With the electric light it is different. The indirect payments are absent. And if these payments are not taken into consideration by business men, it is the fault of the exploiters of electric lighting.

THOS. BARRACLOUGH AND CO., LIMITED, Globe Works, Rochdale-road, Manchester, report a large and increasing amount of business during 1891 in the manufacture of their specialities. In the past year they had a larger turnover than in any preceding, and although they worked overtime the whole year, and for a portion of it worked day and night, they were not able to keep pace with the increasing demand for machinery. They have added materially to the number of their tools, and are now completing a new erecting shop with an additional 10-ton travelling crane, in order to facilitate the manufacture of heavy machines. Last year they completed the installation of the large submarine cable factory in Calais, consisting of six machines for making deep-sea cables, one machine for making intermediate cables, and one machine for making shore-end cables of the heaviest description. The two latter machines are each driven by a pair of independent steam engines. In addition to this they made the whole of the core-serving and accessory machinery. The company is now engaged in executing a large order for a new submarine cable works in process of erection in the South of France. They report having executed a large number of orders for electric stranding machines, electric cable machines, indiarubber and gutta-percha machinery, wire-covering machinery, for the United States, Germany, Italy, and the Continent generally. They have introduced in the manufacture of their machinery a number of improvements with the view of enabling the machines to be run at a very high speed with the minimum amount of attendant labour; this involves the making of the machines in the best possible manner. They are now receiving orders and enquiries for machinery from a much wider area than they formerly did. Russia, Spain, Portugal, the Australian colonies, and even China are now manufacturing electric wire and cables, and there is a prospect of the trade spreading yet further. They undertake the fitting up of cable factories with every requisite from the motor to the largest machine made. As a proof of the heavy character of some of the work recently done, they inform us that they have made several machines weighing each from 48 tons to 50 tons.

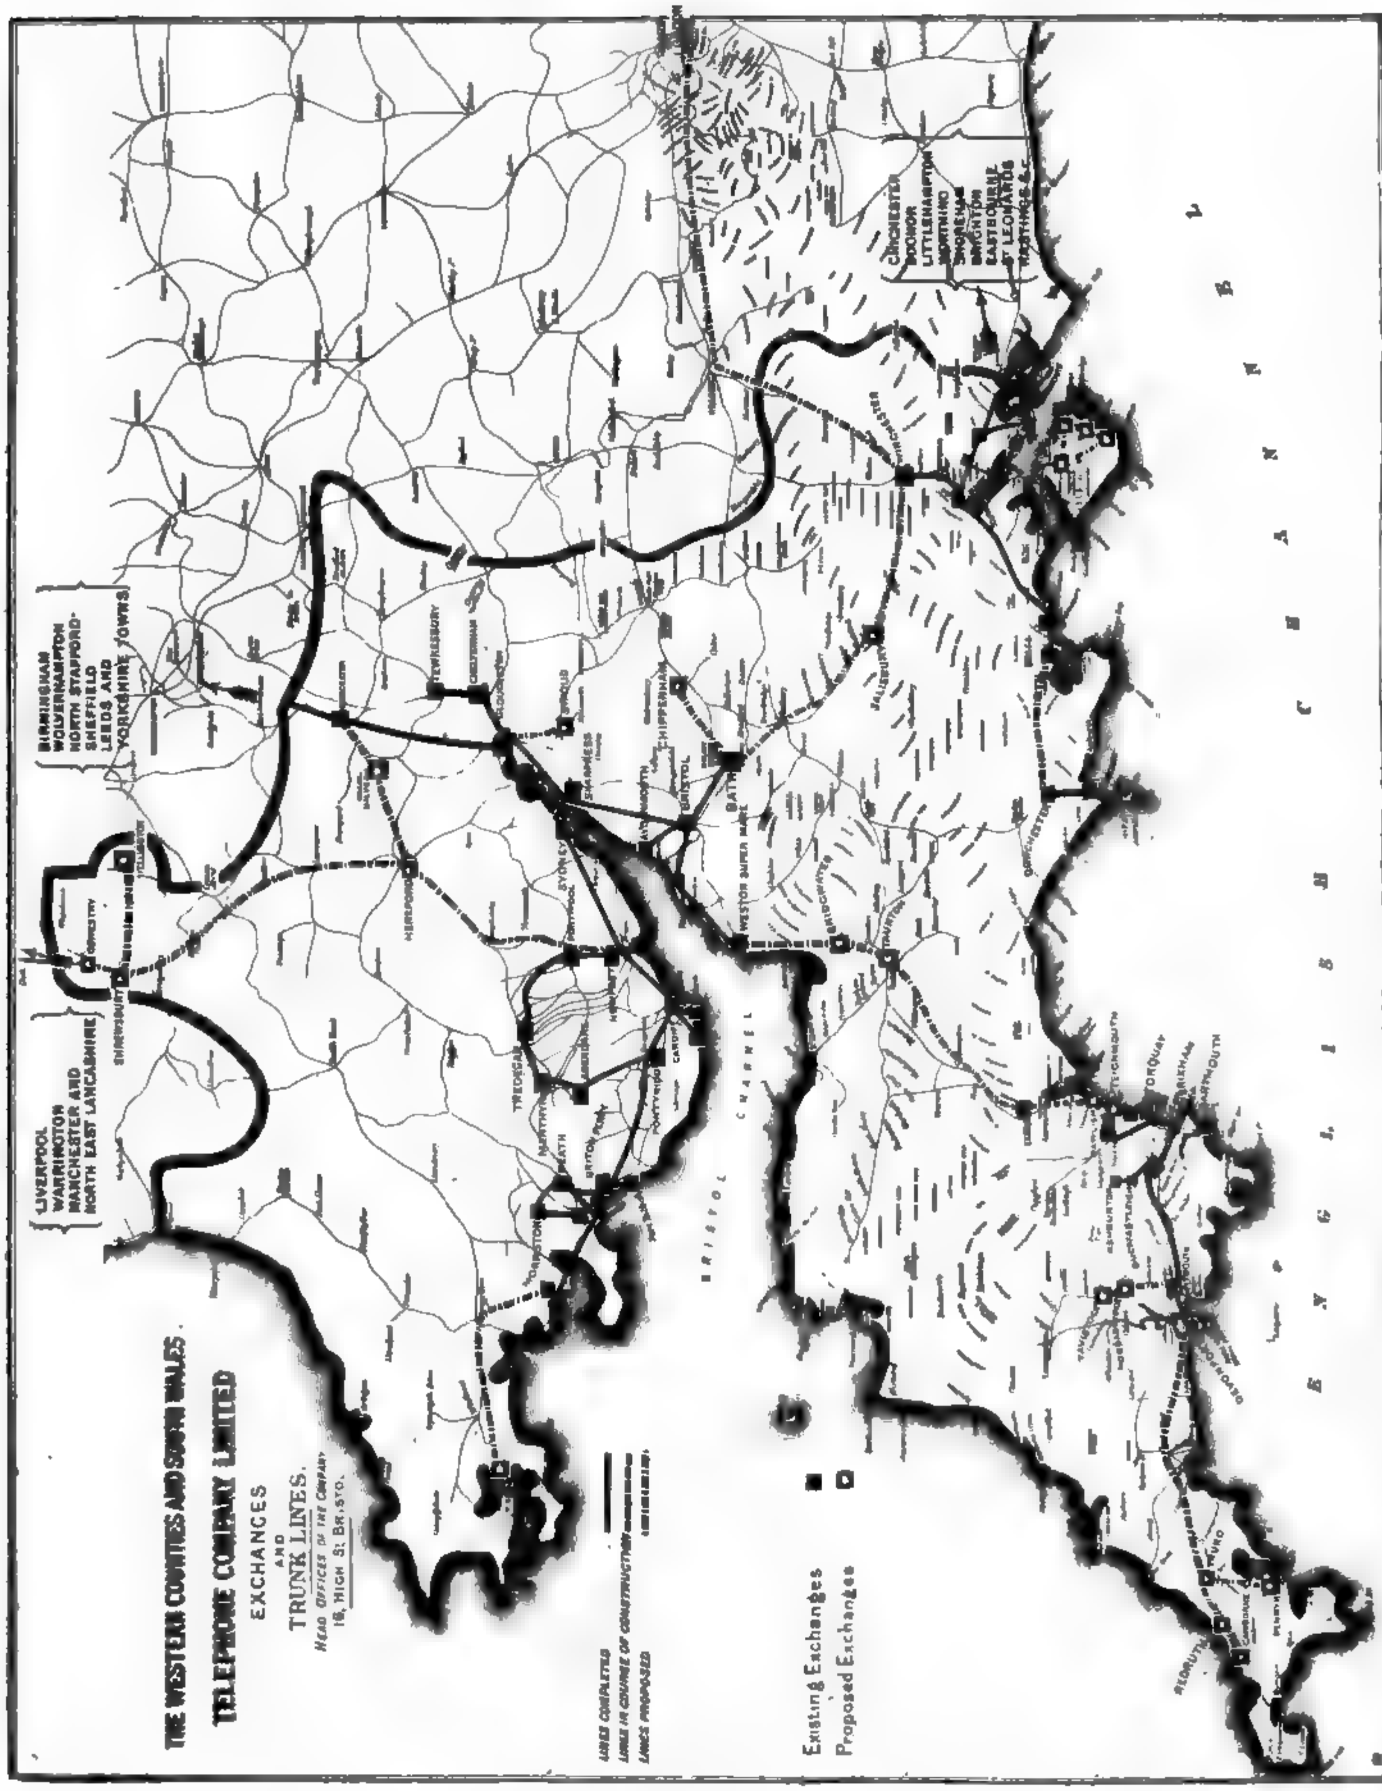
W. T. GOOLDEN AND CO.—The progress of business in the past year has been favourable, the firm having experienced considerable activity in all branches of work, including the supply of dynamos, instruments, and accessories for central station work, and the supply and fitting up of electric installations in private houses and mansions, worked by steam and water power. They have also been very busy with the electric mining work, including plants for pumping, hauling, winding, rock drilling, and coalcutting. Motor work for workshops, launches, etc., has also been fairly good. The prospects for the coming year appear to be fairly good.

JAMES MACINTYRE AND CO. are makers of porcelain only for the use of electrical engineers. The trade is undoubtedly increasing as far as this firm is concerned, and they find it difficult, particularly at this time of the year, to keep pace with the demand for switches, ceiling roses, and the like. Much more care and consideration is being given to the decoration of these articles, many of which are now of an elaborate and artistic character. Perhaps the greatest improvement in porcelain is the tapping of holes to take British Association threads; by this means the small brass attachments are screwed direct into the porcelain, thus avoiding the nut at the back, and therefore improving insulation considerably.

SWINBURNE AND CO.—This firm reports that their business in transformers has largely increased during the past year. They find the demand for their type of transformer gradually growing both at home and abroad. During the year they have also brought out alternating-current condensers, as many engineers thought the exciting currents of their transformers would give trouble. Except with station engineers, who still think an idle current means power, the trouble has never come up in practice; but there has been some demand for condensers, as there is a great deal of experimental work on motors and other apparatus involving them. They have also brought out alternating-current gear for testing cables under high pressures. They are now making a plant to give 40,000 volts and three amperes for the Silvertown Company, who wish to test cables by the mile under high pressures. Messrs. Swinburne and Co. are now bringing out specialities in instruments for central station work—their wattmeter for transformer testing having been already described in this journal. They have introduced a practice which should not be new in transformer business, but is novel—keeping a large stock ready for delivery. They say that more of their increased business is due to this than to theoretical efficiencies of the highest order.

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY, LIMITED; head office, 16, High-street, Bristol. Under the energetic and able management of Mr. H. F. Lewis, this company continues to make good progress in its district. How large this is and how far it has been exploited will be seen from the accompanying map showing the lines completed, in course of construction, and proposed. In December, 1891, the number of exchanges was 46, and the number of exchange private and trunk renters, 4,066. The following is a list of the exchanges open: Bristol and Clifton, Bath, Weston-super-Mare, Gloucester, Cheltenham, Tewkesbury, Newport, Cardiff (two exchanges, connected by local trunks),

Barry, Penarth, Pontypool, Pontypridd, Aberdare, Merthyr, Tredegar, Swansea, Neath, Briton Ferry, Port Talbot, Morriston, Llanelly, Shrewsbury, Worcester, Plymouth, Devonport, Mutley, Torquay, ampton, Winchester, Weymouth. The company has 313 employés. It has an extensive trunk line system at present in three groups—viz.: (1) Bristol, Bath, Weston-super-Mare, Gloucester, Cheltenham, Wor-



Newton Abbot, Paignton, Totnes, Brixham, Dartmouth, Buckfastleigh, Ashburton, Exeter, Portsmouth (two exchanges, connected by local trunks), *Boscombe*, Christchurch, Bournemouth, Poole, Southcester, Newport, Pontypool, Cardiff, Penarth, Barry, Pontypridd, Aberdare, Merthyr, Tredegar, Briton Ferry, Port Talbot, Morriston, Neath, Swansea and Llanelly with each other, and also

with Birmingham and Wolverhampton, and other Midland towns of the National Company's district. (2) Plymouth, Plympton, Ivybridge, Totnes, Paignton, Torquay, Newton Abbot, Brixham, Dartmouth, Buckfastleigh, and Ashburton. (3) Portsmouth, Southampton, Winchester, Bournemouth, and Poole. The above comprises 500 route miles, and 2,330 miles of wire. Exeter is on the eve of being included in No. 2 group. The lines to that city from Torquay will be completed this month. The number of communications on the company's trunk lines have increased from 284,886 in 1888 to 550,500 in 1891, and, taking the latter year as an instance, the trunk communication between towns only averaged 1½d. each. From Weston-super-Mare to Worcester, all within the company's district, is 150 miles by the route taken. The following statistics will be interesting:

TELEPHONIC COMMUNICATIONS OR MESSAGES.

	1885.	1886.	1887.	1888.	1889.	1890.	1891.

Total	1,193,334	1,942,044	2,866,102	4,194,742	5,333,452	6,543,488	7,155,500*
Gr'ss revenue for the year	£2,730†	£9,914	£15,569	£21,845	£26,803	£32,837	‡

* Month of December, 1891, estimated. † 16 months. ‡ Accounts not completed.

Wire mileage on 31st December, 1890.—Exchange and private lines, 2,836. Trunk lines, 2,182. Total, 5,018 miles.

The company has erected a signal station at Rame Head, which is a prominent point seven miles from Plymouth, and is the nearest land to the Eddystone Lighthouse. This they have connected with their Plymouth and Devonport exchange system, and they hope to open this signal station for signalling to and from ships passing up and down Channel, or entering or leaving the port of Plymouth, this month. The Plymouth exchange is connected with the post office in that town by telephone, and arrangements are being made with the Post Office by which telegrams can be received at Plymouth and telephoned to Rame Head and thence signalled to ships or *vice versâ*. The station will be open continuously day and night and Sundays.

SYDNEY F. WALKER.—Mr. Walker writes a characteristic letter, which contains much that some people think but are afraid to say. We give the following extracts: "With regard to work, I have been fairly busy during the year — not as busy as I should have liked—but it has been in my own specialities. London firms, and young firms hailing from nowhere, have been so anxious to secure contracts at something less than cost, if the work was to be carried out properly, that as I could not afford to lose money, nor to do bad work, I am waiting till the clouds roll by for the showy part of the business. So far as I can understand, the present problem in electrical engineering is, not to get work, but to make a satisfactory profit, considering the amount of labour and skill required. What with having to stand by your work, no matter what comes against it, to stand the loss involved by slips of—some other fellow—the little eccentricities usually adopted by electrical engineers when they get a chance to put a spoke in the wheel of a rival, and the cost of tendering, the life of an electrical engineer on his own hook "is not a happy one." With regard to the matter of tenders, I have partly carried out the plan sketched in the article I contributed to your columns. Where a tender involves expense, I do not tender unless within a certain radius of Cardiff, unless I am paid for it, except, of course, in special cases where there is a reasonable hope of return. As a result, the tenders I have given during the year have been much reduced, and my business is considerably healthier in consequence. The cool enquiries one gets at times under the pretence of asking for tenders are exasperating in the extreme. In some cases, it is not too much to say that they are on a level with some of the swindles that are frequently exposed in the papers. A man out of pure curiosity wants to know what it would cost to light his town or village. Another has water power a little way off, steam here, something else there. He is not sure what he wants—doesn't know the power of his fall, what steam he has, or, in fact, anything; but he will condescend to let contractors spend time and money coaching him up in their views, finding out all that he ought to pay an expert for, and finally perhaps he will—*think of it another time*. It never occurs to him that if you asked him and several others to give you, say, a truck load or 1,000 tons of the material he sells, on the chance of your buying some later on, that he would open his eyes very wide indeed. So far as I am concerned, except under the conditions I have named, or in special cases, some other fellow will do the tendering."

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

STEAM ENGINE ECONOMY.

SIR,—It is said by one of your contemporaries in last week's issue, that in a report to the Portsmouth Town Council Prof. Garnett has stated that the Parsons turbo-generator is now "as efficient as the best compound engine of the marine type, and that for light loads it stands unequalled." The authority for these statements is said to be the report by Prof. Ewing, F.R.S., published in your paper for last week.

Those interested in the "best compound engines of the marine type" (as electric light engines) will no doubt take care of their own credit, but the continental users of direct-coupled condensing engines of this pattern will perhaps be surprised to hear that a plant which uses 27·6lb. of water per electrical horse power per hour, when working condensing, is formally stated in a report by the electrical expert of one of the most important English towns to be as efficient as their own.

Our concern is with the statement that "for light loads it (the turbo-generator) stands unequalled." We beg to assure Prof. Garnett that there are no figures in Prof. Ewing's report which bear this out. At low temperatures the turbo-generator is, for obvious reasons, *relatively* a more efficient machine than an expansive steam engine; but at no power quoted (not even at *no* electrical load, at which even an alternating station can hardly want to run) is the consumption nearly so low as that in the best Willans engines with direct-driven dynamos—of course, when the latter were working condensing. At full load the consumption of the turbo-generator reaches, as above stated, to 27·6lb. per electrical horse-power, a figure usually surpassed by the Willans *non*-condensing engine. In many recent trials of a Willans condensing engine (of much smaller power than the turbo-generator tried at Newcastle; in fact, indicating only from 30 h.p. to 40 h.p.) the consumption per indicated horse-power per hour has been about 12·8lb. of steam. With a combined efficiency of 80 per cent., which is the lowest we are accustomed to get with good dynamos, this corresponds with 16lb. per electrical horse-power per hour.

These figures, which are recent, are probably not known to Prof. Garnett, but Prof. Ewing's report speaks of published trials with a Willans engine, in which the consumption was about 25lb. per unit, or, say, 18·6lb. per electrical horse-power. Yet Prof. Garnett totally ignores these figures from an actual engine (compared with which those of the turbo-generator are *about half as large again*), and makes comparison with nothing but an engine of a kind which no one in this country would be likely to use, whereas the Willans

engine is used in England (for central stations) to the extent probably of 2 h.p. for every 1 h.p. of all other kinds of engines put together. Thus in the comparative estimates stated to have been drawn up for the guidance of the town councillors, the cost of an installation of turbo-generators is compared with that—not of Willans engines, or of any other form of direct-driven plant—but with an absurdly obsolete plant, consisting of engines "making not more than 90 revolutions per minute, coupled by endless rope gearing to dynamos making 300 revolutions per minute."—Yours, etc., WILLANS AND ROBINSON, LIMITED.

Jan. 13, 1892. C. S. Essex (Secretary).

OUR PORTRAITS.

Kapp, Gisbert, M.I.C.E., M.I.E.E. Born at Mauer, near Vienna, in 1852; educated at the Polytechnic School n Zurich, where he studied under Zeuner and Kohlrausch, and gained his diploma of mechanical engineer. For some years Mr. Kapp was engaged in purely engineering work, coming into contact with electrical work at the Vienna Exhibition. It was not till 1882 he made his fixed residence in England, having been travelling on the Continent and in North Africa for some years. In 1882, however, we find him engaged with Messrs. Crompton and Co., and he soon began to make his name known in the profession. Since then Mr. Kapp has been connected either in conjunction with others or individually in taking out a number of patents. His name is intimately connected with the development of the dynamo, with compound winding, and with electromagnetic measuring instruments. A large number of exceedingly practical papers have come from his pen, and his work on "Transmission of Power," published by Whittaker and Co., has passed through several editions, and is acknowledged as *the* text-book on the subject. At the present time Mr. Kapp is completing a monograph on "Dynamos, Alternators, and Motors," to be published shortly by Messrs. Biggs and Co. In 1885, Mr. Kapp severed his connection with Messrs. Crompton and Co., and for a period undertook the London editorship of *Industries*. When, however, the principal office was removed from Manchester to London he left the paper, and has since devoted his whole attention to the business of a consulting electrical engineer.

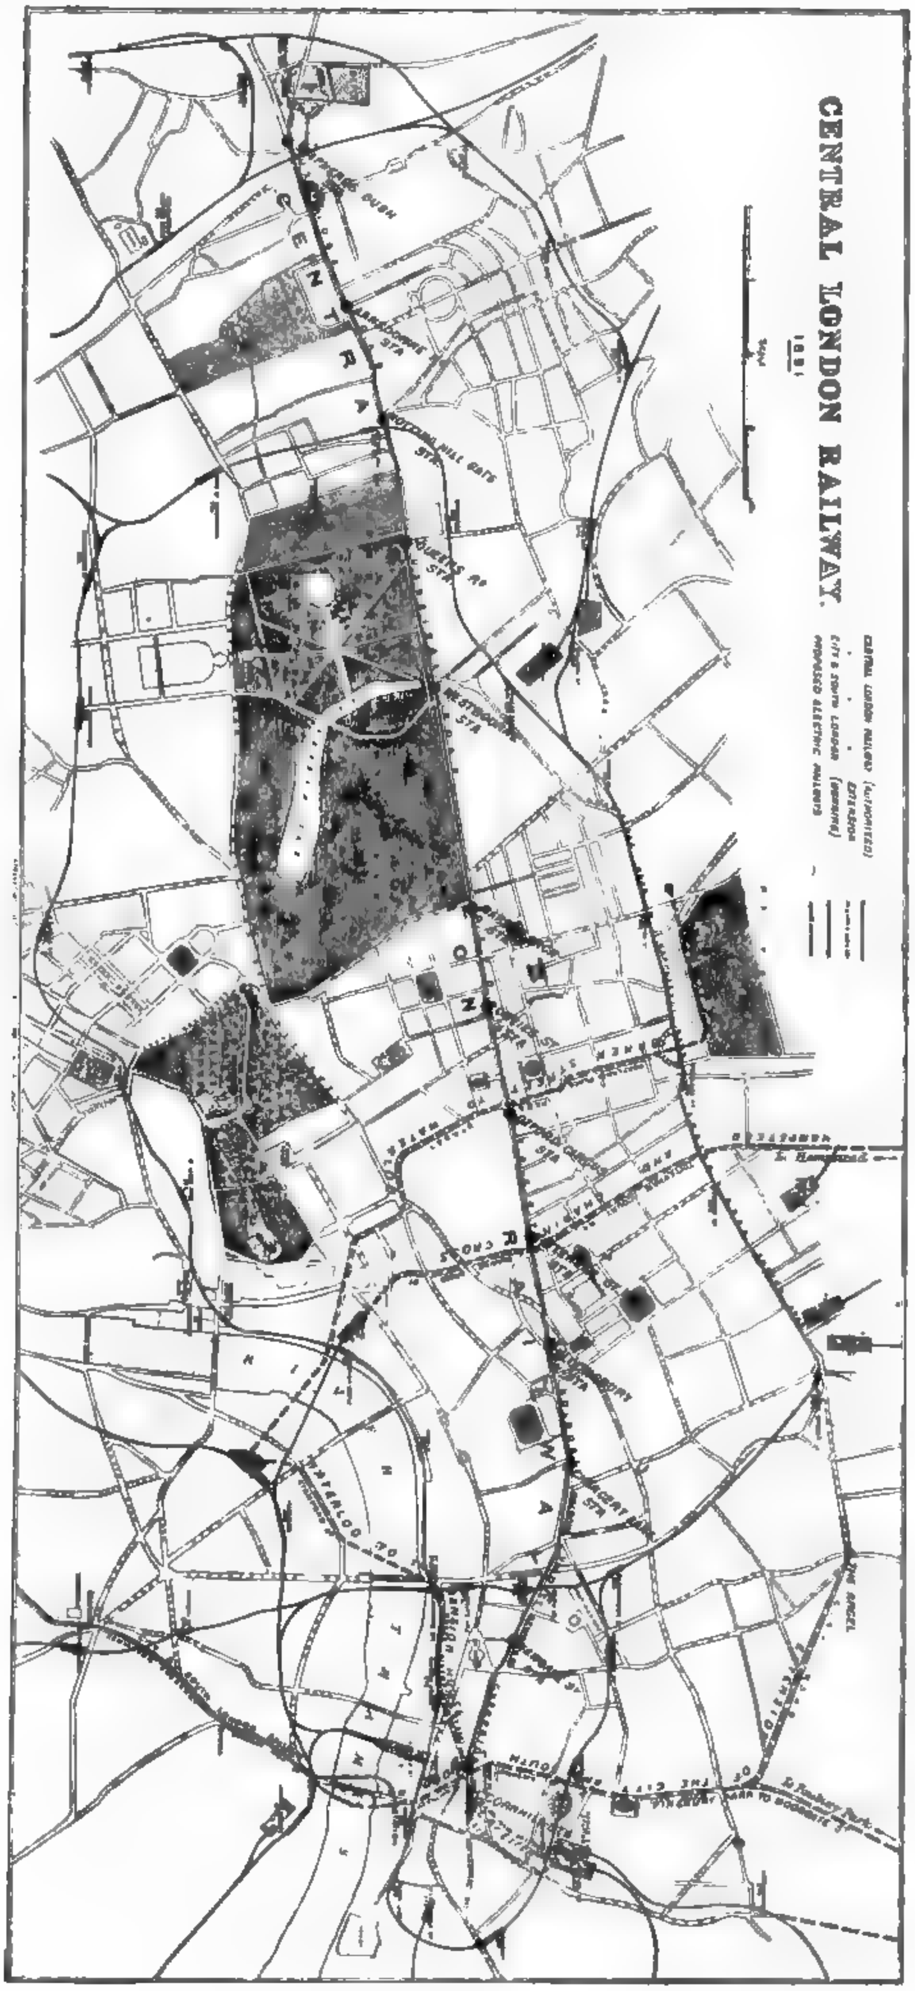
Albright, J. F., C.E., M.I.E.E. Born in Birmingham, 1857; was educated as an engineer, partly at the Crystal Palace Engineering School, and subsequently three years as pupil with the late Sir J. Bazalgette. In the year 1880 Mr. Albright entered into electrical work with the Swan Company at Newcastle-on-Tyne. His first employment was on the "Servia," and afterwards he took charge of the company's exhibits at the 1882 exhibition at the Crystal Palace. For a time Mr. Albright was with the amalgamated Edison-Swan Company, and ultimately took charge of this company's contracting department, a position held till the spring of 1884, when he entered as a partner into the firm of Messrs. R. E. Crompton and Co. When this firm became a limited company, Mr. Albright became managing director. Our acquaintance with Mr. Albright dates back to a time previous to his entering the ranks of the industry, and each step in his career has shown him to possess the true instincts that combine to make a first-rate man of business. We fancy he would be the first to repudiate the view that electrical work necessitated too great a deference to mere theory, but would maintain that practical considerations more often regulate commercial production than do theoretic ones. Quite recently Mr. Albright made what may be called a tour of the world, with a view of opening up new fields for the company's productions, and of extending the branches already existing. Besides his connection with the parent company, he is chairman of the Crompton-Howell Storage Battery Company, and a director of the Crompton Supply Company of Australia.

Gordon, J. E. H., M.I.C.E., M.I.E.E., born in 1852, is the son of the late Dr. J. A. Gordon, F.R.S. He was educated at Eton, King's College, London, and Cambridge, where he took his B.A. degree in mathematics, subsequently working under Clerk Maxwell in the physical laboratory. In 1878 Mr. Gordon accepted the appointment of assistant secretary to the British Association, an appointment, however, which he held only two years, for he soon became interested in the construction of dynamos. The outcome of this work was his dynamo constructed by the Telegraph Construction and Maintenance Company at Greenwich, which paved the way for the Paddington installation, under Mr. Gordon's system. The plant at Paddington was started on April 21st, 1886, and is still at work. It was, however, decided by the company with which Mr. Gordon had been working not to continue electric lighting work, so he made arrangements to form the Whitehall Company, an installation which subsequently formed the nucleus of the Metropolitan Company's undertaking. Mr. Gordon was elected a director of the Metropolitan Company at its formation, afterwards retiring and throwing all his energies into consulting and contracting work. Mr. Rivington joined Mr. Gordon, and the firm registered the business as a company in 1890. Of late Messrs. J. E. H. Gordon and Co. have been very active in installation work. A description of their Carlow (Ireland) installation has been given in this paper, and their latest work at Sydenham, where a fine central station has been built and equipped in a very short space of time for the Electric Installation Company.

Reckenzaun, Anthony, M.I.E.E. Born, and educated, at Gratz in 1852. Like most successful electrical engineers, Mr. Reckenzaun was originally trained as a mechanical engineer. Coming to England in 1872, he entered the employ of Messrs. Ravenhill and Miller, afterwards Messrs. Easton and Anderson. While with Messrs. Easton and Anderson he qualified as a teacher under the Science and Art Department, and established evening classes for the employés. Subsequently he attended lectures at the School of Mines, and at Finsbury. Feeling a great interest in electrical matters, Mr. Reckenzaun made a thorough study of the apparatus at the Paris Exhibition in 1881, then joined the Faure Company, but soon after accepted the position of electrical engineer to the Electrical Power Storage Company. Here he turned his attention to traction, a branch of the industry with which his name has since been intimately connected. Storage batteries have also been carefully studied, and their capabilities investigated. In fact, Mr. Reckenzaun has perhaps done more than anyone to show, by his practical work, and by various papers, the value he places upon storage batteries in all kinds of electrical work. He spent a year or so in America, successfully fighting the fight of such batteries. More recently he has been closely allied with Mr. Binswanger, with the Keys' Company, and, lastly, with Messrs. Greenwood and Batley. Mr. Reckenzaun has reached his acknowledged position as one of our foremost experts in batteries and traction, because of the painstaking industry and skill with which he investigates every problem connected therewith.

Gray, Robert Kaye. Born 1851, in Glasgow. Educated at the Greenock Academy, University School and College, London, and in Paris. In 1869 Mr. Gray was on the staff of the late Sir Charles Bright in the capacity of a telegraph engineer, and was employed in the West Indies. In 1871 he transferred his services to the India Rubber, Gutta Percha, and Telegraph Works Company, acting as engineer and electrician. He has remained with the company ever since, gradually rising to the post of engineer-in-chief. Since he has been with the company Mr. Gray has taken part in a number of cable-laying and repairing expeditions in the West Indies, and on the coasts of North and South America. In this connection we may mention that the "Dacia," one of the India Rubber Company's cable ships, was fitted throughout with electric light so far back as 1879. We believe that she was the first ship to be completely lighted in this way. Of late years, Mr. Gray has not been so intimately connected with the engineering branch of cable enterprise, or, in fact, any electrical work, as with the management of the business operations connected with the direction of cable and other companies of the boards of which he is a member.

CENTRAL LONDON RAILWAY.



The accompanying map will show our readers the magnitude of the proposed work, and the district it is intended to serve. There is no doubt that the traffic in London is of vast magnitude, and that the opening up of new routes gives little or no relief to the old ones. In fact, the traffic seems to increase quite as fast as new routes are opened. The Exploration Company, which has taken the initiative in this proposed work, has endeavoured to educate the public and to explain its views by issuing an admirable map with descriptions of the railway. From their map the one given by us has been prepared. An examination of it will show the proposed depôt at Shepherd's Bush, and the various stations, taking them in order from the depôt, show the direction the line will take. Thus we have Shepherd's Bush, Lansdowne-road, Notting Hill Gate, Queen's-road, Westbourne, Marble Arch, Davies-street, Oxford-circus, Tottenham Court-road, Bloomsbury, Chancery - lane, Newgate-street, Cornhill, with an extension to the Liverpool-street Station of the Great Eastern Railway. There is a vast population to be served by such a line, and we cannot see any reason, if the matter be managed with a due regard to economy in construction, why this line should not be eminently satisfactory. It is proposed to work it electrically, thus obviating many of the troubles which arise from the use of steam. But we shall have much more to say on the scheme at a future date. Meanwhile, the map, as we say, will tend to show what is the intention of the promoters. It also indicates the route proposed to be taken by the other underground railways for which Bills have been deposited in Parliament. Thus we have the Baker-street to Waterloo line; that which is to run between Hampstead and Charing Cross; the Waterloo and City line; and the City and South London extension to The Angel, Islington. It is far from likely that all these schemes will be passed during the ensuing session, but that most of them will become accomplished facts in the course of a few years is more than probable. A railway between North and South London is badly wanted, so is a line between the West and the City, as well as on from Waterloo to the Mansion House.

INDIAN TELEGRAPHS.

From the Government resolution on the report on Indian telegraphs during the past year, it appears that the additions to the system were 1,791 miles of line, 7,373 miles of wire, and 21 miles of cable. At the close of the year there were in operation 37,070 miles, 113,512 miles, and 251 miles of line, wire, and cable respectively; 168 new offices had been opened during the year, bringing the number to 3,103. The gross receipts for the year, including State-paid messages, amounted to 68,28,855 rupees, and working expenses to 46,88,802 rupees, showing a profit equal to 4·126 per cent. on the capital outlay. The receipts from telegraphic money order advices have steadily risen from 46,000 rupees in 1888 to 84,000 rupees in 1891. During the year excellent work was done by the Department in laying field telegraph lines. The Sikkim line was maintained, as also that in the Chin country. A new line in the Assam section of the Chin-Lushai country was laid for a distance of 59 miles, through a most difficult and unhealthy country. The working parties suffered severely from sickness, one officer losing his life and another being invalided. For the Hazara expedition 182 miles of extra wire had to be laid to connect Hussan Abdul and Abbottabad with the bases of operation at Derband and Oghi, and from those points onwards 103 miles of field wire were laid and 15 offices opened. The receipts of the telephone companies at Calcutta, Madras, Bombay, Kurrachee, Moulmein, and Rangoon show a small increase of 10,657 rupees, while the number of subscribers is now 1,004 against 961 in the previous year. The charges per word between India and the Straits Settlements have been reduced, partly by reductions in the Indian terminal and transit rates, and partly by reductions in the Eastern Extension Company's rates. The transit rate claimed by India for messages passing between Europe and the Far East was largely reduced. By the connection of the French lines in Tonquin with China, a new and cheap route for messages to the latter country *viâ* Siam has been opened.—*Times.*

NEW FLEXIBLE METALLIC TUBING.

A new kind of tubing, of interest to steam power users and electrical engineers, is being manufactured by the Flexible Metallic Tubing Company, of 48, Parker-street, Holborn, W.C.

The tubing is flexible, and is made in a machine from metal strips of the necessary length, width, and thickness, according to the purpose for which it is required. In passing through the machine the strips, which are of steel, galvanised steel, or otherwise, have formed upon one side two corrugations in a longitudinal direction, one being large and the other small. The corrugated strip is then coiled in the form of a spiral round a mandrel, this operation being so performed that the small corrugation enters the large corrugation and interlocks with it. This forms what is known as a piston joint. The tubing, which is unaffected by ordinary liquids or gases, has been tested both at high and low pressures—steam up to 60lb. and hydraulic up to 1,000lb. to the square inch. The tubes are made from $\frac{5}{16}$in. to 3in. internal diameter, and plant is now being laid down for the manufacture of tubes up to 12in. diameter. This kind of tubing is now in use for a variety of purposes, including for gas and steam pipes, compressed air, speaking tubes, and also as sheathing for electric light cables, whilst it can likewise be used for running ordinary house leads. A special type of coupling, which will not give way under the pressures mentioned, is used for joining lengths of tubing.

A Chance for Amateurs.—An idea that is worth consideration and imitation has been started at Chicago to induce all the amateur electrical societies to combine in making a united exhibit at the exposition. It is quite possible that among much "tinpot" electrical inventions something really good and useful might be discovered.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

II.

(Continued from page 17.)

UNITS, *continued.*

Ohm, continued.—In addition to the foregoing recognised values of the unit of resistance, a new value has recently been proposed by the Electrical Standards Committee appointed by the Board of Trade.* Its value is equal to the resistance of a uniform column of pure mercury of 1 square millimetre section, and 106·30 centimetres long, at a temperature of 0deg. C., this being taken by the Committee as most nearly approaching the absolute theoretical value of the unit. It will probably be known as the Board of Trade or the Imperial Ohm, and is likely to be made the legal unit of electrical resistance for this country by an Order in Council under the Weights and Measures Act. In order to show the relation of this unit to the various others given in Table 1, page 17, of the issue of 1st January, we reproduce this table below, with the Board of Trade Ohm included in it.

TABLE 1.—RELATIVE VALUES OF THE VARIOUS "OHMS."

Description of "Ohm."	Length of mercury column 1 sq. mm. section and at 0° C.	Values expressed in terms of		
		B.A. Ohm.	Legal Ohm.	True Ohm.
	Centimetres			
Siemens Ohm	100·00	0·9541	0·9435	0·9411
B.A. Ohm	104·82	1·0000	0·9889	0·9864
Kohlrausch Ohm ...	104·93	1·0010	0·9899	0·9874
Legal Ohm	106·00	1·0113	1·0000	0·9975
True Ohm...............	106·27	1·0139	1·0026	1·0000
Board of Trade Ohm	106·30	1·0141	1·0028	1·0002
"Baltimore" Ohm..	106·34	1·0146	1·0033	1·0006

Volt.—The fundamental definition of the unit of Electrical "Pressure," Difference of Potential, or Electromotive Force (usually written E.M.F.), the *Volt*, is the Electromotive Force which is generated in a conductor when it is made to cut across magnetic lines of force at the rate of one hundred million (10^8) per second.

Unit Electromotive Force can also be defined in terms of the units of Resistance and Current, thus: One *Volt* is that Difference of Potential which must be maintained between the two ends of a conductor whose resistance is one Ohm, in order to keep a current of one Ampere flowing steadily through it.

The E.M.F. of a newly made-up Daniell cell is about 1·1 Volt, and that of a Latimer Clark standard cell varies from 1·471 to 1·435 Volt with a range of temperature of 0deg. C. to 32deg. C.

Ampere.—The unit of Rate of Flow of an electric current, the *Ampere*, is that current which will flow through a wire having a Resistance of one Ohm, when a Difference of Potential or Electrical "Pressure" of one Volt is maintained between its two ends.

A current of one Ampere will deposit in one hour 1·174 grammes or 18·116 grains of Copper in a copper electrolytic cell, and 4·074 grammes or 60·52 grains of Silver in a silver electrolytic cell; and will decompose 0·3357 grammes or 5·180 grains of slightly acidulated water in the same period.

Ohm's Law.—It will be observed that the second definition of the Volt, and the definition of the Ampere are merely two different statements of the same thing; and the Ohm could also be defined in precisely the same terms. All these are simply statements from different points of view of the well-known Ohm's Law, which in its simplest form may be shortly stated as follows:

The current in Amperes flowing through any conductor is equal to the difference of potential in Volts between any two points in this conductor, divided by the resistance in Ohms between these two points.

* See *Electrical Engineer*, September 11th, 1891, page 262.

Thus, if C be the current in Amperes flowing through any circuit;
E the difference of potential in Volts between any two points in it;
and R the resistance in Ohms between these two points; then

$$C = \frac{E}{R};$$
$$E = CR;$$
$$\text{and } R = \frac{E}{C}.$$

This law was originally enunciated by Ohm in the year 1827 as the result of a series of experiments carried out by him, and it has since been verified by investigations made at the Cavendish Laboratory in Cambridge.

Watt.—The electrical unit of Power, or rate of doing Work, the *Watt*, is the electrical unit which corresponds to the mechanical term Horse-power, of which it is simply a sub-multiple. The power transmitted by the current, or the energy developed in the circuit, when a current of one ampere flows through a conductor whose resistance is one ohm, is termed one Watt.

1 watt is numerically equal to 1 ampere × 1 volt;
or if C represents the current in amperes,
E „ „ electromotive force in volts,
R „ „ resistance in ohms,
and W „ „ power in watts,
in any circuit; then

$$W = C \times E; \text{ and from Ohm's law}$$

we may write $$W = \frac{E}{R} \times E = \frac{E^2}{R},$$

and $$W = C \times CR = C^2R.$$

Expressed in terms of the mechanical unit, one watt is = $\frac{1}{746}$th of a horse-power,

$$= \frac{33{,}000}{746} = 44 \cdot 25 \text{ foot-lbs. per minute.}$$

Thus, if a current of C amperes is flowing through a circuit whose resistance is R ohms, the total difference of potential being E volts, then the power developed in that circuit is =

$$\left.\begin{array}{l} C \times E, \\ \text{or } \frac{E^2}{R}, \\ \text{or } C^2R \end{array}\right\} \text{Watts;}$$

$$\left.\begin{array}{l} = \frac{CE}{746}, \\ \text{or } \frac{E^2}{746\,R}, \\ \text{or } \frac{C^2R}{746} \end{array}\right\} \text{Electrical Horse-power.}$$

Joule.—The electrical unit of Work or Energy, the *Joule*, expresses the work performed, or the heat liberated, in one second when a current of one ampere is forced through a conductor whose resistance is one ohm; or, in other words, one Joule represents the work done per second in a circuit in which a power of one Watt is being developed.

Thus, if in addition to the quantities represented in last paragraph,
J represents the energy in joules,
and T „ „ time in seconds,
then

$$J = WT,$$
$$= CET,$$
$$= \frac{E^2T}{R},$$
$$= C^2RT.$$

One Joule is equivalent to $\frac{33{,}000}{746 \times 60} = 0{\cdot}7373$ foot-lbs.

Coulomb.—The unit of Quantity of Electricity, the *Coulomb*, is the quantity of electricity carried in one second past any cross-section of a conductor through which a current of one ampere is flowing. An ampere is therefore equal to a coulomb per second, or a coulomb is equal to an ampere-second.

Thus, writing Q for the quantity of electricity in coulombs, and taking the other values as in the last two paragraphs, we have

$$Q = CT,$$
$$= \frac{ET}{R}.$$

The coulomb is chiefly used in connection with electro-chemistry.

(*To be continued.*)

ELECTRIC DRILLS.

The portable electric drills with flexible driving shafts, made by MM. Sautter, Harlé, and Cie., illustrated herewith, have been used in considerable numbers in ship-building yards, arsenals, and boiler works. They are equally serviceable in large works for the construction and erection of bridges, mining work, the construction of railway lines, and so forth. It may be said that their use is advisable in any case where it is easier to mount the tool on the work than to take the work to the tool. Further, this machine tool is capable of being used not only for wood and metal drills, but with other machine tools and polishing brushes.

MM. Sautter, Harlé, and Cie. have made these electric drills part of their regular manufacture. The following are particulars of these tools given in the *Revue Industrielle.*

Every installation of this kind comprises essentially a dynamo, one or several electromotors to which the tools are adapted by means of flexible shafting, and the necessary conductors leading from dynamo to the motors. The conductors are generally supported by porcelain insulators fixed on poles at distances of 30 to 50 yards. The dynamo is fixed at the centre of distribution, though sometimes the dynamo used for lighting is used concurrently for the transmission of power. The electric pressure varies according to circumstances, usually between 50 and 120 volts; that of 70 volts is most ordinarily used. Connections which are easy to make and unmake lead the current by means of insulated twin wires to electromotors which drive the machine drills by the intermediary of flexible shafting.

Figs. 2 and 4 represent the arrangement adopted by MM. Sautter, Harlé, and Cie. These are of two types. The dimensions of the smaller model are shown in the illustration. The following are the further details of this type, and of the larger one:

No. of revolutions per minute of the motor	2,000	2,000
„ „ „ of the shafting	475	450
Power in watts absorbed	700	1,100
Weight	68lb.	103lb.

As is seen, the angular velocity in revolutions per minute of the motor is very greatly reduced in the tool itself by spur gearing.

In the special case of the application of electric drills to shipbuilding, MM. Sautter, Harlé, and Cie. have worked out a convenient system of conductors by means of copper strips, F, fixed on boards run the length of the ship in construction; drums or posts, E, capable of carrying a certain length of twin conductor, D (Fig. 1), are fixed to supports with double contacts pressing on the copper strips, from which the current is drawn as desired.

In the usual case where overhead conductors are used, or in special cases for shipbuilding, the twin conductors, D, of 12 or 15 yards length, are terminated by a connecting plug, which can be inserted in one of two holes arranged for this purpose in a regulating resistance-box, R, which is furnished with a hand commutator. In the second plug-hole is inserted the plug attached to one end of the twin wire, G, four or five yards long, the other end of which is attached to the terminals of the motor.

The resistance is used to regulate the difference of potential necessary at the terminals of the motor according to the work in hand. It is also used to prevent the motor overrunning when running light.

The conductors are furnished with fuses at the dynamo end, and at each branch. This avoids the burning of insulation, or fear of the belt coming off in cases of accidental contact of the conductors. Near the dynamo is usually a switchboard with ampere-meter, voltmeter, cut-outs, and field-magnet resistance, etc. Certain of the accessories,

such as cut-outs, field-magnet resistances, measuring instruments, and so forth, are not indispensable, but are always advisable in an installation of any importance.

A clamp suitable to each special case serves to fasten the tool-carrier, P, on the piece of work to be drilled, B. The connection of motor to tool is easily made by means of the flexible shafting, the motor standing on the floor or in any convenient position. The feeding of the drill is brought about by hand by the movement of the wheel, C,

In actual work the flexible is kept from too sudden curves, more particularly in the vertical direction, as the weight of the flexible tends to loosen coupling-piece at the motor, and to separate the leather sheath from the threaded socket. It sometimes happens that the cores of the flexible shafting break at the extremities, near the sockets to which they are welded. These breakages occur generally at the moment the hole is pierced through, or when in piercing several sheets of iron superposed, the tool bites.

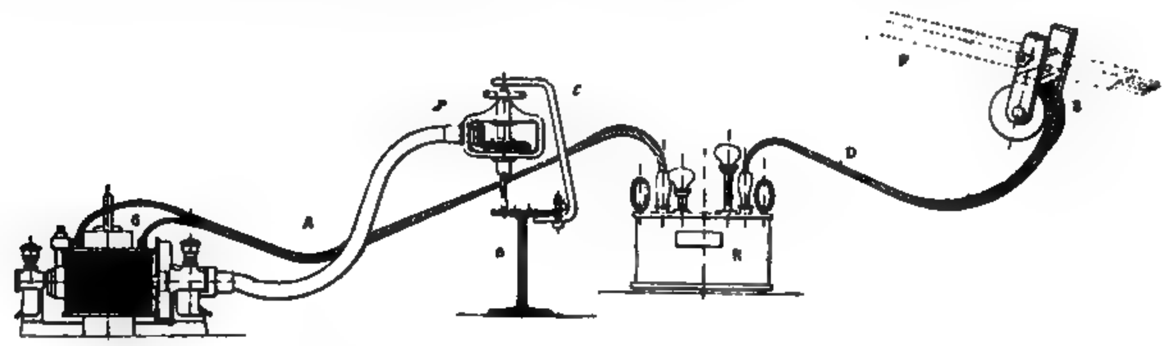


Fig. 1.

mounted on a threaded axle. A movable resistance stand, with a wheel handle switch, gives complete control of the gradual starting and stopping of the motor, and to some extent of its speed.

The difference of potential (constant at the dynamo) and the strength of current vary with the size of drill, depth of working, nature of the metal, and pressure exerted on the tool. The rheostat contacts are numbered 0 to 4, and the various movements can be made with surety and the avoidance of arcing at the contacts.

For iron and soft steel the tangential velocity of the drill may be regulated by means of the rheostat at about 10 cm. (3⅞in.) per second, and the pressure exerted by means of the screw should be such that the feed is about $\frac{1}{10}$ mm. per revolution of the tool. For drills above 28 mm. to 30 mm. (1¼in.) it is well to substitute worm gearing for spur gearing. The core of the flexible shafting and the worm gear should be preferably lubricated with thick grease from mineral oil. Such drilling should be carefully done by screwing the feed very gradually. The core is repaired in the following way: The portion of the metallic core remaining in the socket is first detached; the broken steel wires are then neatly cut with a metal saw, after having bound them together of the section required, and the end of the core is then strongly brazed; this is then filed up to a conical shape, fitting the inside of the socket. The faces of both are carefully washed and wiped several times to remove all trace of dirt or acid. The core is then tin-soldered firmly to the socket, having taken care again to remove all acid to avoid oxidation of the wires. If a breakage occurs at any other part than at the ends, repair is impossible. With workmen used to the management of the tests breakages become rare.

The following table gives the results of several tests made upon an electric drill in the service of the Control of the Marine.

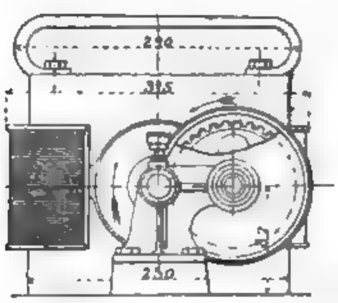

Fig. 2.

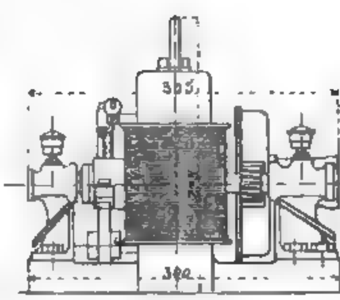

Fig. 3.

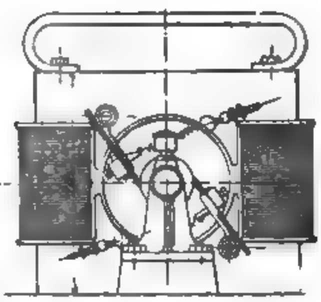

Fig. 4.

It is best to use helicoidal bits or drills with very wide edges, and to take care not to put too much pressure on the feed.

The following table gives some particulars of the flexible shafting and the tool-carriers.

Flexible Shafting.			Drill	
Maximum diameter of holes pierced soft steel.	Normal length of flexible.	Number of revs. of flexible.	Average number of revs. of tool. Spur gear.	Worm gear.
10 to 20 mm.	6ft.	550	140	—
20 to 30 ,,	6ft. 9in.	475	105	[illegible]
30 to 40 ,,	6ft. 9in.	450	90	45
40 to 55 ,,	6ft. 9in.	400	[illegible]	27

These flexible shafting are of the type employed in the French navy, and are of French manufacture, M. Foureau having introduced them from America. The details of the construction were given *Revue Industrielle*, Oct. 11, 1890.

It is well to add that the pressures on the tool may be notably increased when the drill is working intermittently—the progress is then much more rapid.

—	Drill with helicoidal bit 28 mm. (1⅛in.)			Drill with helicoidal bit 36 mm. (1⅜in.).		
Nature of metal	soft Siemens-Martin steel					
Pressure in pounds on the tool	528	704	704	176	528	528
State of bit	new	sharp'n'd	good	good	new	fair
Time required to drill holes 1in. deep..... ...	4′ 30″	9′	4′	30′	3′ 15″	6′
Volts at terminals of motor	68	65	65	50	68	65
Current in amperes......	10	10	10·5	10	15	14
Energy expended in watts	680	650	682	500	1,020	910

Speaking generally, the figures given in this table show that the energy expended and the duration of the work vary according to the sharpening of the bit and the pressure exerted upon it. These differences may become

more accentuated when working upon different metals, the other conditions remaining the same.

Ordinary workmen, and even labourers, very rapidly are able to make good use of the electric drills. Practice has shown that the relation between the two sets of tools one working by hand with ratchet brace, and the other with electric drill, is as one to five or six; the quality of the work is at least equal to that of handwork. These observations, made many times by the managers of workshops, serve to indicate the usefulness of these kinds of machine tools.

GLASGOW.

At the meeting of the Council last week the question of the working of the tramways by the Corporation arose for discussion, about which the following information may be found interesting as giving some idea of the views being taken by the Council. One minute of the Tramway Committee reads that: "A sub-committee met with a deputation from the directors of the tramway company, consisting of Messrs. Young, Reid, Faill, and Pettigrew, with Mr. Duncan, secretary and manager, and Mr. Boyd Anderson, law agent. The chairman explained at once to the deputation that the sub-committee had had the company's letter before them, but that the sub-committee have no power to do anything further than to endeavour to make arrangements with the present lessees for the acquisition of their stables and plant, or such portions thereof as may be necessary for carrying on the working of the tramways on the expiry of the lease. The deputation urged that they should be informed what lines the Corporation propose to commence to work on the expiry of the lease by mechanical haulage. The sub-committee, in reply, informed the deputation that they were of opinion that the subject of the request has no relevancy to the matter which the sub-committee are now prepared to discuss with the deputation, but that in any case the sub-committee are not in a position to give the information, as no resolution on the subject has yet been come to. The deputation thereafter urged that till this is arranged the question of the transfer of the company's stabling and plant should be left over. They were informed, however, in reply, that any arrangement on this latter point must be come to without delay, so that the Corporation may know what stabling, car-sheds, and other working plant they will require to provide themselves. After considerable conversation, the deputation agreed that they would consider what portions of their stabling and plant they would be willing to sell to the Corporation, and would submit an offer of it to the committee for their consideration."

Another and subsequent minute reads: "The sub-committee appointed to prepare a statement showing the comparative cost of working tramways by the various methods of haulage, reported that they had considered the remit and the offers submitted by the General Electric Power and Traction Company, Limited, and by the Electric Storage Company, for working cars on the accumulator system, and that adding thereto such other items as seemed necessary to bring the whole cost of working by that system on a parity with the cost of working by animal power, they found there would be a saving of about 1d. per car mile run on the former as compared with the latter system. There was submitted a communication, dated 22nd inst., from the Tramway Company, making proposals whereby the Corporation might, if so desired, acquire the whole of the properties and plant used by the company in conducting the tramway portion of their business, or only certain specified portions thereof. These proposals were remitted to a sub-committee, consisting of Bailies Paton and M'Farlane, Councillors Colquhoun, Stevenson, and Wallace, for consideration and report. The sub-committee having considered the remit made to them by the Tramways Committee on 22nd inst., and having heard the town clerk on the report by Messrs. Johnstone and Rankine on the condition of the tramway lines, and as to what and when further renewals will probably be required, resolved to recommend that he be instructed to intimate to the company that the Corporation hold them liable to implement the obligation imposed on them by the lease, to hand over the tramways to the Corporation at the end of the lease in as good working condition as when they were given over to them, or otherwise to pay such sum as will enable the Corporation to put the tramways in that condition. That sum is estimated in Messrs. Johnstone and Rankine's report at £77,759."

Bailie Paton, in moving the approval of the minutes, said there were various matters of great importance in them. First of all, they had the report from a sub-committee in regard to the use of electricity as a motor in place of horses. They had gone very carefully into that matter, and with the assistance of the City Chamberlain they had prepared a careful statement, the result of which was that practically they found the offer they had from the General Electric and Traction Company enabled them to do the working of the cars at 1d. per car mile less than the cost in Glasgow at the present time, and 1½d. less than the cost to the largest company in London at the present time. One penny per mile on the mileage run meant about £18,000 per annum. If they took into consideration, also, that the receipts per mile would be greater, as it had been proved by experience where cars were worked by electricity or cable they were always larger than where cars were worked by horses, they would see there was considerable room for saving in the future working of the tramways. The committee would probably, in a short space of time, recommend the Council to adopt, at least on a portion of the lines, the working of the tramways by accumulator motors. The committee had had a meeting with the tramway company in regard to the acquiring of the stables. They had a long and very interesting meeting with the company, the result of which was that the company had now submitted an offer to sell the whole or portions of their plant and stabling. Which of these offers or any of them would be entertained was a matter for future consideration. They had remitted to a sub-committee to look carefully into this matter, and submit a recommendation whether they should buy the whole or only certain portions, either of which proposals the company seemed perfectly willing to entertain. Another matter of vast importance was one with which the Town Council probably had not hitherto been familiar—that was the report which had been submitted by their engineer (Mr. Rankine) regarding the condition of the lines at the termination of the lease. They knew that Mr. Rankine was an extremely fair man, and in the reports, with his usual fairness, he had not attempted to make the lines either better or worse than he had good reason to believe they would be two and a half years hence, at the termination of the lease. If the report was correct, the tramway company would have a very considerable sum of money to pay the Town Council at the termination of the lease. The committee had considered this matter very fully. They had taken the advice of their law agent in the matter, and they had no hesitation in recommending the Town Council to take their stand on the report which they had received from Mr. Rankine.

Mr. Tait seconded.

Questions were asked as to the exact position of parties at the expiration of the lease, and it was explained that the "lines" had to be handed over in as good a condition as when they were taken over. The minutes were then agreed to.

THE ELECTRIC LIGHT AT PORTSMOUTH.

According to the *Hampshire Telegraph*, in accordance with the instructions of the Electric Lighting Committee, Prof. William Garnett has submitted to the Portsmouth Town Council an estimate of capital and current expenditure and receipts for the lighting of the district specified in Schedule B of their provisional order, and of the esplanade between the two piers. The estimate is based upon the assumption that in accordance with the recommendations contained in his report of October 14th last, alternating currents at a pressure of 2,000 volts will be employed for the transmission of energy through the main leads, and that turbo-electric generators, with surface condensers, will be employed. The grammar school has been selected as the point from which the lines of high-tension mains should diverge, and it has been assumed that the distance of the central station from this point will not exceed 500 yards. Prof. Garnett states that if it is impossible to fulfil this condition, the extra cost of mains will be at the rate of £2,700 per mile for the distance between the central station and the grammar school. Concentric mains will be laid from the central station to the grammar school capable of carrying sufficient current for twice the number of lamps for which it is intended at present to provide. These conductors together will serve all the requirements of the station until lamps have been installed equivalent to about 17,000 lamps of 16 c.p. Concentric high-tension mains will be laid from the grammar school along the principal thoroughfares mentioned in Schedule B of the provisional order and Alexandra-road. Along the Commercial-road route as far the corner of Lake-road, and to Southsea as far as the corner of Osborne-road and Palmerston-road, high-tension mains will be laid capable of carrying about twice the current for which provision is at present to be made at the generating station. This will provide for the increased demand which will occur when the system of mains is extended to North End and the Beach Mansions. The cost of extending the lighting system in these directions, including high and low tension mains and transformers, will be at the rate of about £2,600 per mile. For the purpose of public lighting in the streets, instead of arc lamps, placed at distances of 50 yards or more, Prof. Garnett prefers to employ "high efficiency" incandescent lamps of 150 c.p., fixed at distances of about 30 yards. These lamps would be supplied directly from the low-tension conductors, and two of them would require about the same power as a single arc lamp. They would need to be more frequently renewed than ordinary incandescent lamps, and this has been taken into account in the estimate of annual expenditure. If incandescent lamps are adopted, only very light columns will be required for their support, and they will need no attention until they require renewal, while the present lamp columns may be used in most cases. Arc lamps require expensive standards, and cost about £4 each per annum for carbons and trimming, if burning until midnight only. As the conductors along the Clarence Esplanade will be used for public lighting only, so that all the lamps connected with them will be switched on and off together, and as no small lamps are required in this situation during the whole night, it will be convenient to switch the whole of the lights on and off simultaneously by means of a high-tension switch at the point at which the esplanade conductors branch from the mains near the Pier Hotel. On a public promenade the lighting up simultaneously of 90 powerful lights will be effective. For the lights along the Clarence Esplanade arc lamps are less unsuitable than in the streets, but high-power incandescent lamps would meet the requirements of the situation. Though the capital required for the installation of 8,800 private lamps and 200 public lamps is

estimated at little more than £28,000, the professor reminds the committee that it is desirable that borrowing powers should be obtained for a much larger sum, in order to enable extensions to be made to the system from time to time, as the public may demand, without renewed application to the Local Government Board. The cost of the site is an item not included in the capital estimate, and no allowance has been made for the renewal of lamps used for lighting the central station, inasmuch as the blackened lamps taken down from the street columns may be used in the engine-room until they are broken up. So long as the number of private lamps wired is less than the equivalent of 8,800 60-watt lamps, the income will be less than the amount estimated, and the expenses will also be less, but not in the same proportion. There appears, however, to be a reasonable margin to meet this difference, and if the public lighting is undertaken at once the installation may be expected to pay its working expenses and interest on capital actually invested as soon as the number of private lamps wired exceeds 5,000. Prof. Garnett's estimate of the capital required for high-speed generating plant and incandescent lamps for public lighting is £38,285. He places the annual receipts for private and public lighting at £10,800, and the expenditure, including interest on £40,000 at 3½ per cent., at £7,572.

In presenting the scheme summarised above, the Electric Lighting Committee reported at Tuesday's meeting of the Council that they had had reason to reconsider the scheme prepared by Mr. Shoolbred for an electric lighting installation in the borough and the recommendation based upon it, and they had obtained a further report on the subject from Prof. Garnett, which they now submitted for the consideration of the Council. The committee recommended that the resolution of the Council passed on September 8 last, so far as it referred to the adoption of Mr. Shoolbred's scheme, be rescinded, but that this should not apply to so much of such resolution as referred to the borrowing of £60,000. They further recommended that the scheme and report of Prof. Garnett be adopted, and that he be appointed as consulting engineer, and that Messrs. Waller and Manville be appointed as superintendent engineers; the fee for the consulting engineer and the superintendent engineers to be £1,500 together. With the view of carrying out the scheme embodied in Prof. Garnett's report, the committee recommended that they be authorised to acquire a sufficient site for the central station.

Alderman Ellis moved the adoption of the report and briefly related the circumstances under which the committee abandoned the plan submitted by Mr. Shoolbred for that now submitted to the Council for consideration. He stated that Mr. Shoolbred had estimated the annual income to be derived from the electric light and the expenditure at £8,939, leaving a fair margin for profit. Before a definite arrangement had been arrived at a doubt arose as to whether Mr. Shoolbred had not overestimated the revenue, and the committee invited him to meet them and prove that his figures were correct. He failed to satisfy them, and they had no alternative than to dispense with his services, it being clear that he had not taken into consideration the nature of the town he had been called upon to light. Prof. Garnett was called in for consultation, and he expressed an opinion that Mr. Shoolbred's estimate of £10,000 was £2,300 more than could be reasonably anticipated, it being unlikely that they could earn more than £1 for each lamp wired. Moreover, it would be impossible to extend the light beyond the area contained in the provisional order without ruinous cost.

Mr. Beale seconded the resolution.

Mr. Miller observed that Prof. Garnett had been called in to sit in judgment on his rival's scheme.

Alderman Ellis: I object to that.

Mr. Miller: You may object, but I shall say it. If I happened to be a professor I should do the same thing.

Mr. Beale: Right or wrong?

Mr. Miller: Yes; I should try to crab my rival. Continuing, Mr. Miller said that the matter was of considerable importance, for it involved the expenditure of £60,000. Only four months ago the Electric Lighting Committee assured the Council that in selecting Mr. Shoolbred's system they were perfectly right and perfectly safe, and he asked what justification had they now in making a similar representation with regard to Prof. Garnett's plan? He desired to know whether Prof. Garnett had had experience in the matter of electric lighting, and whether he could point to a town in which his system had been adopted in preference to others. Undoubtedly electricity would furnish the light of the future, but he thought that Portsmouth could afford to wait and see what other towns were doing. He moved as an amendment that the consideration of the report be deferred to an adjourned meeting of the Council a fortnight hence.

Mr. Pulljames seconded the amendment, and said that when Mr. Shoolbred's scheme was recommended for adoption he seconded Mr. Miller's amendment that the matter be deferred for three months. They stood alone then, but events had proved that they were not wrong. Possibly, if they adopted the new scheme hurriedly, they might be led astray by Prof. Garnett, as they had been somewhat led astray by Mr. Shoolbred.

Mr. Light asked what previous experience in the installation of the electric light was possessed by Prof. Garnett.

The **Mayor** said the two men engaged with Prof. Garnett were now effecting a public installation at Dublin.

Mr. Miller: Ah! the men engaged with him.

The **Mayor** said the committee had adopted Mr. Shoolbred's scheme on the strength of a report received from a deputation who visited Bradford. The deputation, of whom he was one, were delighted with what they saw of Mr. Shoolbred's scheme in operation there, but they overlooked the fact that Bradford was a compact town, with all its business houses in one centre, whereas Portsmouth was a scattered borough, for which the low-tension system was wholly unfitted.

Alderman Ellis asked that before the amendment was voted upon the Council would empower the committee to purchase a site for the central station. It was necessary that the site should be close to the sea, and in the neighbourhood that the committee had selected there was but one available site without a license upon it, and that site must be purchased before the day was out, or it would be sold the next morning.

The amendment was, however, put to the vote, when it was carried by 16 to 12.

READING ELECTRIC LIGHTING.

The following report has been submitted to the Council by the Highways Committee on the question of electric lighting:

The borough surveyor reported that it was suggested by the Reading Electric Lighting Company that 30 1,200-c.p. lamps be used. These lamps would take the place of 236 5ft. flat flame burners, the cost of which is as follows: Lamps lighted by Corporation, £323. 15s. 11d.; by Simeon's Trustees, £25; by Gas Company (at their own expense, £54. 10s. 6d.; or a total cost of £403. 6s. 5d. per annum for gas lighting, producing 3,776 c.p before 11 p.m. and 1,408 c.p. after 11 p.m.

The cost of lighting, cleaning, and maintaining 30 electric lamps (seven years' contract), each giving 1,200 c.p. throughout the time of lighting, or a total illuminating power of 36,000 c.p., would be £27. 15s. each, or £832. 10s. for 30.

The cost of lighting cleaning, and maintaining 30 electric lamps (seven years' contract), each giving 1,200 c.p. until 11 p.m., reduced to 16 c.p. after 11 p.m., or a total of 36,000 c.p. until 11 p.m., and 480 c.p. after 11 p.m., would be £22. 15s. each, or £682. 10s. for 30 lamps.

From the above figures it will be seen that if electric lamps at 1,200 c.p. all night be adopted, the total cost of lighting the streets shown would be about doubled, whilst the illumination of the streets would be nearly 10 times greater than at present.

If the scheme for 1,200-c.p. lamps, reduced 16-c.p. lamps at 11 p.m. be adopted, the illuminating power would be nearly 10 times greater than at present before 11 p.m., and about one-third of what it is at present after 11 p.m.

It must, however, be borne in mind that the electric lamps would be three times farther apart, on the average, than the gas lamps, and, as the intensity of the light diminishes much more rapidly than the distance from it increases, the average lighting of the streets would, with 1,200-c.p. lamps, be about five times greater than at present. The lighting at the mid-spaces between the lamps would be slightly greater than at present.

With the 16-c.p. lamps the lighting of the mid-spaces between the lamps would be much less than it is at present after 11 p.m.

I am of opinion that it would be much more economical to maintain the lamps at 1,200 c.p. all night than to reduce them to 16 c.p. at 11 p.m.

I think, however, that a saving might be effected in another way. The whole of the street lighting current for the 1,200-c.p. lamps would, in any case, be carried by a set of conductors used for no other purpose, and as the lamps will be illuminated or extinguished by the turning on or off of the current at the generating station, it appears to me that full advantage could be taken of all times of brilliant moonlight, thus saving electric current.

With regard to the quotations made by the electric light company, I find that for the St. Pancras electric lighting it has been estimated that the cost of lighting and maintaining a 1,200-c.p. lamp would be 2d. per lamp per hour, or a cost per annum for 3,900 hours of £32. 10s.

This estimate of cost is borne out by the experience of places in which electric lighting has been carried out in a thoroughly efficient manner.

A letter was read from the solicitor to the electric lighting company submitting an alternative scheme and an estimate for public lighting for the same area. The principal feature of the scheme is a combination of the arc and incandescent systems of lighting; each lamppost will support one arc and one incandescent light. Up till about 11 o'clock the arc lamps will be lighted, and at that hour the incandescent lamps will be lighted and the arc lamps shut off. This proposal appears to offer the advantages of a largely increased amount of lighting during the earlier hours of night, and during the remainder of the night nearly the same as the lamps at present in use afford. The following is the estimate for public lighting as an alternative scheme to the estimate already sent in to the Highways Committee:

Price per lamp per annum for 1,200-c.p. lamps burning up till 11 p.m., from 11 p.m. 16-c.p. lamps—3,900 hours' lighting per annum if contract is given now, so that the public lighting mains can be put in at the same time as the private mains:

	If Corporation find lampposts. £ s. d.		If company find lampposts. £ s. d.
30 lamps, seven years' contract...	22 14 0	...	24 0 0

COMPANIES' MEETINGS.

EASTERN TELEGRAPH COMPANY.

Report of the Directors for the half-year ended September 30, 1891, presented to the thirty-ninth half-yearly ordinary general meeting held at Winchester House on Thursday.

The Directors submit the accounts and balance-sheet for the six months ended September 30, 1891. The revenue for the period amounted to £354,939. 5s. 4d., from which are deducted £97,130. 15s. 1d. for the ordinary expenses, and £47,047. 18s. 1d. for expenditure relating to repairs and renewals of cables, etc., during the half-year. After providing £4,816. 5s. for income tax, there remains a balance of £205,944. 7s. 2d., to which is added £313. 15s. 9d. brought from the preceding half-year, making a total available balance of £206,258. 2s. 11d. From this balance there have been paid :

Interest on debentures and debenture stock	£28,274 12 10
Dividend on preference shares	20,474 3 0
Two interim dividends of 2s. 6d. per share each on ordinary shares	100,000 0 0
	£148,748 15 10

leaving a balance of £57,509. 7s. 1d., which is carried forward to the next account. The revenue includes £33,398. 18s. 5d., dividends for the half-year upon the Company's shares in the Eastern and South African, the Black Sea, the Direct Spanish, and the African Direct Telegraph Companies. The traffic over our whole system is satisfactory, and the revenue derived from Australian telegrams since the reduction of tariff is developing favourably. In accordance with the provisions of the articles of association, two of the directors, Sir A. J. Leppoc Cappel, K.C.I E., and Lord Sackville A. Cecil, retire by rotation at this meeting, and, being eligible, offer themselves for re-election. The auditors, Mr. Henry Dever, and Messrs. Welton, Jones, and Co., retire, and offer themselves for re-election.

Sir John Pender, K.C.M.G., chairman, presided at the meeting.

Before proceeding to the business before the meeting, the **Chairman** referred in sympathetic terms to the dark shadow which had fallen on the Royal Family through the death of the Duke of Clarence, and said that the news had been rapidly communicated to the vast Empire owned by this country through the medium of that Company's lines. Turning to the accounts, he said that their message receipts for the half-year ended September 31 last amounted to £321,135, as against £318,728 for the corresponding period of the previous year, an increase of £2,407. Dividends from their investments showed a decrease of £56. Interest and transfer fees had fallen off £285. The gross revenue was £354,939, as against £352,875, an increase of £2,066. The reduction of rates for European telegrams, which came into operation on July 1st last, he was glad to say had nearly been recouped, thus showing that there was considerable vitality in their business. Included in the accounts was the loss on five months' reduced tariffs to Australia. The reduction was still in force, and they had only had eight months' experience of it. At the end of the 12 months he thought they would be able to make a very satisfactory report on this head. They had already recouped some of the smaller losses by increased traffics in other directions than Australia. They were, on the whole, very well satisfied with the result of the conference which was held about 12 months ago. He was hopeful that a considerable portion of the loss on the Australian traffic up to the end of September, would be made up by increased receipts before the end of the financial year. The total expenditure for the half-year under review amounted to £97,130, as against £91,793, an increase of £5,407. Included in these figures was, however, the item for special repairs at Alexandria and Port Said. The amount carried to maintenance and ships' reserve fund was £4,000, as against £2,500. The working expenses showed an increase of £4,062. The amount paid for use of patents showed a decrease of £661, which was a permanent reduction, owing to some of the patents used by them having expired. Cable renewals and repairs showed an increase of £15,570. In 1890 this amount was exceptionally light, owing to their ships being hired by other companies. They had laid in 129 knots of new cable, the cost of which was included in the figures for the half-year. They carried forward £57,509, against £78,196, or a decrease of £20,666, but it must be remembered that the half-year ended September, 1890, was, as regarded ships' expenditure, an exceptionally favourable one. He would call their attention to the important fact that notwithstanding the large additions to their cable system during the last six years, the capital expenditure under this head had remained since 1885 at practically the same figure, in spite of the fact that they had laid over 7,000 miles of new cable during that period. This half-year they had applied from the reserve fund the sum of £105,110 in reduction of capital expenditure. About 11 years ago shareholders were good enough to sanction what was then called an insurance fund. A few months ago when he was addressing the Eastern Extension Telegraph Company, he drew the attention of the shareholders to an amended system which the Board were desirous of introducing, and which at the present time was in the hands of the actuaries. Probably youths were, as far as fingers were concerned, better for telegraphic work than older men. If they were to get good people, they must hold out to them some little benefit at the end of their arduous life. They thought to encourage thrift and economy on the part of their employés by meeting them and adding to the sum they might save, so that they might retire with a competency at the end of their service. Great confidence had to be placed in the men who worked their business, and they must be rather above the ordinary class, well-educated, well-connected men, who had some feeling of respect for their name and position. They had also to bear in mind that a great deal of their business was conducted in distant countries and tropical climates, and never in very pleasant places, because they had to have the bulk of their staff near to the place where the cables were landed. Consequently, their employés led an isolated life, and one which did not, he thought, tend very much to health. Therefore, they should be just and generous to these young fellows who embarked with them, and were in touch with them through the course of their working life. These remarks having been received with evident approval, the Chairman said he was glad they approved of the scheme, of which he could not give them the details, as these were being worked out most carefully. Their business was thriving. It was carrying out what he always told them, that every day that they lived telegraphy became a greater necessity. The world could not move without it, and as the world grew so must telegraphy. That Company was at the head of it. They still had some cables to duplicate, and some money yet to expend, but they took care before they spent the money to see where it would come from. Above all things, they were most desirous not to overburden themselves with capital. When they took into consideration the reduced value of money, and the fact that they still maintained their high rate of dividend, he thought the shareholders would be satisfied that their investment was good and sound. It was believed to be so by the whole commercial community of this and other countries. Taking the last two years and looking at the convulsions which had shaken the proudest houses to their foundations, when they saw the great depression that had followed in commerce, and when they saw the stock of the Eastern and Eastern Extension Companies standing higher than at any period of their existence, he could not offer better evidence of belief in their property. Moreover, when they found that their 4 per cent. debentures were at the present moment at 108 to 109—that was further evidence, that as debentures and as an investment their property ranked probably in the first class of investments. He moved the adoption of the report and accounts.

The **Marquis of Tweeddale** seconded.

Several shareholders spoke with pleasure of the scheme for an employés' superannuation fund, and hoped the older men would not be forgotten. In reply to questions,

The **Chairman** said that they were not forgetting the old men. As to all their cables being in working order, they were above the average in this respect. The Company was rarely without a broken cable, but owing to their system being duplicated, the public knew very little about such matters. A very important break had taken place in the South African cable the other day, and had they not had their ships in order to attend to it at once the work might have taken two months—as it was, the cable was repaired in five days. They repaired their own cables, and some of other people's too. They never allowed their ships to lie idle if they could help it, and they never lost an opportunity of making them earn the nimble penny. Last half-year (1890) they earned outside of their own companies, by means of their ships, £22,000, and the year before, £15,000.

The resolution was then put, and carried unanimously ; as also were motions re-electing Sir A. J. Leppoc Cappel and Lord Sackville A. Cecil, directors, and Messrs. Henry Dever, and Welton, Jones, and Co., auditors.

A vote of thanks to the Chairman closed the proceedings.

COMPANIES' REPORTS.

DIRECT UNITED STATES CABLE COMPANY.

The report of the Company for the six months ended Dec. 31 shows that the half-year's revenue, after deducting out payments, amounted to £45,402, against £43,346. The working and other expenses for the same period, including income tax, but exclusive of cost of repairs of cable, amounted to £17,672, leaving a balance of £27,729 as the net profit, making, with £3,502 brought forward, a total of £31,231. For the corresponding period of 1890 the working expenses and other payments amounted to £17,555. Interim dividends of 3s. 6d. per share for the quarter ended September 30, 1891 (paid October 24, 1891), and of 3s. 6d. per share for the quarter ended December 31, 1891 (payable Jan. 23, 1892), together amounting to £21,248, have been declared, and after setting aside £5,000 to the reserve fund account, the balance of £4,982 on the revenue account has been carried forward.

NEW COMPANIES REGISTERED.

Electric Fittings, Hiring, and Maintenance Company, Limited.—Registered by Messrs. Ashurst, Morris, Crisp, and Co., 17, Throgmorton-avenue, E.C., with a capital of £200,500, divided into 40,000 ordinary shares and 500 founders' shares of £5 and £1 respectively. The holders of the founders shares may, at any time after such shares are fully paid,

by a resolution passed at a meeting of such holders, determine that each founders' share shall be subdivided into founders' shares of such smaller amount as the meeting may determine, and thereupon the founders' shares shall be subdivided accordingly. As to the sum set apart out of the net profits of the company as a reserve fund, one-half thereof shall belong to the holders of the founders' shares, the other half to the holders of the ordinary shares, and the balance of the net profits shall be divided into two equal parts, one of which shall belong to the holders of the founders' shares, and the other half to the holders of the ordinary shares, and shall be divided among them in proportion to the amounts paid upon the ordinary and founders' shares respectively. The objects of the Company are to establish and maintain cables, wires, lines, accumulators, lamps, works, and fittings of every description for the generation, distribution, supply, accumulation, and employment of electricity; and to carry on business as electricians, generators and suppliers of electricity, mechanical engineers, manufacturers of and dealers in all kinds of apparatus therefor, as iron, brass, and other metal founders and fitters and metal workers; to effect insurances against fire or accidents arising from the employment of electricity. The first subscribers are:

	Shares.
A. Armstrong, The Albany, Piccadilly, W.	1
B. H. Martindale, Bickley, Kent	1
W. Crookes, F.R.S., 7, Kensington Park-gardens, W.	1
F. R. Reeves, Settle-heath, Potter's Bar	1
A. Palliser, jun., 21, Lime-street	1
H. Fleet, 4, Hayworth-road, Clapton	1
J. W. Fricker, 14, Addison-grove, Croydon	1

There shall not be less than three nor more than seven Directors; the first are to be nominated by the signatories to the memorandum of association. Qualification: £200. Remuneration: Chairman, £400; deputy-chairman, £300; and ordinary directors, £200 per annum each. An additional sum, equal to 5 per cent. on the net profits of the Company after payment of 7 per cent. dividend, shall be divided amongst them as they shall determine.

BUSINESS NOTES.

Dividend.—The Globe Telegraph and Trust Company announce interim dividends of 3s. per preference share and 1s. 6d. per ordinary share.

Cable Repaired.—The Eastern Extension Telegraph Company announce that their Hong Kong-Bolinao cable is now repaired, and telegrams can therefore be accepted for transmission to Manilla as usual.

City and South London Railway.—The receipts for the week ending 10th inst. were £858, against £748 for the corresponding period of last year, showing an increase of £110, and a decrease of £20 as compared with the week ending Jan. 3.

PROVISIONAL PATENTS, 1892.

JANUARY 4.

106. **Improvements in electric switches.** Wilson Henry Sturge, 12, Cherry-street, Birmingham. (Complete specification.)

109. **Improvements in telephone exchange systems.** Abner Mulholland Rosebrugh, 107, Mutual-street, Toronto, Canada.

110. **Improvements in generating and distributing electrical energy.** Rankin Kennedy, Carntyne Electric Works, Shettleston, Glasgow.

111. **Improvements in distributing and converting alternating electric currents, and in apparatus therefor.** Rankin Kennedy, Carntyne Electric Works, Shettleston, Glasgow.

152. **Improvements in vulcanising the insulating covering of electric conductors.** George Gatton Melhuish Harding-ham, 191, Fleet-street, London. (John Joseph Charles Smith, United States.)

JANUARY 5.

177. **Improvements in electric drop light.** Gwynne Ernest Painter, 11, Wellington-street, Strand, London. (Complete specification.)

207. **An electric regulator.** Edwin John Houghton and William White, 28, Southampton-buildings, London.

JANUARY 6.

253. **Improvements in magnetic apparatus.** Walter Thomas Goolden and Sydney Evershed, Woodfield Works, Harrow-road, London.

259. **A method of utilising electrical energy for the heating of water and other liquids.** Arnold Beaumont Woakes, 78, Harley-street, London.

278. **A wall contact and plug for electrical conductors.** William White and Edwin Percival Allam, 28, Southampton-buildings, London. (Complete specification.)

310. **Improvements in or relating to joints and attachments for concentric armoured electric conductors, and the methods of making the same.** Joseph Devonport Finney Andrews, 41, Parliament-street, Westminster, London.

JANUARY 7.

334. **Improved form of a dry galvanic element.** Henry Nehmer, 4, Grafton-street, Gower-street, London.

355. **Improvements in or relating to the electro-deposition of tin upon metals.** Edwin Charles Furby, 19, Southampton-buildings, London.

359. **An improvement in dynamo-electric machines.** Siemens Bros. and Co., Limited, John Nebel, and William Abraham Collings, 28, Southampton-buildings, London.

360. **Appliance for equalising the loads of the several conductors of rotary-phase current installations.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, London. (Messrs. Siemens and Halske, Germany.)

372. **Improvements in soldering, melting, and coating metals by the aid of electricity.** Nicholas Benardos, 24, Southampton-buildings, London.

JANUARY 8.

406. **Improvements connected with electric motors and electric elevator apparatus.** The American Elevator Company (Incorporated), 55, Chancery-lane, London. (Otis Bros. and Co., United States.) (Complete specification.)

407. **Improvements in liquid electrodes.** Edmond Savary d'Odiardi, 55, Cornwall-gardens, London.

408. **Improvements in electro-inhalers.** Edmond Savary d'Odiardi, 55, Cornwall-gardens, London.

409. **Improvements in the electric static sprays.** Edmond Savary d'Odiardi, 55, Cornwall-gardens, London.

410. **Improvements in pneumo-dynamometers.** Edmond Savary d'Odiardi, 55, Cornwall-gardens, London.

411. **Magneto-voltaic electrode.** Edmond Savary d'Odiardi, 55, Cornwall-gardens, London.

JANUARY 9.

475. **Improvements in apparatus for testing insulation electric meters and alternating-current motors.** James Swinburne, Broom Hall Works, Teddington, Middlesex.

486. **Improved variable resistances for electrical purposes.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

487. **Improvements in means or apparatus for producing decorative, advertising, or other effects by the aid of electricity.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

491. **Improvements in and relating to underground conduits for electric wires.** Carl Axel Wilhelm Hultman, 18, Buckingham-street, Strand, London.

495. **An improved electric battery electrolyte.** George Henry Robertson, 47, Lincoln's-inn-fields, London.

499. **A new or improved dynamotor or continuous-current transformer, and method of winding the field magnets of such.** Francis Murray Newton and Tom Hawkins, Norfolk House, Norfolk-street, London.

NOTES.

Leith Docks.—A committee are considering the proposal to introduce electric light at Leith Docks.

Hawick.—Messrs. Mavor and Coulson are lighting a portion of the town of Hawick on contract as an experiment.

Fareham.—The Fareham Local Board have decided not to oppose the local company's application for a provisional order.

Leeds Electric Tramway.—Over 100,000 persons have been carried on the Roundhay Park-road since the opening.

Dessau.—At the Dessau central station a 120-h.p. Otto gas engine driving a Fritsche dynamo is used, running at 150 revolutions a minute.

Woolwich.—The undertakers under the Woolwich electric lighting order have applied for six months extension of time for depositing the £1,000 required.

Newspaper Lighting.—The *Daily Chronicle* have now their offices lighted by electric light. The installation was carried out by Messrs. Paterson and Cooper.

Average Hours of Lighting.—At Darmstadt the average duration of lighting for an incandescent lamp is 300 hours, at Elberfeld 700 hours, at Berlin 1,000 hours a year.

Electrical Portraits.—A speaking likeness of Dr. Silvanus P. Thompson appears in the *Electrical World*, N.Y., for Jan. 9, with a very appreciatory account of his scientific work.

Yorkshire College.—The first of a series of free lectures in the People's Hall connected with the Yorkshire College, Leeds, has been given by Prof. Stroud, D.Sc., on "The Telephone."

Electric-Coloured Boy.—During a thunderstorm in Maine, says a recent paragraph, the skin of a boy who was struck by lightning turned to a dark purple, and has remained so ever since!

Vetoing the Trolley.—The Mayor of Brooklyn, U.S., has vetoed the proposed scheme for the introduction of the trolley into that fashionable suburb of New York. It is hoped to get his veto upset.

Personal.—The Queen has been pleased to approve the appointment of Lord Rayleigh to be Lord-Lieutenant and Custos Rotulorum of the county of Essex, in the room of Lord Carlingford, resigned.

Electric Railways in France.—The contract for establishment of an electric railway between Veyrier and Monnetier-Mornex (Haute Savoy) has been entrusted to MM. de Meuron et Cuénod.

Utilising Niagara.—It is expected that the first contract to be entered into by the company which is to utilise the water power of Niagara, will be for the delivery of power to light the city of Buffalo.

Electric Tanning.—We have received a pamphlet with opinions of various authorities on the Worms et Balé process of electric tanning, published by M. A. Zwierzchowski, 32, rue Etienne-Marcel, Paris.

Institution.—The inaugural address by Prof. Ayrton, F.R.S., president of the Institution of Electrical Engineers, has, by reason of the lamented death of the Duke of Clarence, been postponed till the 28th inst.

Yarmouth.—Upon the statement by Mr. J. Harry Palmer at the Yarmouth Town Council, that electric light would cost twice as much as gas for the public lighting, the question was referred back to the committee.

Hammersmith.—The Hammersmith Vestry, after two hours' debate, have given their consent to the provisional order for the electric lighting of the district by the Putney and Hammersmith Electric Lighting Company.

City and South London.—We understand that a meeting of the shareholders of the South London Electric Railway will be held shortly to consider the question of the immediate extension of the railway to Islington.

Cleckheaton Town Hall.—The formal opening of Cleckheaton Town Hall will take place on February 10th, and the electric light, obtained from a 14-h.p. gas engine, has been installed, and will be used on the occasion.

Battersea.—A special committee of the Battersea Vestry is considering the question of electric lighting, and the Board of Trade has been asked to defer decision on applications for provisional orders until the matter has been dealt with by the Vestry.

Mutual Telephones.—We have received the January list of subscribers to the Mutual Telephone Company, of Manchester, which indicates the continued energy and increasing prosperity of the company. The list already contains about 900 names.

Royal Society.—At the Royal Society on Thursday papers were read by Major Cardew, "On a Differential Electrostatic Method of Measuring High Electrical Resistances"; Prof. Schuster, F.R.S., and A. W. Crossley, "On the Electrolysis of Silver Nitrate in Vacuo."

Moffat (N.B.)—The Moffat Municipal Authority had the question of lighting the town by electricity before them at their last meeting. The clerk was directed to enquire upon what terms Mr. J. J. Hope-Johnstone, of Annandale, will grant the dyemill water power for that purpose.

Whitehall Club.—A dinner of the electrical engineers who are members of the Whitehall Club is to be held on Friday, the 29th inst., at the club. It is hoped that Mr. Tesla will be present, unless the postponement of his lecture from the 28th inst. to February 3 delays his arrival in London.

Dewsbury.—At the meeting of the Dewsbury Town Council held on Friday, the Gas Committee reported that they had sent out circulars to 221 persons and firms, enquiring if they would take the electric light in case the Corporation laid down a public installation, and only nine had given assent.

Jarrow.—At the monthly meeting of the Jarrow Town Council on the 13th inst., it was recommended that the town clerk be instructed to communicate with three or four of the principal electric lighting companies in the district inviting them to apply for permission to supply the borough with the electric light.

Proposed Electric Railway in Paris.—The Prefect of the Seine, says Dalziel, has received a proposal from a firm in London for a concession to construct an underground electric railway in Paris on an entirely new system. The subway would extend over 25 kilometres, and have five branches, connecting all the chief points of the capital.

London Electric Railways.—Among the private Bills which passed the examiners last week was one for the extension of the City and South London Electric Railway to Islington. In respect to the proposed Waterloo and Royal Exchange Railway there was no appearance on behalf of the promoters, and the Bill was struck out of the list.

Taunton.—At the monthly meeting of the Taunton Town Council on the 13th inst., the proposed acquirement of the properties of the gas and electric light companies was discussed at some length, and ultimately the matter was referred to the Streets and Highways Committee and the Finance Committee, who will be merged for the consideration of the subject.

Nottingham.—The celebrated Castle Museum at Nottingham is to be lighted by electric light. Mr. G. H. Wallis, the curator, will show the rooms. Persons desirous of tendering may send in sealed tenders and specifications, to be opened at the next meeting of the Castle Museum Committee. Further particulars of the curator, or of Mr. Samuel G. Johnson, town clerk.

Lynton and Lynmouth.—The electric light is rapidly becoming appreciated in Lynton and Lynmouth. Mr. H. H. Benn, the proprietor of the works, has just installed the light in the Devon and Cornwall Bank, as well as the manager's residence—the first private house in the neighbourhood in which the electric light has been adopted, and the result is found very satisfactory.

St. Helens.—A Local Government Board enquiry has been conducted here by General Phipps Carey, partly relative to the electric lighting of the Town Hall, which is greatly desired. The town clerk explained that there will be 335 16-c.p. lamps throughout the building, the engines and dynamos being regarded as a temporary arrangement until the whole town has the electric light.

Liverpool.—The Watch Committee of the Liverpool Corporation on Monday considered a memorial from 448 commercial firms in the city using the electric light, praying the Corporation to consent to the application of the Liverpool Electric Supply Company to extend the term of purchase in the city to 42 years. The committee decided that they could not grant the application in its present form.

Lauffen-Frankfort Plant.—Recent statistics of the figures obtained with the Frankfort transmission plant show that the commercial efficiency was over 72 per cent. The cost per effective horse-power was about £56. 10s., the distance of transmission being, as will be remembered, 110 miles. It was half expected that there might be extraordinary losses not deducible from Ohm's law, but the results show that this was not the case.

Shoreditch.—A communication from the Gas Light and Coke Company was read at the last meeting of the Shoreditch Guardian Board, stating that the price of gas would be raised to 3s. 1d. per 1,000ft., an increase of 4d. per 1,000ft. It was suggested that Mr. Joyce, the engineer, should be consulted as to the employment of electric light. The question was referred to committee in order that they might consult with the engineer.

Waterford.—Tenders are required for the public lighting of part of the city at present lighted by electricity, and also in the alternative for the public lighting of the entire city, either by gas or electricity, for periods of two, five, or ten years, from September 1, for the Public Lighting Committee. Tenders to be sent to Mr. Joseph W. Howard, town clerk, by February 1. All information can be obtained at the office of Mr. M. J. Fleming, borough surveyor, The Mall, Waterford.

Tesla's Experiments.—During the past six months Mr. Tesla has been hard at work developing the experiments he gave before the American Institute of Electrical Engineers, in the direction of important practical applications. Some of the points of his work are already embodied in patents on incandescent lighting and on condensers. Many of the practical difficulties have already been overcome, and it is hoped that ere long the results may be seen in commercial use.

"Evil (Telephonic) Communications Corrupt."—At Dundee the National Telephone Company sued John Milne and Son for £8. 10s., rental of telephone. Mr. Urquhart, for his clients, stated that inefficient service was given at the time of the day most required, and urged that half the profanity amonst the Cowgate merchants was due to the bad telephone service. It was by no means improving to their morals. The case is being continued.

The Old Students' Association.—In accordance with the announcement made at the last annual dinner Mr. Reginald J. Jones has been obliged, owing to pressure of professional work, to resign the hon. secretaryship of the Old Students' Association. Mr. E. B. Vignoles has been appointed as hon. secretary and hon. treasurer, and Mr. A. E. Ruddock as assistant hon. secretary. All correspondence and subscriptions should therefore in future be sent to Mr. E. B. Vignoles, 28, Lanhill-road, Elgin-avenue, W.

Electric Leakage through Snow Contact.—Snow has fallen so heavily in the districts of Gex, Nantua, and Bugey, says Dalziel's correspondent at Lyons, that telegraphic communication has been suspended. Curious phenomena have occurred at Culos, where electric light wires have been so heavily covered with snow that a kind of partial contact has been established, and a series of lightning flashes between the different wires has been going on for some time, to the great delight of admiring crowds.

Cantor Lectures.—Before the Society of Arts, on Monday next, January 25, Prof. Forbes, F.R.S., will deliver the first of his series of the Cantor lectures on "Developments of Electrical Distribution." Lecture I. will deal with low-pressure supply; comparison between 1885 and 1892; central station *v.* isolated plants; electricity *v.* gas; cost of feeders and mains; management of feeders; use of recording apparatus; house wiring; three and five-wire systems; use of motor-dynamos as compensators; and use of batteries.

Contraction of Copper Mains.—A new cause of interference of the electric light supply has been found in the action of frost. A drop of some 20deg. took place a little while ago, it will be remembered, and at Bath the light failed at this time, due, Mr. Massingham states, to contraction and expansion in the joints of the main. The Electric Light Committee of the Bath Town Council is to make an exhaustive report upon the subject. It would be interesting to hear if any other companies have experienced difficulties from the same cause.

Electric Canal Boats.—Electric motors for canal boat propulsion has been often proposed with many variants in design. A likely scheme is that described in the N. Y. *Electrical Engineer*, as proposed by Mr. Otto Büsser. A stationary cable is laid along the bottom of the canal. This cable passes over sheaves in the canal boat, driven by a motor, the current for which is supplied by trolley wires in the usual way. A peculiar feature is that the installation is transportable, being fitted on the gunwales of the boat as it enters the canal, and removed at the further end.

Glasgow Tramways.—At last week's Glasgow Town Council meeting, Bailie Paton intimated that the Tramway Committee had found that the offer of the General Electric Traction Company would enable the Corporation to work the tramways at 1d. per mile less than it could be done by animal power. This would be a saving of £18,000 a year. It was proposed at the end of the lease, two and a half years hence, to begin to use electricity for some por-

tions of the line. The committee were negotiating with the tramway company for the whole or part of the stabling and plant.

Factory Lighting.—The New York Mills, in Nidderdale, which about three years ago were purchased by Messrs. Thomas Gill and Sons, twine manufacturers, and have since been rebuilt, are now lighted by the electric light, the dynamo being worked by a turbine placed specially for the purpose, so that the mill machinery and the electric light may be worked independently of each other. The installation has been carried out by the Roper Engineering Company, of Bradford. This is the first instance of the electric light being brought into practical use in the district.

Fire Alarms at Chiswick.—The Chiswick Local Board met last week to consider and, if thought expedient, to accept tenders for the erection and maintenance of fire alarm posts, calls, etc. Tenders were opened as follows: Roxburgh and Co., with telphones £330, without £290; Messrs. Blenheim and Co., with, £379; Messrs. Spagnoletti and Crookes, with £415, without £365; Mr. F. E. Stuart, with £438. 17s., without £368. 17s.; and the Home Telephone Company, with £300, without £265. The Board decided that Dr. Diplock, as captain of the fire brigade, should consult with the surveyor on the tenders and report to the Board.

St. Pancras.—The arc lights at St. Pancras have been turned on in Tottenham Court-road to the satisfaction of the inhabitants and the members of the St. Pancras Vestry. The turning on took place on Friday, and on Saturday in the small hours, the Electricity Committee, attended by Prof. Robinson and Mr. Eccleston Gibb, made some experiments as to the comparative intensity of lighting of the electric light and the gas. The 12 Brockie-Pell arc lamps were found to give considerably more light than the 85 gas lamps, besides rendering unnecessary some of the gas lamps down the side streets. Euston-road, from Trinity Church to Euston-square, has been similarly lighted since Tuesday.

Chester.—At the monthly meeting of the Chester Town Council, on the 13th inst., Alderman William Johnson moved, and Mr. J. J. Cunnah seconded, the adoption of a recommendation of the Watch Committee that a sum not exceeding £20,000 be voted for providing a first installation of the electric light for Chester. Alderman H. T. Brown opposed the motion, on the ground that if the matter were taken up by the Corporation all the risk and loss would fall upon the citizens, and they should be taxing the whole town for the purpose of making up the deficiency in the working expenses for the benefit of a few individuals. This was evidently not the feeling of the Council, as after considerable discussion the motion was carried by a large majority.

Mining Engineers.—It is proposed to establish a London Institute of Mining Engineers, having for its objects the advancement and encouragement of the sciences of mining, metallurgy, engineering, and their allied industries, the interchange of opinions by the reading of communications from members and others, and by discussions at general meetings, upon improvements in mining, metallurgy, engineering, and their allied industries, and the publication of original communications, discussions, and other papers connected with the objects of the institution. It is suggested that the institute should be lodged in suitable offices, which might also be jointly occupied by the Federated Institution of Mining Engineers. A spacious hall for meetings and for the formation of a mining library is also contemplated.

Medical Electricity.—The Institute of Medical Electricity has done useful work in introducing scientific electricity to the medical profession, and the earnest work of Mr. H. Newman Lawrence and Dr. Harries will certainly not be lost. But we suppose the institution did not pay as well as was expected, for it has lately been wound up voluntarily. Mr. H. Newman Lawrence is carrying on the same work upon his own account, and has opened rooms at 36, St. Martin's-lane, where he is intending to continue to treat patients by electricity and massage. Mr. Lawrence has our best wishes, as although the subject is difficult ground, his long work in attempting to apply electricity scientifically to the relief of paralysis, the "cataphoric medication," or dosing by electro-deposition of drugs, and other matters, have helped to pave the way to better use of electricity in medicine.

Edison Electric Railway.—The announcement of a novel and practical system of electric railway without overhead trolley wires by Mr. Edison some time back stopped, it appears, very many contracts for the trolley system being completed, the street railway companies in many instances preferring to wait until the value of the Edison system was demonstrated. Mr. Edison has issued a proclamation which will at any rate allay the fears of some of the other street railway engineers. He has authorised the statement that the new system is designed exclusively for roads of heavy traffic, in large cities, where the expense of a fresh line is warranted by the traffic, and where the overhead trolley is not admitted. "The new system," the statement continues, "will not be applicable, in a commercial sense, to long roads running less than 50 cars simultaneously. It must, therefore, be understood that outside of the large cities the best system that can be advocated is the trolley."

Inverness.—A committee meeting of Police Commissioners was held on Monday to consider the question of introducing electricity or extending the gas works by an expenditure of £10,000. The gas manager recommended that his scheme be modified to the extent of £2,300, but the convener of the Lighting Committee moved that the original scheme be adhered to in view of the improbability of the electric light being introduced. A motion in favour of delay to allow further discussion of the electric light scheme was moved by Mr. James Cook. Mr. Wm. Smith read a letter from a firm of London electric lighting engineers to the effect that the idea of generating the light at the Falls of Foyers was out of the question for a town of the size of Inverness, as it would lead to an expense of about £50,000; and Mr. Smith argued that this was the only scheme which could be entertained, as the taking of water from the Caledonian Canal would lessen the volume of the River Ness, and lead to litigation with fishing proprietors. After discussion, it was finally agreed to proceed at once with the extension of the gas works, provided the Police Commissioners are agreeable.

National Telephones.—A meeting of the Executive Council of the County Councils Association was held on the 13th inst. at the Guildhall, Westminster, Lord Thring in the chair. Among those present were Lord Baring, Baron Dimsdale, M.P., Sir John Dorington, M.P., Mr. Littler, Q.C., C.B., and representatives from Bedfordshire, Lancashire, Middlesex, Hertfordshire, Hampshire, Essex, Surrey, Monmouthshire, Lincolnshire, Northamptonshire, Gloucestershire, and Westmoreland. The Executive Council considered the private Bill which has been deposited in the Private Bill Office of the House of Commons for the purpose of affording "to the National Telephone Company, Limited, additional facilities for conducting the business of telephonic communication," and

resolved "That the attention of the Local Government Board and of the Board of Trade be called to the highly objectionable provisions contained in the National Telephone Company's Bill, and that it be suggested that the subjects contained in it ought to be provided for in a Bill introduced by a Government Department." It was arranged that the annual meeting should be held on the 17th of next month at the Guildhall, Westminster.

An Electrical Fog Bell.—The port of Ravenna in the Adriatic has recently, says the *Times*, been provided with a fog bell, the invention of the Abbé Ravaglia, worked by electricity. It is situated at the end of the mole leading into the harbour, and the current is conveyed to it from a battery in the lighthouse about a kilometre distant. The apparatus for striking the bell consists of a magneto-electric motor planted in the bell tower, and connected to a mechanical puller. When the current from the battery passes through the armature of the motor, the motion of the armature is caused to turn a disc having pins projecting from its border. These pins catch on the end of a pivoted lever as the disc revolves, and by raising one end of the lever depress the other, thereby pulling the bell chain and making the hammer strike the outer rim of the bell. A rapid series of strokes is the result, and the loud continuous note is heard for a long way. The battery employed is the constant form of Daniell, and a galvanometer is kept in the circuit to show that the current is of proper strength. A telephone circuit also enables the attendant at the lighthouse to hear the "drone" of the motor and thus know whether it is working at its proper speed. Such an apparatus is, under certain circumstances, cheaper, simpler, and more convenient than a steam syren or a bell actuated by the waves.

Pontypridd.—A deputation from the Pontypridd Chamber of Trade waited upon the Pontypridd Local Board last week for the purpose of bringing before the notice of the Board the lighting of the town, and urging upon them either to purchase the present gas works or to undertake the lighting of the town by electricity or some other illuminant. The deputation was introduced by Mr. H. S. Davies (president of the Chamber of Trade), who stated that in view of the ineffective lighting it would be desirable to take over the lighting themselves. Mr. Leyshon, chairman of the Board, said he was glad the deputation had waited upon them, as this would strengthen their hands. It was understood that the gas company intended to spend £2,000 on extensions. Councillor Roberts thought that partial lighting by gas and partial lighting by electricity would lead to difficulties. He agreed with the purchase of the gas works. Mr. Snape said the capital of the present company was not sufficient to meet the requirements of the district by properly enlarging the works. It was ultimately decided that the gas company should be written to and asked if they were prepared to treat with the Board for the sale of the works, and it was further decided to engage an expert to value the gas works. Perhaps, with further information before them, the Board would not be opposed to the introduction of electric light as well as gas. At any rate the present would seem a favourable opportunity for bring forward the subject.

Sunderland.—A special meeting of the Highways Committee of the Sunderland Corporation has been held to consider offers for lighting with electricity that part of the town comprised in the provisional order which was obtained by the Corporation in 1891. Applications had been invited by the Corporation from companies prepared to take over the powers, and two were received—viz., from the Brush Electric Supply Company and Messrs. Andrews and Co., London. The former proposed to take over the order with all its obligations on condition that the Corporation assisted them to form a local company, with arrangement for repurchase; that the public lighting should be given at such price as should be arranged hereafter; and that no concession of any kind be granted to any other company. Messrs. Andrews proposed to take over the area mentioned in the provisional order, to supply it with electricity for lighting purposes on the alternating-current high-pressure system at a uniform charge of 3¾d. per Board of Trade unit, and to pay the Corporation a rental of £100, together with a royalty according to the consumption. They required payment for the goodwill if at the end of 21 years the Corporation wished to acquire the concern. The terms of both offers were discussed, and it was ultimately agreed to submit the same to Mr. Shoolbred, who had previously been consulted by the committee with regard to the provisional order, and to await his report.

Walsall.—At the monthly meeting of the Walsall Town Council on Monday, a resolution was proposed by the Mayor, "That the Council carry out themselves their electric lighting order of 1890, and that they proceed to provide an electric lighting plant on the lines suggested in the report of Mr. Frederick Brown, A.I.E.E., at an estimated cost of £21,450, and that the Electric Lighting Sub-Committee be authorised to prepare and present for consideration plans and specifications of the proposed work, and a detailed estimate of the cost of the same." He said that they had to establish the light in the town, and the only question was whether it would pay. Mr. Brown held that with 2,000 lights of 16 c.p. each they would realise £1,266 a year profit on the expenditure of £21,000. He felt sure that this would be a step in the right direction, and that it was wise to keep the matter in their own hands. Birmingham certainly had not done their own electric lighting; but Birmingham did not always set a perfect example. Alderman Evans seconded. The Mayor stated that the streets at present proposed to supply were Digbeth, and Park, Bradford, Bridge, High, Darwall, Lester, and Goodall streets. Councillor Dean asked whether they would not at once include the centre of Bloxwich? Councillor Bowen suggested the centre of the Pleck as well, while the Mayor said that they thought it would be wise to deal with the centre of Walsall first. Alderman Lindop, in reply to Councillor Powell, said that the plant might be completed in about eight months.

City Lighting.—The directors of the City of London Electric Lighting Company, in announcing the issue of 9,848 ordinary shares at 5s. premium, give some information as to the progress of the City lighting. The two generating stations at Meredith's Wharf, Bankside, and at Wool Quay, Lower Thames-street, are both working. The supply of current has been commenced from each, and the erection of additional generating plant is being actively proceeded with. Queen Victoria-street, Gracechurch-street, King William-street, and Cornhill are already lighted, and the work is so far advanced that the lighting in many other of the main thoroughfares of the City will be commenced in a few weeks. In consequence of the exceptional facilities granted by the Commissioners of Sewers since their meeting of December 1 last, the opening up of the main thoroughfares has proceeded very rapidly, and the present rate of progress is about a mile a week. This will enable the company to reach the best paying districts of the City at an early date, and the earning of a substantial revenue will consequently be materially hastened. With reference to private lighting, they state that since the lighting of the Mansion House from the company's mains in December last the engineering staff has

been continuously employed in connecting the premises of further customers. Signed applications for about 13,000 lamps have been already received, and are being added to at the rate of 1,500 a week. Informal applications for a large additional number have also been made. With reference to revenue, an encouraging statement is made. For obvious reasons, they say, it is necessary when establishing an electric supply station to provide a staff out of proportion to the amount of current at first delivered. In spite of this drawback, however, Mr. David Cook, the company's recently-appointed manager, reports the revenue already being earned to be in excess of the current expenditure at the generating stations.

Accrington.—The Corporation of Accrington having obtained their provisional order for the supply of electric light, a scheme for the erection of a central station, with the laying of mains in the principal business thoroughfares, is now under consideration. The Council have issued a circular meanwhile to the inhabitants, in which they say: "Before establishing the central generating station, the Corporation is anxious to carefully ascertain what demand for the supply of electricity can be depended upon in the district in which the first mains are proposed to be laid, and as your premises are within that district will you please inform the Corporation whether you propose making use of the light and to what extent. The Corporation being desirous of affording information as to the probable cost of using the light, has consulted Mr. J. N. Shoolbred as to the price of the electric light in Accrington, as compared to the present price of gas. The price of the electricity to be supplied by the Corporation is limited by the provisional order not to exceed 8d. per unit. The illuminating value of a unit of electrical energy is about equal to that of 100 cubic feet of gas, so 10 units, with incandescent lamps of 16 c.p. each, will produce an amount of illumination about equal to 1,000 cubic feet of gas supplied by the company. This electrical energy, if supplied at 6d. per unit, is equivalent to gas at 5s. per thousand cubic feet. The cost of supply will, of course, vary with the demand—the greater the demand the less the Corporation will be able to supply the light at. To add to the cost of the light will be the meter rent at 10 per cent., as with gas meters, unless the consumer supplies his own meter. The consumer will, of course, provide his own internal fittings and lamps, and as regards these he is advised to make his own enquiries, the cost of same varying very much in the character of the fittings, the position and number of lights, and the internal arrangement of the premises to be lighted. It may, however, be stated that in the case of new buildings the internal fittings for the light have been found to cost about one-half that of gasfittings."

Unit Pole.—Mr. Chas. E. Emery made some sensible remarks with reference to unit pole and lines of force in the discussion on the recent paper on "Magnetic Reluctance," by Mr. A. E. Kennelly. "In investigating the formulæ for the construction of motors and dynamos," says Mr. Emery, "it becomes quite evident that 4π is nothing more or less than a simple arithmetical coefficient which, in this connection, has nothing to do with its customary significance as expressing the surface of a sphere of unit radius. It is thought that this should be emphasised by writing the figures instead of the symbol, or, for convenience of calculation, substituting a single special character, for instance *a*, for it, and stating its numerical value. The artificial conception that a line of force radiates from a unit of surface of a sphere of unit radius may be comprehended so far as the unit is concerned, but has not the slightest applicability in practical work. The conception causes great difficulties in the minds of students"—as well it may. The conception which we should like to see adopted, that unit pole is that produced by one line of force, on the other hand though interfering with the balanced theorisings of mathematicians, would lead at once to simple explanations of most of the ordinary phenomena of magnetism and induction. The metre itself, as Mr. Emery remarks, and we should do well to remember in these discussions, "is nothing more or less than the distance between two marks on gold plugs on a platinum bar," even as our own yard. He adds, "It must not be thought that the use of absolute measure in electrical formulæ for proportioning dynamos and motors secure absolute accuracy. There is apparently no numerical coefficient at the beginning of such formulæ which can be modified to suit the conditions, but allowances are necessarily made at another stage of the calculation, as the number of lines of exciting force must be 20 to 40 per cent. in excess of those used across the armature." He recommends the factor which Towle, engineer to the "Great Eastern," said should be embodied in every formula—K = common sense. There is a great deal in this, as every practical designer of dynamos well knows.

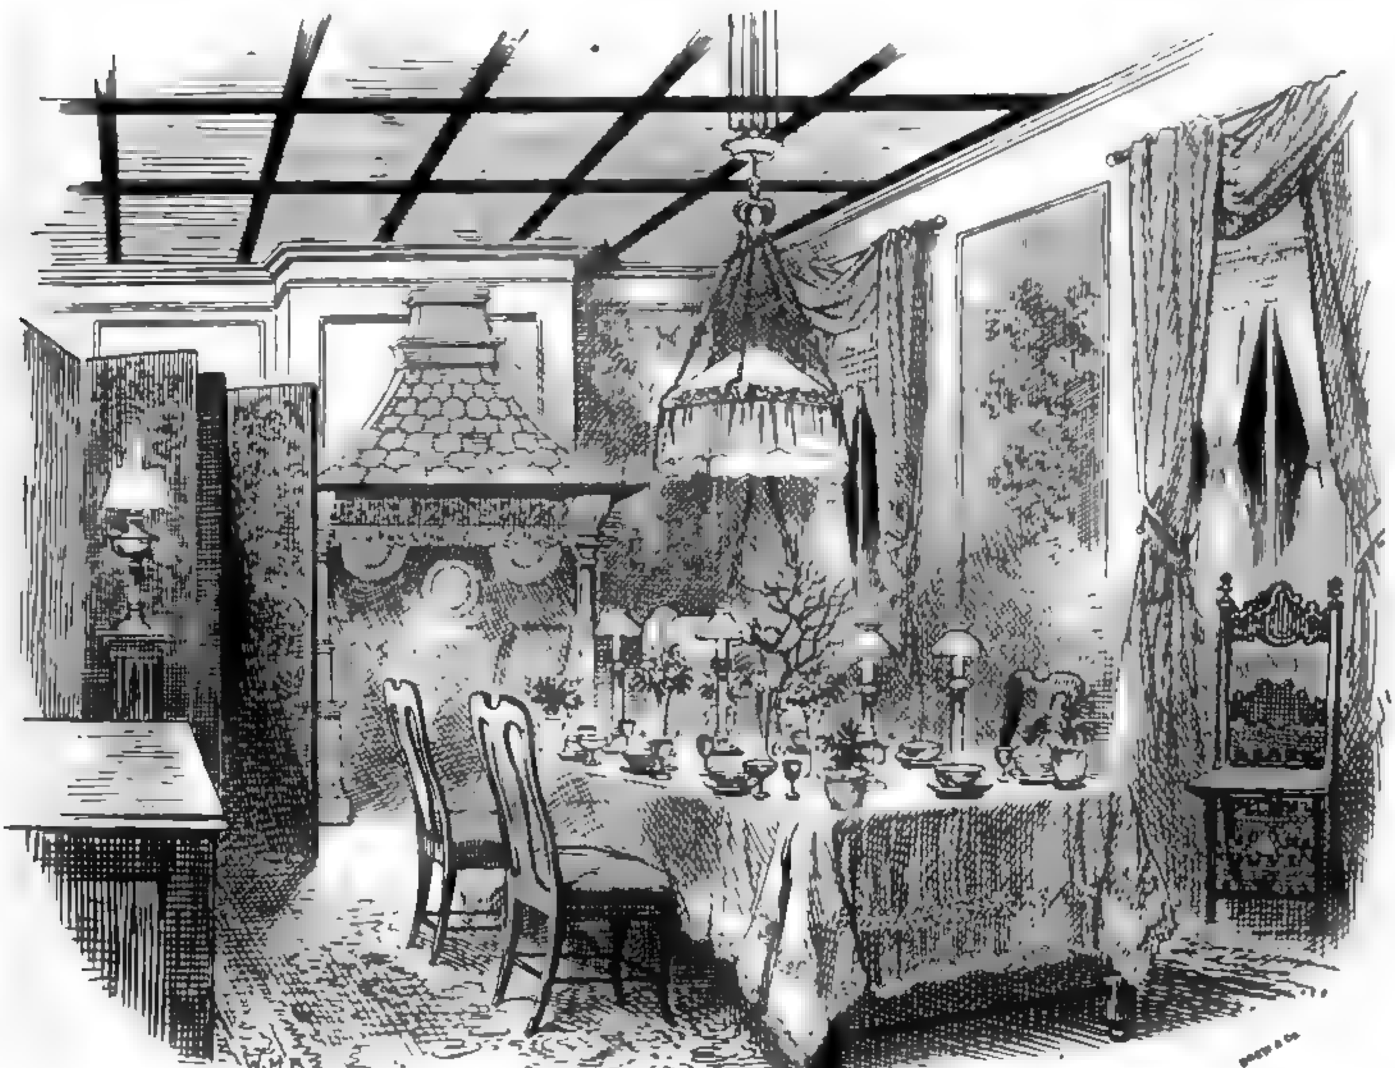
Rotary-Current Plant.—A complete "Drehstrom" plant is now being installed for experimental testing at Messrs. Greenwood and Batley's rooms in Albany-mansions, Victoria-street, and has already been visited by many electrical engineers. The plant has been brought over from the Allgemeine Company, of Berlin, by Mr. Henry Edmunds and Mr. Reckenzaun, and installed in the rooms placed at their disposal by Mr. Blackwell, of Messrs. Greenwood and Batley. It has already undergone some interesting tests at the hands of Mr. Kapp, and has been shown by him at his lecture to the Royal Engineers at Woolwich. The plant consists first of an ordinary continuous-current dynamo, driven as motor from the Westminster mains at 105 volts, the current after having entered the armature of this motor being taken off to ring collectors connected at points 180deg. from each other in the segments, this giving a three-phase current. The field magnets are excited by a separate wire from the mains, but the total current used, about 50 amperes, passes through a single ammeter. Both field and armature currents are controlled by resistances. The three-phase current is led first to a reversing switch, passing through the ammeter which registers one-third of the total current. This ammeter, when we visited the plant, showed 29 amperes. The voltage between any two of the three wires remains the same, and lamps can be lighted on any two of the wires. The pressure was 59 volts. The three-phase current passes to a small rotary-current dynamo having three collectors. In this particular specimen the current generates a rotating magnetic field in the armature, which, reacting on a laminated iron case surrounding it, rotates, and so drives another ordinary dynamo connected to the motor shaft. This dynamo lights 29 100-volt lamps. We understand that Mr. Kapp's tests showed the efficiency of the motor to be about 80 per cent. In the new form of motor which is being prepared, the rotating field will be induced in the stationary field magnet, and the armature will be a solid core dragged round by the rotary field. This form of rotary-current motor has the advantage of doing away with the need of collectors and brushes, the wires being connected direct to the motor. The motor starts under full load. The speed of rotation at full speed is not quite synchronous to that of the supply motor, but less a certain lag due to the mechanical friction. The plant is extremely interesting, as being the first installation of the "Drehstrom" motors in England.

THE CRYSTAL PALACE EXHIBITION.

The Exhibition is gradually approaching completion. Chaos is giving place to order, and in the machine department especially a vast amount of work has been done since our last issue. Almost all the stands have now machines in running order, and the variety of gas engines will prove a characteristic of the Exhibition. While, however, we may admire the diversity of this class of engines, and the eagerness to produce them shown since certain patents lapsed, the engineer will turn with greater admiration to some of the examples of steam engines at work. Messrs. Davey, Paxman, and Co. have finished the erection of the 250-h.p. engine driving Kapp's dynamo, and at the time of our visit it was running with great smoothness and without noise. Messrs. Easton and Anderson, too, are driving Prentice's dynamos with their engine. Crompton and Co. have a splendid specimen of Crossley's gas engine going. Siemens's are using Willans and Robinson's engines, and so on. Probably the Machine Room will be complete by the end of the month, when it will be well worth a careful examination. In the body of the building several stands are yet bare, some not even commenced, and in the galleries much still remains to be done by the art furnishers and decorators.

One of the characteristic features of this Exhibition will be found in the upholstering department. A variety of firms have furnished rooms with a special view to their being lighted by means of incandescent lamps. It has been remarked that visitors will probably prefer to wander among these luxuriously-furnished rooms rather than among the moving machinery in the Machine Room. It must be remembered, however, that if householders are to be induced to patronise the electric light, more will be done by showing ready-fitted suites of rooms than by showing dynamos; and it must also be remembered that the adoption of the light means the adoption of the dynamo. Hence we should all support the enterprise of those firms who have gone to the expense and trouble of showing how apt a means of illuminating handsomely-furnished and costly-decorated rooms is afforded by the incandescent lamp.

We have already referred more than once to the well-arranged exhibit of **Messrs. H. and J. Cooper,** designers and decorators, of 8 and 9, Great Pulteney-street, W., which will be found at Stand 203 in the South Gallery. Owing to the fact that the suite of rooms shown by this firm was complete down to the smallest detail on the opening day, we are able to give a description of them in our present issue. Later on we shall hope to publish some sketches, which will give an idea of the design and decoration of the different rooms.



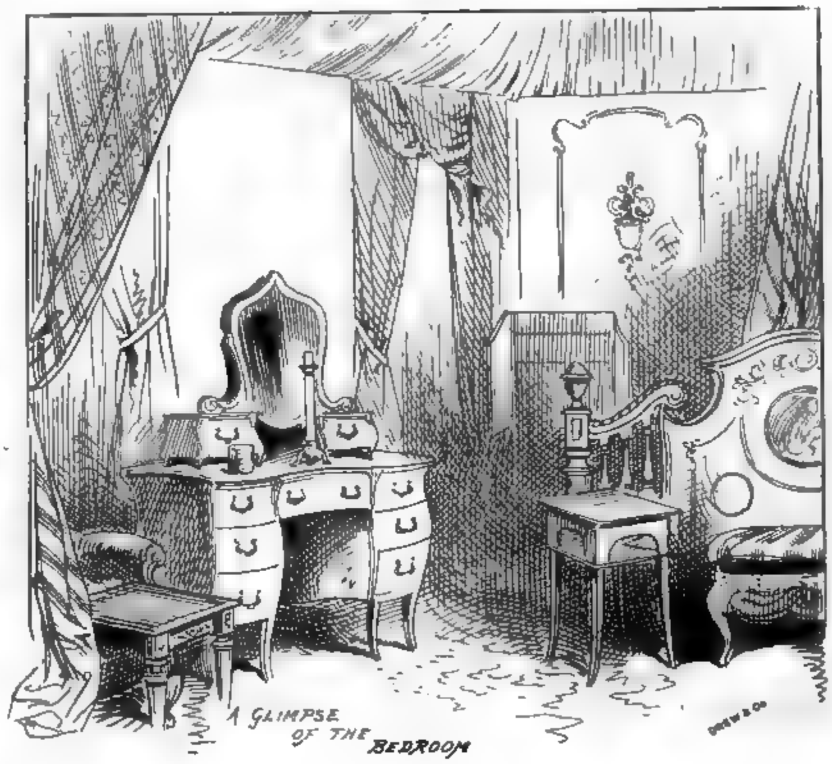
The Dining Room.—Messrs. Cooper's Exhibit.

Though the suite has been erected with great care and completeness of detail, the exigencies of space and position have, as in the case of a theatrical stage, made it necessary to play some tricks with actualities. So we enter through a handsome grilled screen of wrought iron, which is worthy of more than a cursory glance, and make our exit at the other end of the suite, through a draped archway, whose existence is easily blotted out by a slight effort of the imagination. The suite consists of a dining-room, boudoir and bedroom, each decorated and furnished in a different style. We will begin with the dining-room, the dimensions of which are 22ft. by 15ft. It is a handsomely furnished room with two delicately-draped windows overlooking the Winter Garden. The table in the centre is laid and looks provokingly tempting. At the end by which we have entered is the fireplace, arranged as an ingle-nook, of carved oak in the Early Renaissance style. In the recess of this nook are cosy seats covered with

Genoese velvet in Venetian design. Incandescent lamps in the corners give a mellow light, and with a bright fire on the hearth this would be just the place for building castles in the air, or for a *tête-à-tête* with some congenial spirit. The walls are panelled with pictures of the Flemish school, whilst the windows are flanked on either side by armour, which has a novel and striking effect. Near the ingle-nook is an old-fashioned armchair, a reproduction of the eighteenth-century style, and marvellously comfortable for bones of all ages. The chairs placed round the dining-table owe their design to the times of good Queen Anne, and are light and graceful in appearance. Opposite the fireplace are massive carved oak entrance doors, surmounted by a pediment carved with much spirit. The floor, of patent removable parquet, is covered with a fine Anatolian carpet. The table, which, as we have intimated above, is laid for dinner, is furnished with Venetian glass, and seasonably decorated with mistletoe. The centre-piece consists of a frosted branch of hawthorn with bird and, if we mistake not, nest also—which is not quite in accordance with the usual course of things natural. The table is lighted by candlesticks fitted with imitation candles carrying incandescent lamps, and by other lamps ranged round the room so as to light the pictures. Taken as a whole, when lighted, this room has an appearance of cosiness and warmth which draws frequent exclamations of delight from visitors. Everything is tasteful and harmonious, and the lights are judiciously placed so as to give a good effect without intruding themselves on the eye.

From the dining-room we pass into an Oriental boudoir, which will assuredly excite covetous feelings in the breast of many a fair visitor to the exhibition. Exactly opposite us as we enter is a plaster cast reproduction of an Arabian niche, such as is usually placed in Eastern mosques to denote the position of Mecca. This niche, with its gorgeous gilding, surmounts panels of rare old Persian tiles of antique colouring. To the left of the niche is a specially designed window in the Arabian style, the powerful colouring of which has been most harmoniously blended. In another corner are divan seats with a canopy of rich silk, upheld by inlaid Persian spears. The seats are covered with fine embroidery and provided with embroidered cushions. In the wall close by is a beautifully designed Arabian panel of very fine lattice work. A large wall panel of plate glass, overlaid with gilt palm fret, adds much to the beauty of the room. Beneath it is a seat in embroidered Moorish work, which is flanked by a pair of very fine Persian candlesticks of pierced brasswork, standing some 4ft. high. Near the canopied divan stands a coffee-table with a top consisting of one large circular Persian tile, the colouring of which is lovely. A second coffee-table of Damascus work, inlaid with mother-of-pearl and silver, stands in another corner of the room near the Mecca niche. The Cairene apron-piece of the room has a tented roof, in keeping with the Eastern character of the furniture and decorations. The boudoir is lighted from reproductions of antique Arabian vases hanging from the apron piece. The floor is covered with matting, over which are laid rugs and mats. In truth 'tis a room wherein to listen to the 1,001 nights, or whisper into sympathetic ears those soft nothings which mean so much—a room full of rich colour, and yet a room in which a tired mind and aching eyes might well find rest.

From the boudoir, a doorway, the soffits of which are supported by beautifully carved stalactite brackets, the whole being draped with gold silk gauze, leads to a bedroom, which may be termed an English rendering of the Louis Quinze style. From the exclamations escaping visitors of the fair sex on entering this room, we may take it that "lovely" and "exquisite" are the proper terms to apply to it. The principal decorations are in salmon and white. The ceiling consists of a large oval centre, hand-painted with cupids, after Boucher. From this centre-piece falls a silk draping which reaches to the top of the walls, somewhat after the manner of a tented roof in the French style. The bedstead is white with *carton pierre* decoration, the centre panel at the foot bearing hand-painted cupids in the same style as the ceiling centre-piece. The head is surmounted by a canopy nearly reaching to the ceiling, of salmon silk with overdrapery of white muslin. This canopy is caught up by two cupids, while a third tiny fellow flying in mid-air holds an incandescent lamp. The coverlet consists of a handsome piece of embroidery, bordered with plain figured silk. By the side of the bed stands a compact little writing-screen, available for the composition of those mysterious missives usually known as *billets doux*. When not used for writing it folds up into a screen. Messrs. Cooper have submitted one of these screens to the Princess of Wales. The dressing-table is of a novel and very elegant design, with bevelled mirror, also of uncommon design. The draperies of the windows consist of salmon silk, the valances of which are embellished by gold darts. The fireplace is in mahogany, with Bartolozzi engravings let into the panels, and fitted with a handsome pierced and chased brass fender. On the other side of the room is a special



A Corner of the Boudoir and Bedroom.—Messrs. Cooper's Exhibit.

fitment introduced by Messrs. Cooper, with the idea of doing away with much movable and bulky furniture in the shape of wardrobes, chests of drawers, and so on. The fitment contains wardrobe, drawers, shelves for books, etc. The frieze over the wardrobe is ornamented with hand-painted lunettes in the same style as the ceiling and the bedstead. The door leading out of the room is of mahogany, the two upper panels having Bartolozzi engravings with gilt mounts, and is surmounted by an overdoor with *carton pierre* decoration and more engravings. The door furniture is of pierced brass. In one corner stands an elegant easel, which the designers have named the "Princess Christian," after her Royal Highness. Messrs. Cooper have supplied these easels to members of the Royal Family. The floor is covered with a Moquette carpet in Louis Quinze style, with blue centre and cream border. Finally, the lighting of the room has been carried out with considerable thought and care, as, indeed, is the case with the other apartments we have described.

Comparisons are notoriously odious, but we are relieved of any necessity for making them by the fact that Messrs. Cooper had their exhibit complete in every detail on the opening day, and were alone in this respect. Therefore no comparison with other exhibits could be made, if we were inclined to institute one. Of this, however, we are assured—viz., that electrical engineers should be grateful to this enterprising firm for showing how beautifully the incandescent light is adapted to the lighting of rooms furnished and decorated with all the taste and skill which has been lavished on the suite we have described. We trust that Messrs. Cooper may reap the substantial reward they so well deserve.

One of the largest and most important exhibits in both Machinery Department and Main Transept is that of **Siemens Bros., Limited**, and it will, we think, be not only intensely interesting to electrical engineers, but also one in which public interest will be most largely kept up. This will accrue from the exhibition of the model electrically-lighted theatre, which was shown in Frankfort; the daily demonstration is to be given of telephonic curves and tones and an analysis of the interior working of the telephone; the manipulation of a 50,000-volt current, strong enough to pierce ebonite 17 mm. or glass ½in. thick, or give an arc of 12in. across water, or light 500 100-volt lamps in series; a new type of transformer in the form of a length of thick cable; an electric winch, electric passenger and dinner lift in working order, to say nothing of the ordinary sight of Siemens dynamos in working, motor-dynamos, electric tools, a new system of automatic block signalling for railways, automatic electric mine exploders, besides telegraph and cable instruments in profusion. It is perfectly evident all this cannot be described in one article. We must begin with a cursory review of the salient features in their order. In the first place—the dynamos. At the Machinery Hall we see one of the large Siemens continuous-current dynamos, designed for 120 volts and 1,600 amperes at 350 revolutions, the ordinary standard type of dynamo for central station work, as shown at the Naval Exhibition. Three of these were there used, and all of them have been since sold to the St. James's and Pall Mall Company. This dynamo is not shown running. Of the working plant, we see an H B Siemens bar armature dynamo, continuous current, for 120 volts and 450 amperes, at 420 revolutions, as used for shiplighting, driven by a Willans and Robinson closed type of engine, of 75 i.h.p. Another dynamo of the same type, working in parallel, giving 120 volts and 200 amperes, at slower speed, 320 revolutions. This is driven by an open-type Scott, Willans, and Robinson engine. A fourth dynamo is a Siemens alternator, not running, shown coupled direct to a Tangye engine, making a "ship set," as supplied to the P. and O. boats, giving 105 volts 200 amperes at 200 revolutions. A fifth dynamo is an alternator, which will be used for supplying current for the high-tension experiments; these are to be ready at the end of the month. The dynamo supplies 80 volts 500 amperes, driven at 420 revolutions by a Willans G G engine. The current will be transformed up first 80 to 2,500 volts by the new "cable" transformer, and then again by the large Siemens 50,000-volt transformer. This is the highest ever attempted by a dry transformer—*i.e.*, not immersed in oil—and is five times that of the Deptford transformers. It will give a spark of 2in. in dry air. The capacity of the transformer is two amperes and 50,000 volts, or 180 h.p. In one corner of the exhibit is an electric winch, which will lift five tons 90ft. a minute. The motor is so arranged that the load can be suddenly arrested without affecting the armature. The efficiency is 93 per cent. Specimens will be shown of electric drills intended for piercing the sides of ships, the frame of the drill holding on to the ship by its own magnetism. This will be shown in action, as also ventilators, brushes, and other electric tools. A passenger lift to carry 10 persons, made by Waygood, has been fitted with complete electric gear, and will be working, raising visitors to the gallery. A dinner-lift will be in operation close beside it. The transmission of power will be also shown by a motor-dynamo, or continuous-current transformer, 100 to 800 volts. This will supply current to the block system signals. These will be of great interest to railway engineers. They consist of cast-iron sleepers carrying the rail, containing contacts depressed by the weight of the engine; the engine thus automatically blocks its own line. Another application of the motor is that of an electric fire engine of 30 h.p., Messrs. Siemens's own design. It will throw water by electricity instead of steam, by being connected to the street electric mains through contacts fixed near the standpipe. The show in the Transept contains several arc lampposts, a tall lattice mast carrying six arcs for lighting large areas, and four posts for street lighting. Messrs. Siemens have also six large arc lamps outside the turnstiles. Two large showcases contain some magnificent specimens of their electric cables, concentric and single conductor. One of the latter contains 1,000 square millimetres. The "cable" transformer mentioned is a novel piece of electrical apparatus. It consists of a huge piece of cable about 5in. diameter and 10 yards long, like a great hosepipe. This is the transformer; it has a flexible iron core and two copper windings. The length regulates the voltage, and they can be cut off in lengths to requirements. The one shown is to transform 2,500 to 80 volts, and of great capacity—500 amperes. Smaller ones for house lighting could be inserted in the main or hung up in a cellar. The model theatre is arranged in the Pompeian Court. Here miniature stage effects will be shown—sunset, Alpine glow, moon effects, sunrise, lightning, and so forth—all electrically produced by incandescent lamps and electric motors, and controlled by one man at one switchboard, placed on full view in front of the stage. We have said enough to show the interesting nature of Messrs. Siemens's exhibits; further details must be left for future description.

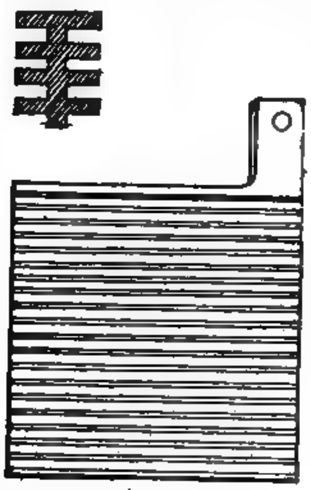
Conspicuous in the North Nave is the stand (No. 117) of **Messrs. Benham and Froud**, of the Chandos Metal Works, Chandos-street, Strand, W.C. Here are shown specimens of very high-class metal work in the shape of electric light fittings, both for public buildings and private houses. Among the examples exhibited are: A large nine-light brass electrolier, the arms of which are repetitions of brackets recently made for the ballroom, Government House, Rangoon; an electrolier, with corresponding wall lights, mirror bracket, etc., in finely-chased mercury-gilt work; an electrolier, silver-plated in the style of Henry IV. of France; a silver-plated bracket, a replica of those made for the Royal room, Lyric Theatre; two ceiling lights in copper and brass, representing (1) a bouquet of flowers, (2) a group of fan palms; a bracket as now in use on the stage at Terry's Theatre in "The Times"; a wall light of quaintly-embossed copper, in the form of an owl, the lamps being introduced within the repoussé work; a number of ceiling lights, electroliers, brackets, table pillars, girandoles, floor lamps in gilt, silver-plated, copper, brass, hammered iron, etc., the whole of which have been designed for, and manufactured at, the Chandos Metal Works. A model is shown of the ball and cross on St. Paul's Cathedral, made at these works, A.D. 1821, and adopted as the company's trade-mark. Above the stand are examples of weather vanes with lightning conductors attached.

In the Mediæval Court, Messrs. Benham and Froud have fitted up a representation of the east end of a very modern church, which is lighted electrically. We shall

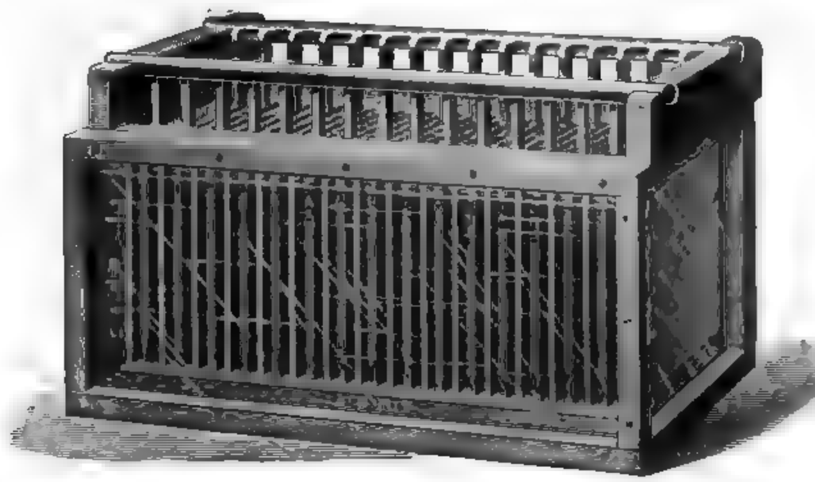
Specimens of Messrs. Benham and Froud's Electric Fittings.

describe this exhibit fully in another issue. Meanwhile, we give illustrations of some of the Chandos fittings.

The Epstein Accumulator Company, Stand 9, are exhibiting their make of secondary batteries. It may be remembered that this is a modified Planté battery; the formation of the plates is obtained by placing them in a 1 per cent. solution of nitric acid and water. We remember having tried this method of formation in 1882, but failed to obtain satisfactory results; hence credit is due to those who have overcome the difficulties which haunted the earlier experimenters. If we remember rightly, one insuperable difficulty to us was that using flat plates we got an excellent formation, but in a very short time the formed surface stripped from the unattacked lead backing. Mr. Epstein uses a slotted plate, and contends he obtains by his process a firmly adherent coating. His forming solution is heated till it boils, and the boiling continued till the plates present a dull grey appearance. After which they are dried in the air. Lead treated in this manner is made to serve for both positive and negative plates. In the process of forming positive electrodes, the former greyish-yellow colour changes into a deep dark brown, almost a bluish-black hue, and the process is completed as soon as the elements have attained that colour and an abundant development of oxygen has taken place. The oxygen of the peroxide of lead produced on the positive elements which are to be changed to negative is absorbed by the effect of the electric current, and the bodies are reduced on their surface to porous metallic lead. The process of forming negative elements is finished when the deep dark brown, or bluish-black colour of the positive element used for the purpose has changed into a bluish-grey hue. It is said that only a few hours are necessary to form a plate by this method.



Epstein's Element.



Epstein's Secondary Battery, R 31 Type.

In Epstein's form of electrode, which exposes a large surface, and which, when treated by his process, is said to quickly acquire a considerable electrical capacity, the increase in surface is obtained by deeply grooving both sides of the plate, as shown in elevation and section in our illustration. The soft active material, after being "formed" is said to key itself between the ledges, and it does not appear to fall off even if the battery is roughly used. From figures supplied by the manufacturers, Messrs. Woodhouse and Rawson, the following table has been compiled:

Mark and number of plates.	Weight of plates.	Approximate external dimensions of box.			Working rate.		Capacity, Amp.-hours.	Approximate weight of complete cell.
		Length inches.	Width inches.	Height inches.	Charge. Amp.	Discharge. Amp.		
R 3	52 lb.	15	3¼	17	1 to 30	1 to 30	120 to 150	81 lb.
„ 5	100 „	15	5¼	17	1 „ 60	1 „ 60	240 „ 300	155 „
„ 7	150 „	15	7½	17	1 „ 90	1 „ 90	360 „ 450	225 „
„ 9	200 „	15	9¼	17	1 „ 120	1 „ 120	480 „ 600	295 „
„ 11	250 „	15	11⅛	17	1 „ 130	1 „ 150	600 „ 750	368 „

The normal maximum rate of discharge is given as 30 amperes per positive plate, and for short periods this rate may safely be doubled. The capacity at the above rate of discharge is about 120 to 150 ampere-hours per positive plate; at half this rate the capacity is about 140 to 170 ampere-hours per positive plate. The liquid used is a 10 per cent. solution of sulphuric acid and water.

Our illustration shows one of the R 31 type, as shown at the Palace. Other lighter and cheaper cells are manufactured, as will be seen by an examination of the lists of the company.

Messrs. F. Wiggins and Sons, mica merchants, of 10, Tower-hill, and the Minories, E.C., have in the South Gallery one of, perhaps, the finest exhibits of mica that has ever been shown. It is evident that the firm have spared no pains in preparing and arranging their stand, and, to their credit, be it said, they were ready from the first. Here will be seen some magnificent mica slabs, both in size, colour, and geographical origin. They are from all quarters of the world—viz., Bengal, Madras, Ceylon, Brazil, North America, Canada, North Carolina, Labrador, Guatemala, etc. The colours of the slabs comprise what are technically known as ruby, pale green, amber, and black spotted, of which ruby is the most valuable. The firm also show mica worked up for different purposes, such as strips for dynamo armatures and commutators, a use for which it has been much employed of late; also turned washers, bushes, compass cards, lightning protector strips, and lamp chimneys. In a corner of the showcase a column of turned mica may be seen. Being composed of several different varieties, on looking through it the various colours are seen the reverse way of the layers, and very beautiful they look. This is a novel and interesting exhibit. We advise our readers not to leave the Palace without having a look at Messrs. Wiggins's stand in the South Gallery.

Messrs. Johnson and Phillips' exhibit will excite considerable attention. Conspicuous among the many conspicuous objects at this Exhibition are the buoys shown by this firm. It must, however, be with the less prominent objects that we commence our examination of this stand. One of the best known arc lamps of the day is that of Brockie-Pell, manufactured by this firm. Specimens of these lamps hang all round the stand, and externally have the appearance shown in the accompanying illustration. From the point of view of the purchaser, this lamp is recognised as burning steadily, and giving a minimum of trouble. One of the most recent departures of this firm is in the manufacture of secondary batteries, they being the manufacturers of the D.P. cells for Messrs. Drake and Gorham. These cells are illustrated herewith. The plates are formed on the Dujardin process, and are rendered active by a combined depositing and oxidising action performed by electrolysis in an alkaline bath of nitrates composed as follows: Ten kilogrammes of water, two kilgrammes of sulphuric acid, one kilogramme of alkaline nitrate (of soda, ammonia, potash, or other suitable alkali).

By the passage of an electric current nitrate of lead is formed, and by the acid of the bath this is converted in a continuous manner into sulphate of lead and afterwards into peroxide of lead. In some hours, without discharging or reversing the current, the positive plates become covered with an adherent layer of crystalline peroxide of lead, which may be over a millimetre thick, and of great electrical capacity. In order to increase and regulate the formation of the salts of lead, it has been found that it is useful to introduce large volumes of air into the liquid. This may be effected either by forcing the air into the bath, by raising and lowering the plates, or by other convenient means; the reaction being thereby doubled whatever may be the composition of the bath. In order to facilitate the adhesion of the peroxide upon the plates, the latter are constructed of laminated lead. In a few hours the peroxide, which is formed at the expense of the lead, fills the interstices in the laminated plate. A systematic description of the exhibits will naturally group around three heads—cable apparatus, which includes buoys, grapnels, hauling gear, etc.; electric light generating apparatus, into which come prominently the various Kapp dynamos; and electric light apparatus generally, including storage batteries, transformers, mains, switches, etc. Of all these more anon.

At Stand No. 2 we find the exhibits of **Messrs. Swinburne and Co.** The name of Mr. Swinburne is well known to all electrical engineers, and his all-round experience is pretty extensive. Cradled in the works of Mr. Swan, at Newcastle, his knowledge of all that concerns lamps was obtained at first hand. Afterwards, in this field, he attempted to walk alone, but found it better to associate himself with the firm of Crompton and Co., where he necessarily gained large experience in dynamo work. Mr. Swinburne paid special attention to transformers and measuring instruments. Commencing business himself, he made a speciality of the form of transformer which has been named the "Hedgehog," because of the loose wires at the ends, which remind one of the bristles upon the back of one of the innocent denizens of our hedgerows.

As might be expected, then, this firm exhibits a number of Hedgehog transformers. These transformers have been the subject of so much discussion that little need now be said about them. The makers claim that in designing closed-circuit transformers engineers have neglected the loss of power in the iron, and that as the loss in the iron goes on all day and all night it is really very serious. They, therefore, make a transformer which has very little iron, for which they claim a much higher all-day efficiency. This advantage cannot be obtained without some drawback. The drawback generally urged in this case is the idle current taken on open circuit. This does not represent power, but it may be in some other respect troublesome. Though the makers have never found this idle current give any trouble in central stations, they have foreseen that there may some day be difficulties, and have therefore set to work to bring out commercial alternate-current condensers, which will be described separately. The ordinary transformer, with its case, is illustrated herewith. In addition to the ordinary transformer for housework, special designs for other purposes are shown. Two forms of street lighters are exhibited. One is the ordinary form with the stoneware case replaced by a light cover made of roofing material. This is arranged to fix on posts for town lighting, as at Chelmsford, or to attach to walls as is usual in America. Each transformer feeds into a low-pressure circuit which supplies a number of lamps. This form is also used for arc lighting. In this case constant-current transformers are used. These take 2,000 or 100 volts on the primary, and give 10 amperes on the secondary. The trouble and expense of secondary leads is entirely done away with. It is needless to say that an arc lamp will always burn more steadily with a constant current than under constant pressure, and this condition is much more easily obtained with alternate than direct currents. In direct-current work it is usual to run special arc circuits, or else to couple arc lamps in pairs in series with resistance. In alternating-current systems, one high-pressure parallel circuit can supply everything.

For incandescent street lighting, Messrs. Swinburne and Co. exhibit a fitting which consists of a small transformer with case, shade, and lampholder complete. This takes 2,000 or 1,000 volts, and has a 50-volt 32-c.p. lamp. The object of this arrangement is to admit of street lighting with incandescent lamps without special secondary leads. In fact, it is very much as if Messrs. Swinburne and Co. had brought out incandescent lamps for 1,000 or 2,000 volts.

1892.

We had intended to conclude the review of the past year with our last issue, but space was required for more pressing matter, hence one or two questions upon which it is desired to comment remain till now. A sane man reading the ephemeral literature of the day, as represented by the great London dailies and the metropolitan and provincial weeklies, can hardly realise that this is a time forming part of a civilised era. At a moderate computation, one-half the papers are dependent for existence upon quack advertisements, plus those emanating from swindling company promoters. Of the latter we have often spoken, of the former we have still to speak. There is a tale told of two men walking down a street, one a qualified medical practitioner, the other a quack doctor. The former asked the latter why the public deserted him with all his learning and experience to patronise the disciple of nostrums. Said the latter: "Your question may be best answered through another, How many men possessing a fair share of common sense should you imagine to exist? Say per cent?" "About 5 per cent.," replied the qualified practitioner. "Well, those five are your patrons, the rest mine," said the quack; and this, no doubt, is pretty near the truth of the case. The nostrums advertised find purchasers—yea, and purchasers in large numbers, otherwise the quantity of advertising would be lessened. For many years quacks have sought to qualify their productions by the adjective "electrical." Every ailment under the sun is, according to them, to be cured by something "electrical," or something "magnetic," which terms for the nonce may be taken as identical. Those who possess a rudimentary knowledge of electrical science know that nine-tenths of the statements made by these advertisers are altogether inaccurate. For the moment let us refer to another subject which runs on parallel lines to the above. The editors and the news purveyors to the papers are supposed to be men of light and learning, to be men who desire to leave the world in a better and a happier state than they found it. Of course we assume that the first object is to make their pile. Well, what is the position of these learned purveyors of mental pabulum? Just this—that the most atrocious statements are propagated with regard to matters electrical, that a lie about such matters is more likely to be believed than the truth. Men are led to expect what they ought never to have been led to expect, making it necessary in the interests of progress to first eradicate the false before a lodgment can be given to the true. The most mendacious statements come over here, for example, ticketed with the labels of news agencies, from America. The senders of the telegrams ought to be electrocuted; in fact, that punishment is too good for them—it would require a Dante to suggest a suitable one. Talk about a lying spirit being abroad; that is but a mild expression. Here is a sample of the latest. Edison—and, mind you, these purveyors always imagine their "copy" must be taken if they can bring in the name "Edison"—is said to have discovered a way by means of which a "score or so of men" can defend a fortress against an

army by using a jet of water. That statement has been read by tens—even by hundreds—of thousands of scientifically ignorant readers, and, like all nostrums, eagerly swallowed. One would think it was a difficult task to ordinarily fill a newspaper with reading matter, instead of the difficulty being how to deal with too much matter. Every electrical engineer knows what peculiar pranks young electricians have played, and how men have danced and ejaculated with amusing verbosity when undergoing these practical jokes, but there is not one man amongst them but knows the absurdity of such a statement as the above. We wonder at the dissemination of such silly tales from a politician's point of view. If defensive works are necessary, say those who read these items, why not employ the cheap and efficient method "we are told a celebrated electrician has discovered"? Why spend money upon huge works, upon guns, and upon a standing army? By the bye, reader, did you ever try to disabuse anyone's mind of the untruthfulness of such statements? If not, pray try it.

Here, then, are two directions in which the efforts of the technical press are neutralised by the crass stupidity of those who arrogate to themselves the sole right of belonging to the "journalistic profession." They permit quacks to entice the public to buy and use nostrums, and they carelessly or wilfully permit their columns to be the vehicles for the propagation of the most astounding electrical paragraphs that the mind of man can invent. One of our contemporaries in England has made, and often repeated, attacks against electrical quackery, but its efforts must fail, because its readers are not those to be easily caught, and those easily caught are not among its readers. What is the use of a parson declaiming to those present forming his congregation about non-attendance? It is the editors of the dailies and weeklies who hold in their hands the power to suppress quackery, but they won't use it because the quacks advertise more than all other people combined. *Hinc illæ lacrimæ.*

Having said this much, we will add to the list of firms noticed that of—

J. D. F. ANDREWS AND CO., which, during the past year, had made rapid progress with the system of concentric wiring, and has carried out many important installations on this system in London and the country, the most important of which are the Waterloo grain warehouses, with 200 50-c.p. lamps, and the Park-hill petroleum stores, with about 100 16-c.p. lamps, and three of 300 c.p., the dynamo being about one-third of a mile distant. Another important installation is that of the Tyne Theatre, Newcastle-on-Tyne, where there are 200 16-c.p. lamps, and six of 200 c.p. As a proof of the great success of this system, Messrs. Andrews and Co. have already concluded three contracts for the Mersey Dock Board, Liverpool. The system may be examined at the firm's offices at 41, Parliament-street, where they have an installation of 100 lights connected to the mains of the London Electric Supply Corporation. The majority of the insurance companies have had the system under their consideration, and have drawn up a set of rules which give latitude for its introduction.

BLAKEY, EMMOTT, AND CO. state that it is not generally known that during the last twelve months the electric light has been installed in many of the public buildings, shops, and residences in Preston. A temporary generating station was fixed twelve months ago for the purpose of ascertaining what inclination the people of Preston had for the electric light. The National Electric Supply Company, Limited, which company obtained a provisional order for lighting the town for a term of forty-two years, intended that the maximum output for this station was to be only 1,000 8-c.p. lamps, but long before the plant was working the amount of lamps was greedily taken up on a basis of 12s. per lamp per annum. The company, to meet additional orders, were compelled to fix another machine, bringing the capacity up to considerably over 2,000 lights, which are now actually working, and orders for more daily coming in; but with the before-mentioned plant it is impossible to execute the further orders. They are, therefore, being filed for future connection from the central generating station which the company have now commenced to erect. The outside wiring has been overhead, there being four circuits from the central station in Corporation-street, two along pole routes through the most important thoroughfares in the town, and two over house tops, telephone fashion. The whole of the wires and cables for this undertaking have been manufactured by the Northern Electric Wire and Cable Manufacturing Company, Limited, Halifax. The present plant supplied by Messrs. Blakey, Emmott, and Co., Limited, of Halifax, consists of three dynamo machines of 18,000 watts; and a dynamo of 30 kilowatts has been specially designed for this station. It gives an output of 140 volts and 430 amperes, at 350 revolutions per minute. The magnetic system is octagonal in shape, with four internally-pointing poles. The yoke is of the best cast iron, and the magnet bars of wrought iron. The four magnet coils are wound upon four metal formers with brass cheeks, and can be readily removed or put in place. The armature is the cylinder type, and is built up of thin charcoal iron washers, carefully insulated from each other and mounted on a gunmetal spider. The diameter of the armature core is 21in. It is insulated with mica before being wound. The windings are laid on Gramme fashion, and consist of 200 turns of copper tape in 100 sections of two turns each. Nine driving horns of stiff vulcanised fibre are provided, which run the whole length of the armature. The windings are securely held in place by bindings of phosphor bronze wire. The commutator is made up of hard-drawn copper bars insulated with mica, and is carried upon the shaft by means of brass rings and fibre insulation. The armature connections are soldered to spokes projecting from the commutator segments. These spokes are afterwards covered by a disc of thin fibre, which not only prevents dust from lodging, but also promotes a strong draught through the armature from the pulley end and expels it at the commutator. Four sets of three brushes each are used, mounted on an adjustable rocking frame. The brushes are connected by four separate connections to the terminal-boards. The brushes are of gauze. The shaft is of Bessemer steel, and runs in long bearings of gunmetal. Sight-feed lubricators and oil-draining arrangements are provided. The magnet yokes divide in a horizontal line, and by raising the top half of the magnets the armature can be examined in place. This dynamo runs entirely without sparking or overheating, and notwithstanding the magnets are only shunt-wound, the lead given to the brushes has only to be altered a few degrees for any output from no load to full load.

The machine is the usual 90-kilowatt, or 3,000 lamps of 8 c.p., run at its ordinary speed of 500 revolutions, at which output it has an electrical efficiency of 97 per cent., and a commercial efficiency of over 93 per cent. For this output the armature is drum-wound with special end connections. The National Electric Supply Company, Limited, now propose to put down a plant on the low-tension system similar to that now working so successfully in the St. James's district in London, which Messrs. Latimer Clarke, Muirhead, and Co. have pioneered. The first portion of the town to be served from this station will be the compulsory area with the adjoining streets, in which it is sanguinely anticipated that a demand for at least 20,000 8-c.p. lamps will be made. Distributing-boxes will be laid in such positions as to ensure an even potential over the mains. A large number of meters have been successfully introduced, and it is the intention of the company to continue the supply. The amount charged to consumers is 8d. per Board of Trade unit, with a discount of 15 per cent. if paid within twenty-one days. The firm find by experience that this compares very favourably indeed with the cost of Preston gas, which, by the bye, is 2s. 9d. net, and of very bad quality. Preston, with its numerous mills, is favourably placed for a successful adoption of the electric light, and the way in which the present engineer and manager, Mr. F. F. Bennett, has worked up the present installation augurs well for the future. The Halifax Mutual Electric Light and Power Company, Limited, are continuing to do good work in the way of public lighting in the town of Halifax. It is nearly two years since this company was formed by taking over the central station then being worked by Messrs. Blakey, Emmott, and Co., Limited, and also that of an opposition company, which has since ceased to exist. The wires, by permission of the Halifax Corporation, are all overhead, and the company is supplying current for about sixty arc lights of ten amperes, and 1,000 incandescent lights of 8 c.p. Two systems of charging are adopted in the town—viz., one at the rate of 12s. per 8-c.p. lamp per annum, and £12 per ten-ampere lamp per annum, and at 8d. per Board of Trade unit. The furthest point served from the central station is about 1,700 yards. The low-tension system is adopted throughout. It has been found during the past two months that the company could not keep pace with the large demand for current at their present premises, therefore negotiations have been entered into with the Halifax Corporation for leasing from them a convenient site, and very shortly it is hoped that the company will have a capacity of at least 20,000 8-c.p. lamps. Two systems of engines are used for driving—viz., Armington-Sims's high-speed, and Tangye's. The dynamos and all other electrical fittings in connection with the installation are of the well-known Blakey-Emmott type, and Mr. Walter Emmott, of Blakey, Emmott, and Co., Limited, Halifax, is the managing director. The meters adopted up to the present have been the Aron, which appear to be giving general satisfaction, both to the Emmott Company and to the consumers. The price per 1,000 cubic feet of gas in Halifax is 2s. net, and judging from the weekly reports of the expert who tests the illuminating power on behalf of the ratepayers the average illuminating power is about seventeen candles. Taking into account this very low figure with high efficiency of gas, it speaks very well for the prospects of the electric light for the future when the present output and very large demand for current is considered. The whole of the wires and cables for this *installation* have been manufactured by the Northern Electric Wire and Cable Manufacturing Company, Limited, Halifax.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

STEAM ENGINE ECONOMY.

SIR,—We were interested in Prof. Ewing's report on the above. Some years ago we put up a large resistance (40 ohms) of very open iron wire spirals, for the purpose of testing alternating-current dynamos. From careful experiments we found that the current passing, as measured by a Siemen's electro-dynamometer, multiplied by the E.M.F., measured by a Cardew voltmeter, did not represent the electrical horse-power being given out. Indicator diagrams taken from engine showed that less horse-power was indicated in the cylinders than that in the external circuit, calculated as above.—Yours, etc.,

THE ELECTRIC CONSTRUCTION CORPORATION, LIMITED.
(T. Parker, Chief Engineer and Head Manager.)
January 19, 1892.

SIR,—In reference to the letter of Messrs. Willans and Robinson in your columns of last week, we would wish to state that it was not our intention to challenge record runs, and therefore in the tests made by Prof. Ewing no arrangements were made conducive to exceptionally high economies. These are the use of very high boiler pressure, and a separator or other means for obtaining very dry steam.

In the present tests the pressure at the engine never exceeded 75lb., and the steam was not dried.

It would be interesting to know with what steam pressure and engine Mr. Willans obtained the results stated by him at the meeting of the Institute of Civil Engineers last spring, for we are unable to find any mention of these two important factors in the *Proceedings* of the Institute.—Yours, etc., C. A. PARSONS AND CO.

Heaton Works, Newcastle-on-Tyne.

THE LATE ALEXANDER WATT.

We regret to have to record the death, on the 15th January, of Mr. Alexander Watt. The late Mr. Watt was the third son of Mr. Charles Watt, and was born in 1823. He was educated at Camden Town with a view to entering the medical profession, but in 1839 took up definitely the study of electro-metallurgy and electro-chemistry. From that time to the date of his death Mr. Watt was an indefatigable worker and writer. His books have been widely read, and his contributions on electro-metallurgic and electro-chemical subjects to the technical papers have been very numerous. His latest contribution, on the "Electrolysis of Gold Salts," was in course of publication in our columns. The late Mr. Watt cannot be said to have ranked as a pure scientist; indeed, the purely scientific was a phase of work which he scouted. His aim was always to get at something which could be put at once to a practical use, and for which he could obtain a practical recognition. A mere investigation with no practical end in view was to him a sheer waste of time and energy, hence his books and papers rather appeal to the working than to a highly-trained scientific circle. In all his work he was extremely cautious and painstaking, nor should one trait in his character be left unrecognised—his great and intense desire to see justice done to the labours of his brother.

Telegraph to China.—The *Times* correspondent in Burmah announces that the telegraph line is now almost completed between Bhamo and Nampoung Creek. The wires will then extend to within less than 100 miles of the terminus of the Chinese telegraph line in Momein. The Chinese authorities will be asked to continue their line and connect it with ours. An alternative telegraph line between England and China would be thus established.

THE DETERMINATION OF THE EFFICIENCY OF DYNAMOS.

BY GISBERT KAPP.

The power given out by a continuous-current dynamo, in the shape of current and pressure, can be measured with a very fair degree of accuracy. The ordinary commercial ampere and voltmeters now obtainable from good makers may be relied on to be accurate within a few per cent., and in some cases within a fraction of 1 per cent. In any case there is no difficulty in recalibrating the instruments sufficiently accurately to make sure that the error shall not exceed ½ per cent., so that the maximum possible error in computing the power need not exceed 1 per cent., and the probable error will be ½ per cent. Within these limits, then, we are able to tell what the output of any given machine is, and if we could determine with equal certainty the power mechanically supplied to the machine, the determination of the efficiency—that is, the ratio of electrical power given out to mechanical power supplied—could be made with a high degree of accuracy. But, unfortunately, the determination of power mechanically is not an easy matter, and is especially difficult when the power must not be absorbed by, but must be transmitted through the measuring instrument. Hence electrical engineers have very early in the development of their industry begun to cast about for some method whereby the efficiency of dynamos might be determined without making a mechanical measurement of power at all.

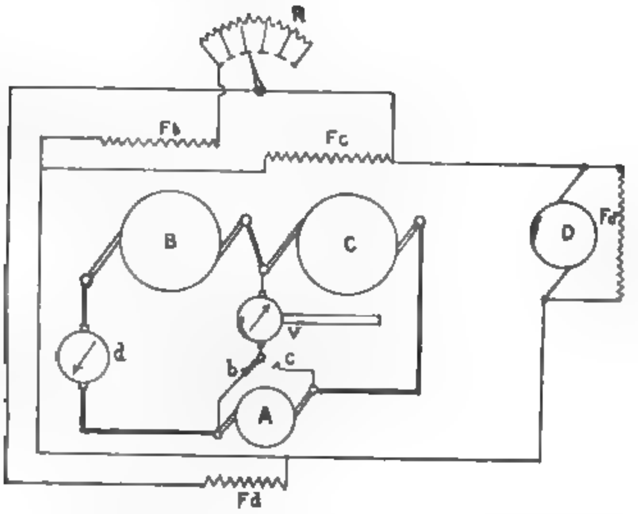

FIG. 1.

Probably the first to devise such a method was Major Cardew some six years ago, and his method was prescribed for dynamos supplied under his specifications to the War Office. To make an efficiency test three machines were required, preferably differing in output by the amount of power lost in each. The largest machine was arranged to supply current to the medium-sized machine, and that again was arranged to supply mechanical power by belting or direct coupling to the smallest machine. In order to work each machine at normal load their sizes must obviously differ. Thus, if A, B, and C be the three machines, and if B is rated as a 50-kilowatt dynamo, then it will work as a motor fully loaded if 50 kilowatts is supplied to it electrically. Its mechanical output, or the power it supplies to C, must be less than 50 kilowatts, because some power is lost in the machine itself. Say the net power available in the spindle of B is 42 kilowatts. We supply, then, 42 kilowatts to the spindle of C, and obtain from it again less power electrically, say 35 kilowatts. The machines will, therefore, be all working under full normal load if they are designed for an output of 50, 42 and 35 kilowatts respectively. Should B and C happen to be machines of equal size the test can still be applied, only B will be slightly overloaded and C will be slightly underloaded. This does not materially influence the accuracy of the test, since the efficiency of a machine is nearly constant for loads anywhere near the normal. The power supplied to A need not be measured; all we measure is the electrical power supplied to B and the electrical power obtained from C. The ratio between the two is the combined efficiency of B and C, and the square root of this ratio is the efficiency of each machine taken singly.

Another method for testing efficiency was devised some years ago by Dr. Hopkinson and shown to several engineers at the works of Messrs. Mather and Platt, Manchester. The improvement consisted in supplying not the whole of the power required by B (as in Cardew's test), but only the power lost in B and C, the current given by C being used to work B as a motor. In Hopkinson's method the two machines are mechanically connected, preferably by joining their spindles by a coupling. Over this coupling is placed a pulley, which takes the belt through which the waste power is supplied. In the arrangement adopted at Manchester the driving belt was passed through a Hefener von Alteneck transmission dynamometer, by which the power required to keep the whole system going was measured mechanically. The accuracy of this method is certainly greater than that of the direct method, where the whole of the power is measured mechanically, because an error in the reading of the dynamometer only affects the determination of the waste power, but some slight error may still occur. Say, for instance, that the efficiency of the two machines combined is 80 per cent. Then 20 per cent. of the power of one machine has to be supplied by the belt, and must be measured on the dynamometer. An error of

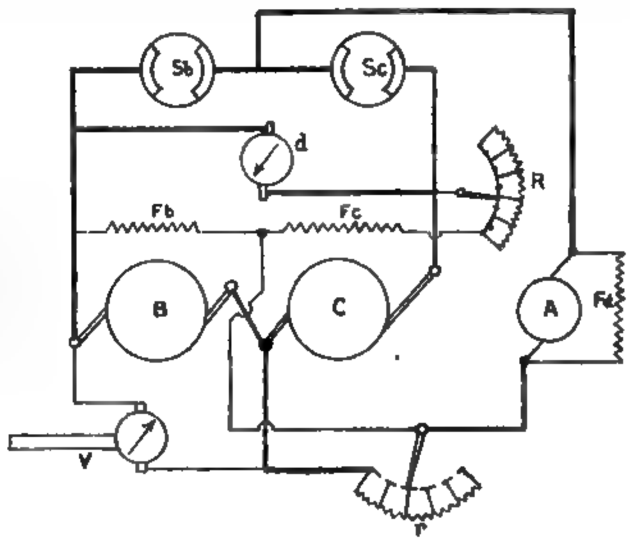

FIG. 2.

10 per cent. in this kind of power measurement may easily occur, and in this case the power supplied would be estimated at either 18 or 22 per cent., accordingly as the error is positive or negative, causing an error of about 1 per cent. in the final result. Apart from the inconvenience of having to rig up a dynamometer, there is the further objection that we must make the test by means of two totally different sets of measuring instruments which are not directly comparable with each other, and that it is therefore not possible to compensate the errors in the calibration of one set of instruments by those in the other set.

In this respect Cardew's test has an advantage. Not only do we use the same kind of instruments when testing the power supplied and the power obtained, but we can by a suitable arrangement of switches use absolutely the same instruments for both circuits, and then any calibration errors in one set of readings can be partially or wholly compensated by the errors in the other set of readings.

The objection to Cardew's method is that it requires the use of an engine and dynamo more powerful than any of the machines to be tested, and such plant is not always at hand or easily procurable. It is, however, possible to so alter the original arrangement that a comparatively small engine and dynamo will suffice for the testing of large dynamos. Using again the notation previously employed, if, instead of feeding glow lamps or resistance coils from the machine, C,

we let its current pass through B, and thus help working it as motor, then the machine, A, need only supply the difference between the power absorbed by B, and that delivered by C. We have, in fact, the electrical analogue to Hopkinson's mechanical method; and just as in this method a small belt suffices to keep a couple of big machines in motion at full load, so will here a small dynamo, A, suffice to keep a couple of large machines, B and C, working at full load. It is obvious that the connections between the three machines may be arranged in one of two ways. We may either put all the machines in series, in which case A must be a machine of low voltage and large current—*i.e.*, the same current as that for which the two big machines, B and C, are built; or we can place the three machines into parallel connections, in which case the small machine, A, must be of the same voltage as the two large machines, but need only give a small current. Theoretically, either method is equally good, but, as will be shown later on, there are some practical reasons which generally make in favour of the second or parallel arrangement of machines. Before entering upon a detailed explanation of either method it will be useful to anticipate and answer a question which naturally presents itself in connection with this subject. The question is the following: Why should we go to the trouble of running three machines if we want to know only the efficiency of one; and would it not be equally good to determine the efficiency of this one machine by running it idle as a motor and measuring the power required to drive itself? This would, in fact, correspond to the usual practice with steam engines of taking so-called "light running" or "friction" diagrams. The indicated power required by the engine to drive itself is thus determined, and the brake power may be computed in a rough and ready way by subtracting from the full indicated power that which was indicated when running light. The ratio of brake horse-power to indicated horse-power is then the efficiency of the engine. Why should we not do something similar with dynamos? Say we have a machine designed to give an output of 100 kilowatts. Leaving aside for a moment the power required for field excitations, which can be easily measured when the machine is in regular work, we wish to determine the efficiency of the armature as an implement for converting mechanical into electrical power. We run the machine light as a motor, and adjust the field strength so as to get the normal speed. The power required to drive the armature can now be exactly computed from the readings of an ampere-meter and a voltmeter. Say we find eight kilowatts is required. Following the analogue of the steam engine, we would conclude that, apart from the loss through armature resistance, $100 + 8 = 108$ kilowatts must be mechanically supplied to the shaft of this machine if 100 kilowatts are to be taken off at the brushes. If we further find that the field requires three kilowatts for excitation, and that two kilowatts are lost in armature resistance (both of which losses can be accurately measured), we would compute the total efficiency of this machine at $100/(108+3+2) = 88\frac{1}{2}$ per cent.

Whether this computation is correct or not depends entirely on the question whether we are justified in assuming that the waste of power (other than that caused by armature resistance) is the same at all loads; in other words, whether our eight kilowatts required for light running means a constant addition for any load. Theory and experiment both show that this is not so, but that the power lost increases with the load. The reasons for this increase are not far to seek. Consider what are the causes of this loss. Firstly, we have mechanical friction and air resistance; secondly, magnetic friction, or hysteresis; and, thirdly, eddy currents. The air resistance is unimportant and does not depend on the load; the mechanical friction, although it may be expected to increase with the load, is in itself so small that even if it were to increase by 20 or 30 per cent. at full load it would not materially affect the efficiency. As regards hysteresis the case is different. Generally speaking, the loss of power caused by it is of importance, and it is conceivable that this loss may increase with the load, not only by reason of an increase in the strength of the field, but also owing to distortion of the field. Both of these causes affect also the eddy currents, so that we may certainly expect the loss caused by them to increase with the load. Eddy currents occur in the core and in the armature bars only when the intensity of the field changes—that is, under or near the edges of the pole-pieces. When the machine is running light the strength of the field at the leaving edge of the pole-piece is practically the same as that at the entering edge, and, in fact, the same over the whole extent of polar surface, but when a considerable current flows through the armature bars the field becomes distorted by cross-induction. It becomes weakened at the entering edge and strengthened at the leaving edge, so that every bar whilst travelling from one edge to the other is passing through a gradually increasing field. In addition to the eddy currents produced at entry and exit only, as is the case when the machine is working light, there are now also eddy currents produced at the intermediate points. The eddy currents at the entering edge have decreased because there the field has been weakened, but those at the leaving edge have increased because there the field has been strengthened; and since the loss of power through eddy currents may be roughly said to be proportional to the square of the field strength, the gain in one place will not suffice to make up for the increased loss in the other, so that, on the whole, we may expect to find the loss by eddy currents increase with the cross-induction—that is, with the load on the machine. What has here been explained applies equally to drum and cylinder armatures, but in the latter there is another source of loss, absent from the former—namely, the influence of the internal winding. The current passing throug the internal wires of a Gramme armature produces a field the lines of which are more or less parallel to the diameter of commutation. This field is stationary in space, and its lines are therefore continuously being cut by the spindle, hub, arms, and other metal parts within the armature core. The larger the current passing through the armature, the stronger is this field, and the stronger are the eddy currents produced in these metal parts. The power thus wasted must therefore increase with the load. These theoretical considerations are completely verified by experiment, but to make such experiments it is, of course, necessary to determine the losses through eddy currents and mechanical and magnetic friction separately. Various methods exist for making this determination. According to one of them the field of the machine is separately excited, and the armature is supplied with current at various E.M.F.'s. It will therefore run at various speeds. If we plot speeds on the horizontal and currents on the vertical, we find that all the points lie on a straight line, and prolonging this line backwards we obtain by its intersections with the axis of ordinates that current which will just suffice to keep the armature moving imperceptibly. Call this C_o, the current corresponding to speed, *o*. Let C and E be current and E.M.F. at the normal speed, *n*, then the total power wasted in running the armature light is $W = C\,E$, and this consists of two parts—namely, the power wasted in friction and hysteresis, which

is $W_h = W \dfrac{C_o}{C}$,

and that wasted in eddy currents,

$$\text{which is } W_f = W \frac{C - C_o}{C}.$$

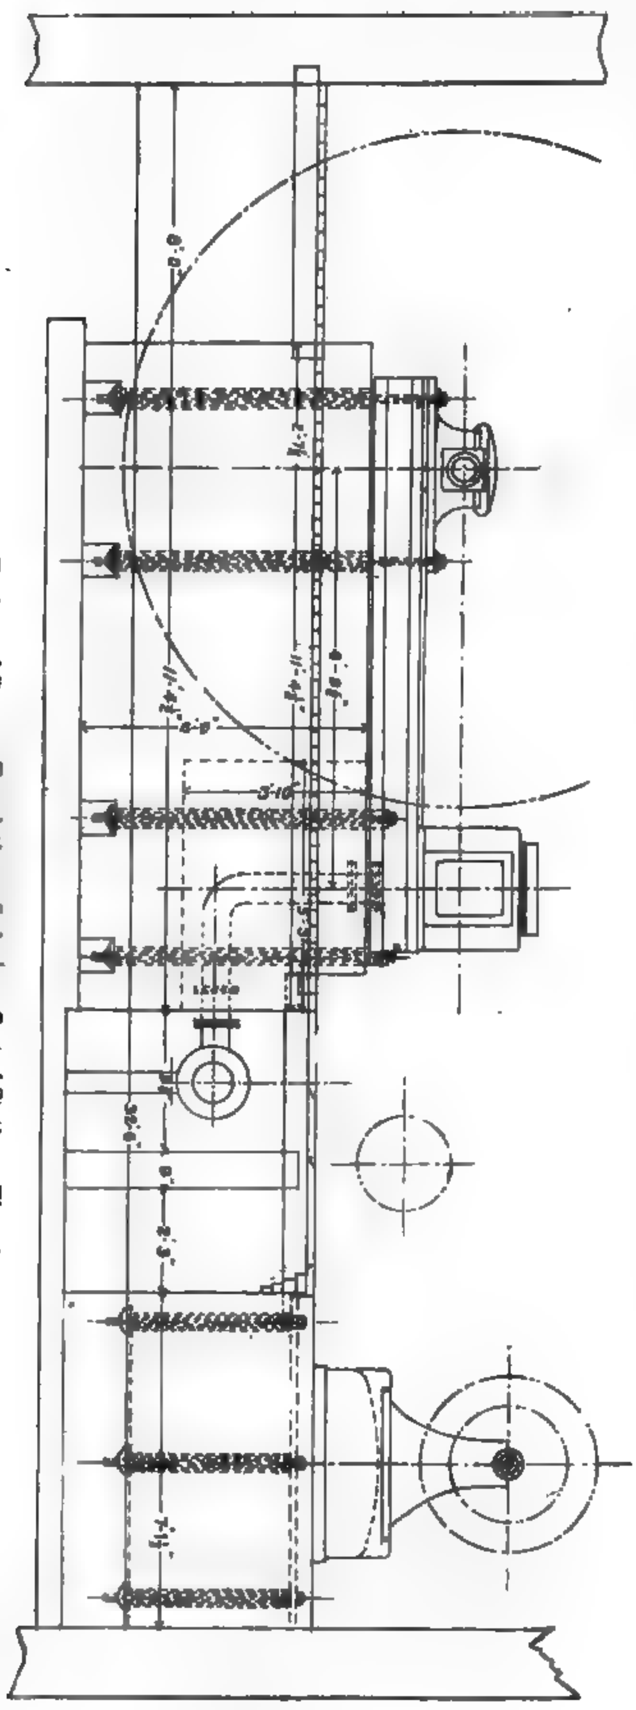
We neglect, of course, the power lost in armature resistance, which, with a machine running light, is insignificant.

Now, imagine two machines of the same type mechanically coupled and electrically so connected that one acts as motor and the other as generator. We supply current to keep the system in motion, and adjust the E.M.F. so as to get different speeds. By making the proper allowance for armature resistance, we can, from the observed values of speed, armature current, supply current, and E.M.F., separately calculate the power lost in eddy currents and hysteresis. It is not necessary to enter into the theory of such tests here; suffice it to say that the value for W_f thus found is always greater than the W_f determined when running light, and that with W_h this is generally also the case.

(To be continued.)

SYDENHAM ELECTRIC LIGHT STATION.

Continuing the account of this installation, designed and constructed for the Installation Company by Messrs. J. E. H. Gordon and Co., we give on this and two following pages illustrations of the details of the engine and dynamo



Engine and Dynamo Foundations—Sydenham Central Station. Elevation.

foundations, which sufficiently explain themselves without description on our part.

ELECTRIC LIGHT SUPPLY.

At the third ordinary meeting of the Dundee Institute of Architecture, Science, and Art, on 14th inst., Mr. C. Ritchie, of the Electric Construction Corporation, delivered a lecture on "Electric Light Supply." Mr. William Mackison, C.E., presided.

Mr. Ritchie began by remarking that but a comparatively few number of persons knew anything about the practical questions of generating electric current on a commercial scale until about 15 years ago, and stating that gas companies had been spurred on to provide better light since becoming aware of the advantages of electricity. Mr. Ritchie afterwards said that the question of the distribution of electric energy had always been a difficult one, but the alternating-current system had survived to the present day. The systems employed for the distribution of electric current over large areas might be divided into two classes—low-tension and high-tension. The low-tension systems of distribution were in practice always applied by continuous current. The simplest form was that wherein two copper conductors were carried through the streets of the area of supply, one being the lead, or positive, and the other the return, or negative. The advantages of this system were its simplicity and the adaptability of the current to the use of motors and accumulators, but its great disadvantage was the enormous cost of the copper required to cover any ordinary area of public supply. To overcome this objection there was in use the three-wire system, the third wire being for the purpose of balancing. While a great saving was effected under this system, it was not sufficient to meet the necessities of an area of supply when the lamps were widely distributed. The high-tension system might be either alternating or continuous, but as the pressure in the houses could not practically be more than 100 volts on account of the lamps, a transformer of some sort must intervene between the high pressure of the generating station and the low pressure of the houses. The most generally adopted system for the utilisation of high pressure was by means of alternating current, the pressure of the generating station being limited by the consideration of the insulation of the wires of the machines and transformers and of the conductors. This system was very simple in its elements, but it had several serious disadvantages, and there were heavy losses under it. Two methods of utilising the high pressure at the generating station were in use, the one by the employment of accumulators, and the other of motor-generators either alone or with accumulators. The advantages obtained from the accumulators were that the generating station need only be running for a comparatively short time each day, and might be shut down for lengthy periods during the summer months, when little current was being consumed. In order, however, to meet with the difficulty of the large expenditure necessary for the accumulators, the motor-generator system had been developed. Mr. Ritchie afterwards explained the working of this system in detail, remarking that as the demand increased the transformers in the sub-stations were put on the one after the other, and as the demand decreased an inverse operation was required to put the transformers out of circuit. By a comparatively small outlay it was a simple matter to adapt this system to any existing low-tension circuit or network of mains without dispensing with the present machinery and mains. It was necessary, he proceeded, to treat high-pressure mains in a different manner from low-pressure mains, just in the same way as with meter pipes. The lecturer afterwards explained the Callender-Webber system of bitumen, remarking that it consisted of a number of conduits formed by bituminous concrete, which were usually about 6ft. long, and said that in this system, as in the preceding, service-boxes were put in at certain intervals for drawing in the necessary cables. Another distinct system of high-tension mains was that in which the lead and return were concentric one with the other, two special forms of these being the Ferranti and the Siemens, under which a special form of service-box was used for joining up. The lecturer concluded by referring to the sites for installations, and to the designing and building of machinery.

LONDON CHAMBER OF COMMERCE.

OVERHEAD WIRES—FRENCH CUSTOMS TARIFF—PALACE EXHIBITION.

The following communications emanating from the London Chamber of Commerce are interesting to electrical engineers.

"County Council By-laws on Overhead Wires.

"Dear Sir,—I beg to send you herewith copy of a letter which was recently sent to the County Council by this Chamber on the subject of the by-laws issued by that body in regard to overhead wires and also a copy of the reply. This letter was written on the representations of one or two of the members of the section that it was impossible to carry on their business if the regulations in question were strictly enforced. I would therefore be glad if you

would carefully peruse the correspondence and forward me any representations you may have to make on the subject, and especially as to whether you consider it necessary to hold a meeting to consider the matter.—Yours faithfully,

"KENRIC B. MURRAY, Secretary.

"January 15th, 1892."

"BY-LAWS—OVERHEAD WIRES.

"Sir,—The attention of this Chamber has been recently directed by several of its members to certain by-laws made by the London County Council in pursuance of the London Overhead Wires Act of 1891, and we are informed that your Council, before instituting these by-laws, made enquiries at several of the leading electrical firms, and that no objection was offered to working under these regulations. We are informed, however, that many, if not all of the firms consulted, are not directly affected by these by-laws, and that another and equally important section of the electrical industry were not consulted, and they, as members of the Electrical Trade Section of this Chamber, propose that a meeting should be held for the purpose of making representations on the subject. My Council, however, recognising the courtesy which we have experienced from you in other matters, as well as in endeavouring to ascertain

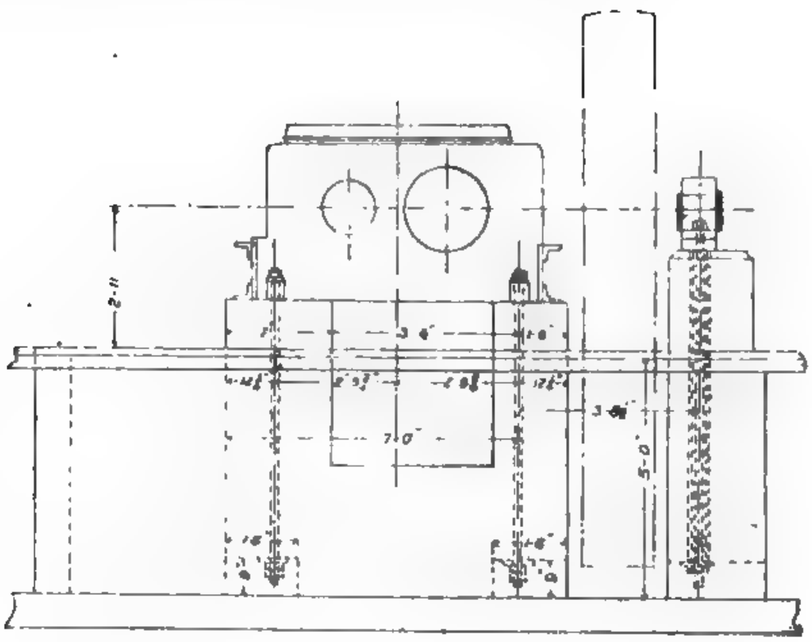
the views of many of the leading firms whom it may have been supposed were principally concerned, direct me, in the meantime, to ask you to be good enough to let us know how the matter now stands.

"I am directed at the same time to suggest that it might be well if you could forward for our information a short statement setting forth the reasons which have induced your Council to enforce these by-laws.—I am, Sir, yours faithfully, KENRIC B. MURRAY, Secretary."

FRENCH CUSTOMS TARIFF.

"To the members of the Electrical Trade Section :

"The following extracts from the new French Customs tariff as definitely passed, to come into operation on the 1st February, 1892, show the duties applicable on the articles mentioned, under the general and minimum tariff. It is understood that the latter tariff will apply to British goods :



Engine and Dynamo Foundations—Sydenham Central Station. Elevation.

"London County Council, 8th January, 1892.

"Sir,—I have to acknowledge the receipt of your letter of the 7th inst. on the subject of the by-laws made by the Council for the regulation of overhead wires.

"The information which you say has been given to the Chamber of Commerce is not quite accurate. The Council did not before making the by-laws make enquiries of the leading electrical firms and ascertain that there was no objection to working under the proposed regulations. The by-laws were made by the Council after careful consideration and consultation with its professional advisers as to what regulations appeared to be necessary for securing the public from accidents which might arise from overhead wires.

"Having made the by-laws, the Council submitted them to the Board of Trade as required by the statute, and at the request of the Board they were advertised at length in the *Times* newspaper, and a copy of them was sent to every company or person in London who appeared likely to be affected by the by-laws. If there are any persons directly concerned who have not received them it has been through want of knowledge, but inasmuch as they were, as I have stated, advertised at length in the *Times*, it was open to everyone to see them.

"The present position of the matter is this: That the Council, before making a formal application to the Board of Trade for confirmation of the by-laws, is prepared, as also is the Board of Trade, to consider any objections or observations which may be offered with regard to them by any persons interested. If, therefore, the members of your Chamber have any representations to make, they should be sent to the Council and the Board of Trade some time before the end of the month.

"With reference to your suggestion that a short statement should be sent to you of the reasons which have led the Council to make these by-laws, the best thing I can do is to refer you to the report of the Select Committee of the House of Commons on the subject in 1885, where legislation was recommended. It is upon this report that the action of the Council has been based.—I am, Sir, your obedient servant,

"H. DE LA HOOKE, clerk of the Council.

"The Secretary of the London Chamber of Commerce."

Tariff No.	Articles.	General tariff per 100 kilos. francs.	Minimum tariff per 100 kilos. francs.
361	Lampes électriques à incandescence munies de leur monture	400	350

"CRYSTAL PALACE EXHIBITION AND RAILWAY RATES.

"Dear Sir,—This Chamber recently approached the London Brighton, and South Coast and the London, Chatham, and Dover Railway Companies with a view of securing a reduced rate on exhibits intended for the Electrical Exhibition at the Crystal Palace. The companies did not see their way, however, to grant reduced rates ; but I am now in receipt of two letters, copies of which I enclose, from which you will see that the companies have agreed to convey the unsold exhibits, on the return journey, free of charge to any station on either of these lines of railway, provided that the exhibits remain the property of the exhibitors.—Yours faithfully, KENRIC B. MURRAY, Secretary.

"January 13th, 1892."

"ELECTRICAL EXHIBITION AT CRYSTAL PALACE, 1892.

"Dear Sir,—Adverting to my letter to you of the 28th ulto., I have the pleasure to inform you that, although we do

not see our way to meet your wishes with regard to making a reduction in the rail-charge for the conveyance of the exhibits to the Crystal Palace, we shall nevertheless be willing to assist the exhibitors in this respect by conveying the unsold exhibits on the return journey from the Crystal Palace back to the station whence they were sent free of charge at owners' risk.

"This concession relates, of course, to traffic from and to our own stations only, and does not in any way affect or disturb the terms and arrangements concerning traffic to places on other companies' lines.

"I should be glad if you would be good enough to notify your Council accordingly.—I am, dear Sir, yours faithfully,

"N. SARLE, Secretary and General Manager."

"London, Chatham, and Dover Railway Company,
"Manager's Office, Victoria Station,
"9th January, 1892.

"Dear Sir,—In reply to your letter of the 15th ulto., I have the pleasure to inform you that, after due consideration, it has been arranged by this company and by the L. B. and S. C. Company for exhibits which were originally sent from stations on our respective systems to be conveyed on the return journey free of charge at owners' risk, providing they remain the property of the exhibitors.—I am, dear Sir, yours truly,

"JOHN S. BATES."

MODERN APPLICATIONS OF ELECTRICITY TO METALLURGY.*

BY G. C. V. HOLMES, SEC.I.N.A.

During the last few years the application of electricity to lighting and to motive power has received the greatest attention from the engineering profession, but comparatively little notice has been taken of the equally important application of this force to metallurgy and the manufacture of metal goods. At the present moment, however, the manufacture of copper goods by electrical methods is beginning to excite considerable attention in the engineering world because of the extraordinary facility with which such articles as sheets, tubes, rollers, wire and tape for electric lighting and telegraphic purposes, etc., can be produced in one operation and of qualities hitherto unattainable. The author hopes, therefore, that a paper on this subject will prove of interest to the society, and as it will probably be considered more satisfactory, instead of giving a mere description of the methods and apparatus actually used in producing the results which have been attained, he proposes to commence by referring briefly to the electro-chemical principles of the subject, then to go on to show how these principles have been applied to that large and important industry—the electric refining of copper—and finally give an account of the methods by which, during the process of the refining of the copper, finished goods, such as those above enumerated, can be automatically produced of absolutely pure metal.

Electro-Chemical Principles.—It was discovered in the first year of the present century that water could be decomposed into its chemical constituents by passing through it an electrical current of sufficient tension. The process is known as electrolysis; the ends of the conductors are called electrodes, that by which the current enters the waters is called the anode, and the end of the other conductor by which the current passes out again is called the cathode. At the surface of the anode, oxygen gas is separated from the water, while at the surface of the cathode hydrogen is formed, each gas being separated exactly in the proportions required to form water. The atoms which are decomposed, or electrolysed, are called in electro-technical language, ions; those which appear at the anode and cathode being named respectively, anions and kathions.

There are three principal laws which express the quantity of action which takes place during the electrolytic process. These laws are of the utmost practical importance to enable the cost of the operation to be ascertained. They are as follows:

I.—The amount of chemical action is equal at all points of a circuit. For instance, if the current were passed through a series of vessels, connected by a series of conductors, the ends of each of which were immersed in the water of two adjacent vessels, the first and last conductors being connected respectively with the positive and negative poles of the source of electricity, so that the whole formed one continuous circuit, then the amount of water decomposed in each vessel in the circuit would be equal.

II.—The amount of the chemical action which takes place in a given time is exactly proportional to the quantity of the current which passes through the vessel. For instance, a current of six amperes would decompose three times the quantity of water in each vessel which a current of two amperes would separate in the same time.

III.—The amount of hydrogen liberated by the passage of a current of one ampere through water during one second is ·000015 gramme. This quantity is called the electro-chemical equivalent of hydrogen. The amount of any other chemical element liberated at an electrode by the passage of a current of electricity of one ampere during one second through any other solution, containing the chemical element in a form in which it can be electrolysed, is exactly equal to the electro-chemical equivalent of hydrogen multiplied by the chemical equivalent of the element in question. Thus the chemical equivalent of oxygen is 8, and the weight of oxygen liberated by the above-mentioned current in a vessel of water would be $\cdot0000105 \times 8 \doteq \cdot0000840$, which number is therefore its electro-chemical equivalent. Below is given a table of the atomic weights and electro-chemical equivalents of the principal elements which have to be considered in electrolytic work.

TABLE I.

Name of element.	Atomic weight.	Chemical equivalent.	Electro-chemical equivalent in grammes per ampere-second.
Hydrogen	1·0	1·0	·0000105
Potassium	39·1	39·1	·0004105
Sodium	23·0	23·0	·0002415
Gold	196·6	65·5	·0006875
Silver	108·0	108·0	·0011340
Copper	63·0	31·5	·0003307
Mercury	200·0	100·0	·0010500
Tin	118·0	29·5	·0003097
Iron	56·0	14·0	·0001470
Nickel	59·0	29·5	·0003097
Zinc	65·0	32·5	·0003412
Lead	207·0	103·5	·0010867
Oxygen	16·0	8·0	·0000840
Chlorine	35.50	35·5	·0003727
Nitrogen	14 00	4·3	·0000490

Nothing has yet been said regarding the energy required to effect the decomposition. Taking, again, the case of water. . As soon as the smallest quantities of oxygen and hydrogen appear at the anode and cathode respectively, the apparatus is converted into a secondary battery, the elements of which—viz., the two above-named gases—tend to combine, and in so doing develope an E.M.F. of 1·45 volts. The current employed to effect the decomposition must therefore possess at least an equal E.M.F., and in addition whatever E.M.F. is necessary in order to overcome the electrical resistance of the generator of electricity, the conductors, and the liquid between the anode and cathode.

If Q be the quantity of electricity passing through the circuit, E the back E.M.F., E^1 the E.M.F. necessary to convey the current through the above-named resistances, then the work done by the current $= Q\,(E + E^1)$.

The E.M.F. of any particular chemical reaction is equal to the product of the electro-chemical equivalent of the separated ion into its heat of combination when entering into the combination in question expressed in dynamical units. For explanation of this reference is made to the work on "Electricity and Magnetism," written by our distinguished past-president, Prof. Silvanus Thompson, F.R.S.

The above law is expressed as a formula as follows: Let E be the E.M.F. in volts; Z, the electro-chemical equivalent of the separated ion; H, the number of units of heat evolved by a gramme of the substance when entering into the combination; and J, Joule's equivalent (42×10^6), then $E = Z\,H\,J$.

Taking as an illustration the case of copper dissolving into sulphuric acid, from the above table $Z = \cdot003307$, $H = 881$, $J = 42 \times 10^8$, then $E = \cdot003307 \times 881 \times 42 \times 10^8 = 1{\cdot}223 \times 10^8$ "absolute" units of E.M.F. = 1·223 volts.

To consider next the case of the electrolysis of sulphate of copper solution with an insoluble anode such as platinum. The chemical expression of this combination of copper, sulphur, and oxygen is $CuSO_4$, which differs from sulphuric acid (H_2SO_4) in that the two atoms of hydrogen are replaced by one atom of copper.

When the current of sufficient E.M.F. is passed through a solution of this salt in water the $CuSO_4$ is split up into Cu, or metallic copper, which is deposited on the cathode, and SO_4, which decomposes the water of the solution, forming sulphuric acid and free oxygen.

Thus:
$$CuSO_4 = Cu + SO_4$$
$$SO_4 + H_2O = H_2SO_4 + O.$$

The result is in the end the same if it is supposed that the current in the first instance decomposes the water of the solution. In this case, as before, oxygen appears at the anode and hydrogen at the cathode. The free hydrogen, however, at once decomposes the sulphate of copper, replacing the copper, which latter is deposited in the metallic form on the cathode. If the current is passed for a sufficiently long time through the solu-

* Paper read before the Junior Engineering Society, Jan. 15.

tion, the whole of the copper will be extracted from the salt and will be deposited, and the solution itself will be converted into dilute sulphuric acid. The minimum work done in effecting the decomposition expressed in watts is equal to the current expressed in amperes multiplied by the back E.M.F. in volts of copper entering into combination with sulphuric acid. This E.M.F. has been shown above to be 1·223 volts, and if Q amperes be the quantity of electricity passing per minute, then $Q \times 1{\cdot}223$ watts per minute is the minimum energy required to effect the decomposition, to which has to be added the energy required to overcome the resistances of the generator of electricity, the conductors, and the electrolyte.

The author lays stress upon these elementary facts in order to pave the way, in a systematic manner, to ascertaining the commercial cost of refining rough copper.

Coming next to the case of electrolysing the same sulphate of copper solution, but employing an anode of pure copper instead of the insoluble anode of platinum taken in the last instance. In this case we may suppose, as before, that copper is deposited on the cathode and oxygen liberated at the anode, while part of the solution is turned into sulphuric acid. The nascent oxygen, however, combines with the copper of the anode, forming oxide of copper, which latter immediately dissolves into the sulphuric acid present, re-forming sulphate of copper and liberating an equivalent amount of water. Thus, everything is restored to its first condition, and the process goes on continuously; copper being deposited from the solution on to the cathode, while it is dissolved in precisely equal quantities from the anode, and the solution, instead of being converted into dilute sulphuric acid, as in the first case, is constantly replenished with copper, and is maintained as a solution of the sulphate of that metal, and serves, in fact, as the medium for transmitting the metal of the anode to the cathode. Thus we see that whatever chemical changes occur at one part of the combination precisely opposite changes occur at another part, and consequently no work whatever is done in the purely chemical part of the operation; and if the solution, the conductors, and the electric generator had no resistance—that is, were of perfect conductivity—then an electric current of infinitely small E.M.F. would effect the deposition. The same facts may be put in another way by stating that there is no back E.M.F. in the bath, because the nascent oxygen liberated at the anode, instead of tending to combine with the deposited copper on the opposite cathode—thus forming an electric couple—combines at once with the copper of the anode with which it is in contact, while the energy of the combination is balanced by the simultaneous absorption of energy due to the decomposition of the metal at the cathode.

This elementary fact, which is perfectly well known to those who have conducted the simplest experiment in copper plating, is the sole secret of the extraordinary cheapness of the process of the electro-refining of copper. In practice, of course, the generator, the conductors, the electrodes, and the solution offer a definite, even if very small, resistance to the passage of the current, and the current must have a corresponding E.M.F. in order to overcome these resistances, but it must be definitely understood that in electroplating copper from a pure copper anode the overcoming of this imperfect conductivity is the sole work done by the current, the energy employed in doing chemical work being nil.

It may here be mentioned that in order to promote free action, and in order to improve the conductivity of the electrolyte, a certain amount of free sulphuric acid is always put into the bath along with the water and the copper salt, and consequently, if there is a considerable inequality between the areas of anode and cathode, more or less copper may be dissolved into the solution than is deposited on the anode, according to which area predominates, and consequently the liquid may vary in richness of salt during the time the current is passing.

The case of depositing the metal from an impure copper anode introduces at once the metallurgical industry of refining raw copper. The rough copper of commerce is usually alloyed or mixed with various other metals, and there is no immediate apparent reason why they should not be dissolved by the action of the current into the free sulphuric acid present in the solution in the bath and deposited together with the copper on the cathode. It will be presently seen, however, that with ordinary precautions such action does not take place, but that the copper is deposited in a pure state.

When an anode is composed of a mixture or an alloy of several metals, and the electric current passed through, the various component metals are not oxidised and dissolved simultaneously. They are, on the contrary, attacked in a certain order depending upon the energy which they develop when combining with oxygen and dissolving into the acid of the solution. The metal which is attacked first is that which by its oxidation developes the greatest energy, or which, if used as one of the elements of a primary battery, would develop the highest E.M.F.; and so on in regular order. *Vice versâ.* When several metals are simultaneously in solution in the bath the order of deposition is the reverse of the order of dissolution—that is to say, that metal will be first deposited the separation of which from the solution requires the least amount of energy. This law, the author believes, was first stated by Dr. Kiliani, of Munich, and was published in the German "Bergen Hütten Münnische Zeitung" in the year 1885.

The subject-matter of this law is a very large one, and whether its application to all the metals found in combination with rough copper has been fully studied is a matter of very much doubt. Concerning a few of the metals, such as silver, lead, iron, copper, and zinc, however, when dissolved into and deposited from a few electrolytes, pretty extensive researches have been made. The following are some of the principal metals found in combination with copper: Manganese, zinc, iron, tin, cadmium, cobalt, nickel, lead, arsenic, bismuth, antimony, copper, silver, gold. They are given in the order of the heats of combination developed by them when undergoing oxidation. The list therefore also gives the order in which they would be dissolved according to Dr. Kiliani's law; while if in solution they would be deposited in the inverse order.

It will be noted that copper comes almost at the bottom of the list, having only the precious metals silver and gold below it. It is largely to this circumstance that is due the facility with which copper can be refined, for under the ordinary circumstance of deposition neither the gold nor the silver oxidise and dissolve into the electrolyte at all, but fall to the bottom of the bath in the shape of metallic powder when the surrounding metals in which they are embedded dissolve away; hence the copper is left as the metal most easily separated from the solution, and in accordance with the law previously stated it is deposited on the cathode before any of the other metals, all of which are oxidised and some dissolved into the solution before it. It must, however, be acknowledged that the above statements are only true and the law applicable so long as certain conditions relating to the strength and E.M.F. of the current, the composition of the electrolyte, and the proportion of the foreign metals in the anode are observed.

As an instance of some of the variations that occur, it may be stated that if the E.M.F. of the current exceed a certain degree several of the metals may be dissolved and deposited simultaneously. This peculiarity is obviously due to the fact that, when they dissolve into the solution, each metal can be electrolysed by a current having an E.M.F. somewhat higher than the natural E.M.F. due to the combination of the metal with the acid of the bath. (See the case of the electrolysis of sulphate of copper between insoluble anodes.) If, then, the electrolyte contained several metals in solution and the E.M.F. of the current were gradually increased, each of them would, in turn, be separated from the solution and deposited. If, on the other hand, the E.M.F. at the outset were higher than the highest natural E.M.F. which could be developed by any metal present entering into the combination in question, then all of them would simultaneously be separated and deposited. If the current density per unit of area of cathode exceed a certain amount (approximately five amperes per square foot of surface) the copper will not be deposited in the metallic form at all, but will fall to the bottom of the bath in the shape of powder. The composition of the electrolyte—*i.e.*, the proportions of free acid, copper sulphate, and water—exercises an important influence on the character of the deposit, as also does the temperature. The more neutral and the poorer in dissolved copper the electrolyte, the more easily will the metals low down in the above list be dissolved, and the more easily also will those high up in it be deposited. The precise reasons for some of the above peculiarities have never been exactly ascertained, and hence it comes that the practice of the electrolytic refining of copper, though reposing in the main on well-ascertained scientific principles, involves the knowledge and use of so many expedients and precautions that it is by no means the easy and straightforward work which might be supposed.

In addition to the metals themselves, the oxides and sulphides of some of them may be present in the anodes, and some oxides which cause difficulties are formed by the action of the current. Those, for instance, of lead and tin are insoluble in sulphuric acid. Others dissolve but slowly, and while they remain on the surface of the anodes they will act precisely as the lead peroxide does in a secondary battery—that is to say, they will form with the copper on the cathode a more or less powerful electric couple, the E.M.F. of which acts in the opposite direction to that of the current. Hence, the current must in such circumstances have an E.M.F. sufficient to overcome this back force, in addition to being able to overcome the resistances of the generator, conductors, and electrolyte, and the cost of the deposition will be proportionately increased. In practice, however, with anode of the degree of purity generally used for electrofining this back E.M.F. is not considerable, as the whole E.M.F. required to overcome all the conductive resistances and the back force varies according to the current density used, between a quarter and half a volt per tank. It should, however, be mentioned that the oxides being relatively non-conductors, if the position of the anode in the bath be such that they accumulate on the surface of the latter and cannot escape, the conductive resistance may be considerably increased. This is a point of considerable importance for two reasons: first, the

increase in the resistance increases the cost of the electric current; and, second, owing to the increased E.M.F. necessary to move a given current through the circuit, the deposition of the other metals which may have been dissolved into the electrolyte is facilitated and the refining action of the current correspondingly diminished.

Copper-refining Apparatus.—The practical apparatus required to refine rough copper electrolytically is of the simplest kind. A boiler, steam engine, and dynamo are of course indispensable. What the electrical output of the latter shall be is of course determined by the surface of anodes which it is intended to expose in any one tank or bath, the usual allowance being a current of between four and five amperes per square foot of surface. The E.M.F. of the current depends upon the number of tanks which it is intended to work in series—*i.e.*, through which it is intended to drive the current—and also on the average of the combined resistances per tank. With a well-arranged plant the difference of potential between the anode and the cathode of each tank should be considerably less than half a volt. The tanks are generally made of wood and measure about 3ft. in each direction. They are rendered acid-proof by being lined with lead, or some composition into which pitch enters largely. It is of the utmost importance that the tanks should be perfectly acid-proof, not only in order to avoid loss of the electrolyte by leakage, but also to ensure the electrical insulation; for the sulphate of copper solution, containing as it does free sulphuric acid, is a very good conductor, and if the floors in the neighbourhood of the tanks got to be saturated with it a considerable proportion of the current would be lost to earth. On the tops of the sides of the tanks at front and back are placed strips of copper, which serve as conductors, and which are alternately connected. The anodes are square plates of cast rough copper, the tops of which are in contact with rods of the same metal, which rest on the two conductors, that end which rests on the conductor which conveys the current to the next tank being, of course, insulated. The cathodes are sheets of thin copper similarly resting on the conductors, only in this case the ends reposing on the other conductors are insulated. Several anodes and cathodes are hung parallel to each other in each tank, and when a sufficient thickness of electrolytic copper is deposited on the cathodes they are removed from the bath and the deposited layer is easily split away from the original cathode, which remains intact and ready for fresh use. The thickness of the deposited copper on the cathode is a matter principally affected by the capital at the disposal of the firm for locking up in raw material. The electrolyte is formed by dissolving 2lb. of sulphate of copper to each gallon of water and adding 8oz. of concentrated sulphuric acid. The aim of the refiner is to procure a supply of rough copper containing a good proportion of gold and silver. Many brands of copper are exceedingly rich in the precious metals, and it is usual to allow a certain proportion of the assay value free to customers.

Cost of the Process.—The cost of the operation of refining copper is determined mainly by the difference of potential between the anodes and cathodes in each tank. The lower the latter, of course the less cost. It has been shown that with a pure anode only sufficient E.M.F. has to be provided to overcome the ordinary resistances, while with an impure anode an additional difference in potential is required to overcome the back E.M.F. due to the accumulation of oxides on the anode, and a portion of the energy of the current is of course absorbed in oxidising the foreign metals present. It so happens that while it is easy by the old methods to refine rough copper up to, say, 98 per cent., it is very difficult by these methods to get it still purer. By the electrolytic methods, on the contrary, it is much easier to take the last impurities out than it is to refine a really rough copper. Thus, the two methods may be said to be complimentary to each other, and in practice it is desirable to bring the metals by the older methods up to such a state that only about 2 to 3 per cent. of impurities remain in it. The principal resistance to conductivity is in the electrolyte itself. This resistance can be diminished by reducing the length of liquid which the current has to traverse and by increasing its cross-section—that is to say, by bringing anode and cathode as close together as is found to be practicable and by exposing as large an area as possible.

(To be continued.)

COMPANIES' REPORTS.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY.

Directors: Eustace J. A. Balfour, Esq. (chairman), H. Woodburn Kirby, Esq. (vice-chairman), Latimer Clark, Esq., F.R.S., Egerton H. Clarke, Esq., Sir John H Morris, K.C.S.I., Charles Showell, Esq. General manager and secretary: Frederic J. Walker. Chief engineer: S. T. Dobson, A.M.I.C.E., M.I.E.E.

Report of the Directors and statement of accounts for the year ending 31st December, 1891, to be presented to the shareholders at the ordinary general meeting to be held at the St. James's Hall Restaurant on Tuesday next, at 3 p.m.

The Directors in submitting their annual report for 1891, with accounts as certified by the Company's auditors, congratulate the shareholders on the satisfactory progress made by the Company during the past year. Early in 1891 the capital of the Company was increased from £100,000 to £200,000 by special resolution of the shareholders, creating 20,000 7 per cent. preference shares of £5 each. Of these shares 10,000 were issued to the shareholders at par, and fully subscribed for by them in March. The balance of 10,000 shares was issued in December last at 30s. per share premium, and duly allotted to the shareholders. This last issue of shares placed £15,000 at the disposal of the Directors as a capital reserve fund. The £15,000 has since been invested in 2¾ per cent. annuities, and is shown in the accounts annexed hereto. The attention of the Directors has been largely directed during the year to the purchase of land for, and the erection of, a northern station. Owing to the congested condition of the parish and the extreme scarcity of available ground this proved to be a difficult matter. The Directors, however, are pleased to be able to report that they have secured a suitable freehold site in Carnaby-street, Regent-street, and have entered into a contract for the erection of the building on designs prepared by Mr. C. Stanley Peach, F.R.I.B.A. A considerable portion of the machinery and boilers required for this station have also been constructed, and it is hoped that during the summer of this year the station will be finished and in working order. There are certain compulsory mains which have to be laid in the parish before August next. These, with other mains which the Board deem necessary to complete the system, will be proceeded with without loss of time, and there seems every reasonable probability of the whole of the work being completed without any further capital being required. It may be of interest to the shareholders to know that the two stations will be connected by a grand trunk main, about half of which is already completed and laid. This will be a means of enabling the northern station to support the southern in case of necessity, and *vice versâ*. The system adopted by the Company has worked thoroughly well during the whole of the year, and the Directors are satisfied that it is the best that could be selected having regard to present knowledge. The experience gained at the Company's works enables the Company's officials to make improvements from time to time, and no precaution is neglected to maintain the excellent results hitherto obtained. The net earnings of the Company during the past year have amounted to £10,395. 12s. 5d. Of this sum £3,610. 6s. 4d. was distributed in July last in payment of an interim dividend at the rate of 7 per cent. per annum for the half-year ending June 30, 1891, on the ordinary shares, and on the instalments paid on the first issue of preference shares. The balance of £6,785. 6s. 1d., added to £315. 12s. 9d. (the undivided profit from last year's account), leaves £7,100. 18s. 10d. now to be dealt with. The Directors propose to divide this amount as follows—viz.:

	£	s.	d.
(A) By payment of a dividend at the rate of 7 per cent. per annum calculated on the instalments paid on the first issue of 10,000 preference shares for the second half of the year	£1,333	6	8
(B) By payment of a dividend at the rate of 10 per cent. per annum for the second half-year on the ordinary shares, making, with the interim dividend paid in July last, a total distribution of 8½ per cent. for the year	4,670	0	0
(C) By paying a dividend of £10. 15s. per share on the founders' shares	1,075	0	0
(D) Amount to be carried forward to ordinary shareholders' undivided profit account	6	2	6
(E) Amount to be carried forward to founders' undivided profit account	16	9	8
	£7,100	18	10

The Directors have carried £1,000 to redemption account to commence a fund, to accumulate by annual additions, to represent loss of capital at the expiration of the term covered by the provisional order. The Directors are advised that the amounts provided in the accounts for depreciation are sufficient and ample for all purposes. Two of the directors—namely, Messrs. Egerton H. Clarke and H. Woodburn Kirby retire under Clause 79 of the articles of association, and, being eligible, offer themselves for re-election. The auditors, Messrs. Deloitte, Dever, Griffiths, and Co., also retire, and, being eligible, offer themselves for re-election.

COMPANIES' MEETINGS.

DIRECT UNITED STATES CABLE COMPANY.

The twenty-ninth ordinary general meeting of this Company was held at Winchester House on Friday, the chairman, Sir John Pender, K.C.M.G., presiding.

Having referred in sympathetic terms to the death of the Duke of Clarence, the **Chairman** said that the revenue for the half-year ended the 31st ult., after deducting the out-payments, had been £45,402, while the working and other expenses, including income tax, but excluding the cost of repairs, had absorbed £17,673, leaving a balance of £27,729 as the net profit of the half-year, which was increased by the amount brought forward to £31,231. Interim dividends of 3s. 6d. a share had been paid for the quarter ended September 30 last, and for the quarter ended the 31st ult., £5,000 had been added to the reserve fund, and a balance of £4,983 had been carried forward. The revenue showed an increase of £2,055 compared with that of the corresponding period of last year. The M'Kinley tariff had no doubt restricted trade in many quarters, and but for the large operations in grain owing to the deficient harvest in Europe, the revenue of the Company would probably have shown a falling off. The reserve fund account had been charged with £4,478 for the cost of repairs of cable, but it had been credited with £4,303 interest on investments, and with £5,000 from the revenue account, increasing the balance of the reserve account to £259,680. There was no doubt that the preparations for next year's great exhibition would benefit their revenue, but until such a growth of telegraphy came as to fully employ all the cables in the Atlantic they did not think they could look forward to any very large increase in their returns. During the past six months they had had to effect one repair in their cables, and in carrying out this work they took up a portion of the cable, which was in such a condition as to satisfy them that although it was 17 years old, it had a considerable number of years of life in it yet. He moved the adoption of the report.

This was seconded by **Mr. Wm. Ford**, and carried unanimously.

NEW COMPANIES REGISTERED.

Metropolitan Light Company, Limited.—Registered by J. Hands, 15, Old Jewry-chambers, with a capital of £5,000 in £1 shares. Object: to acquire the undertaking of D. C. Defries, now carried on at 43 and 44, Holborn-viaduct, under the style of the Metropolitan Light Company, in accordance with an agreement made between D. C. Defries of the one part and this Company of the other part, and generally to carry on business as gas, electrical, and general engineers. There shall not be less than three nor more than five Directors. The first to be appointed by D. C. Defries. Qualification: D. C. Defries, as managing director, £1,000; ordinary Directors, £500.

BUSINESS NOTES.

West India and Panama Telegraph Company.—The receipts for the half-month ended January 15 were £2,331, against £2,791.

St. James's and Pall Mall Company.—The Directors recommend a dividend at the rate of 10 per cent. per annum on the ordinary shares for the half-year ended December 31, 1891.

National Telephone Company.—The Directors have unanimously elected Mr. James Staats Forbes, one of the vice-presidents, as president of the Company, in succession to the late Mr. Frederick Richards Leyland.

City and South London Railway.—The receipts for the week ending 17th inst. were £836, against £765 for the corresponding week of last year, showing an increase of £71. As compared with the week ending Jan. 10th, the receipts show a decrease of £22.

Electric Contractors.—An electrical department has been added to the business of Messrs. H. Turner and Son, ironmongers and cutlers, 28, Villiers-street, Strand, W.C. Messrs. H. Turner and Son announce themselves prepared to submit estimates for electrical work of every description, especially electric lighting and wiring.

Brush Electrical Engineering Company.—The Directors have declared an interim dividend upon both the ordinary and preference shares of the Company at the rate of 6 per cent. per annum for the six months ended 31st December last, payable on the 15th February next. The transfer-books of the Company will be closed from the 20th to the 27th inst.

Laing, Wharton, and Down.—With regard to the recent removal of the offices of the Laing, Wharton, and Down Construction Syndicate, Limited, to 38, Parliament-street, Westminster, this change in no way relates to the old-established firm of Messrs. Laing, Wharton, and Down, whose address remains 82A, New Bond-street, W., with the addition of branch and City offices at 17, Gracechurch-street.

The Anglo-American Telegraph Company recommend a balance dividend of 16s. per cent. on the ordinary consolidated stock for the year ending December 31, and balance dividend of £1. 12s. per cent. upon the preferred stock for the year ending December 31, both payable on January 30, less income tax, to the stockholders registered on the books on the 12th inst. After paying the foregoing dividends there will be a balance of £864 to be carried forward. The above dividends, together with those already paid, will amount to £2. 12s. 6d. per cent. on the ordinary and £5. 5s. per cent. on the preferred stocks for the year 1891.

City of London Electric Lighting Company.—In fulfilment of the pledge given at the statutory meeting, that shareholders should have the first offer of the unissued 9,848 ordinary shares in the Company, the Directors have decided to allot the whole of these *pro rata* to shareholders on the register on January 14th. A circular has therefore been issued by Mr. J. Cecil Bull, secretary, offering shareholders shares at the rate of as nearly as possible one for every three held, at 5s. premium. The first payment of £3. 5s. per share will be due to-morrow (Saturday), and if not paid by then the allotment will be forfeited. After the second payment of £3 per share on February 1st next, the shares now allotted will rank *pari passu* in all respects with existing shares.

NOTES.

Church Lighting.—The electric light has been installed at All Saints' Church, Southampton.

Austria.—An electrical tramway is contemplated in Austria between Mähuish-Oshan and Prziwos.

Crystal Palace.—The visit of the Lord Mayor and Lady Mayoress to the Electrical Exhibition will take place on 6th February.

St. Petersburg.—The electrical exhibition at St. Petersburg was formally opened on Saturday by the Russian Minister of Finance.

Station Burnt.—The central station at Ferdinand-street, Boston, U.S. was burnt to the ground last Saturday, and one man lost his life in the ruins.

Municipal Lighting.—One of the Paris municipal councillors, it is stated, is preparing a work on the electric lighting of towns, with full and interesting figures.

Santa Fe.—The electric light, it is stated, in Santa Fé has proved a failure, and the municipality has returned to kerosene. There must be reasons for this, and it would be well to know these.

National Telephones.—On Wednesday the Examiners on Standing Orders passed the National Telephone Company and New Telephone Company's Bills for obtaining further telephone facilities.

Old Students' Dance.—A Cinderella dance will be held by the Old Students' Association on Friday, February 19, at the Westminster Town Hall. Tickets, 3s. 6d. each, of the Hon. Sec., 28, Lanhill-road, Elgin-avenue, W.

Anglo-French Telephone.—The French Chamber has adopted the convention concluded with Great Britain defining the conditions, working, and use of the telephone communications between the two countries.

Yacht Lighting. — The yacht "Tycho Brahe," belonging to Mr. "Bonne-Chance" Wells—the gentleman who broke the bank at Monte Carlo—has been luxuriously lighted with electric light by Messrs. Laing, Wharton, and Down.

Portsmouth.—At the meeting of the Portsmouth Town Council last week the question of the report from the Electric Lighting Committee was brought forward by the Mayor, but was adjourned until the next monthly meeting.

Electric Exhibition at Moscow.—An electric exhibition is to be held at Moscow, from April 14 to October 14, 1892. It will comprise 12 divisions of electric engineering. New inventions shown will not lose the right to be patented in Russia.

Tenders for Manchester.—As will be seen by their advertisements, the Manchester Gas Committee are now open to receive tenders for the supply of dynamos and for the supply and laying of culverts and electric light mains. These must be sent in by Feb. 23rd.

Brussels.—The result of the tenders for Brussels is not yet announced. The six firms tendering have been invited to furnish graphical diagrams of working. It is expected that a central station to light 10,000 lamps in winter and 5,000 in summer will be first erected.

Spain. — Three additional towns in Spain, states *Industries*, are endeavouring to obtain permission to erect central electric light stations. One is Linares, the lead-producing centre; the next is Baesa, a small town in Andalusia; and, lastly, Alcaniz, in Aragon.

Chicago Exhibition.—The estimates of the electric light to be used in the World's Fair at Chicago show that twice as many electric lights will be used as there are at present in the whole of Chicago. The plans call for 10 times the capacity of all the plant used in the Paris Exhibition.

Society of Arts.—In consequence of the illness of Prof. W. C. Unwin, F.R.S., the Howard lectures on "The Development and Transmission of Power from Central Stations," which he was announced to deliver on the 5th February and five following Friday evenings, has been postponed.

The Brush Company.—Mr. Garcke has resigned the position of managing director of the Brush Electrical Engineering Company, but he retains his seat at the board of directors. Mr. Raworth and Mr. Sellon have been appointed joint managers, and Mr. Geipel has been appointed superintending engineer of the company.

Tutbury.—A movement is on foot to provide Tutbury with the electric light. It appears that motive power exists at the mill occupied by Messrs. Staton, and with little outlay sufficient light could be obtained. A circular has been issued to the parishioners, and the reply to this will determine whether the new light will be adopted.

Mr. Tesla's Lecture.—An extraordinary general meeting of the Institution of Electrical Engineers is to be held, by kind permission of the managers, at the Royal Institution, Albemarle-street, on Wednesday, 3rd February, at 8 p.m., when Mr. Nikola Tesla will give his paper upon "Experiments with Alternate Currents of High Potential and High Frequency."

Electric Boats.—The General Electric Traction Company have recently taken the shipbuilding yard lately occupied by Des Vignes, and are now engaged in building the hulls of their electric launches, which are fitted with gearing at the works at Platt's Island. They have three boats now in hand—one of these, a 25ft. boat, is a second order from a private gentleman for use on the Thames.

The Sea Serpent at Last.—In the Machinery Department of the Electrical Exhibition at the Crystal Palace may be seen a fine specimen of the "Gymnotus electricus," or sea serpent. This animal having swallowed a portion of the shore end of the Atlantic cable of 1859, became transformed into a powerful electrical machine. In the process of grappling for the fault the body was brought to the surface, and will be the subject of some interesting experiments!

Secondary Batteries.—The work upon "Secondary Batteries: being a Description of the Modern Apparatus for the Storage of Electrical Energy," by Mr. J. T. Niblett, illustrated, is now published (Biggs and Co., 3s. 6d.). The work is not a theoretical disquisition on the action of secondary batteries, but rather a careful description of all the recent commercial developments of Planté's discovery, and one which it is hoped will be of great service to electrical engineers.

"Year-Book of Commerce."—We have received the third year's issue of the "Year-Book of Commerce," being a statistical volume of reference for business-men, compiled by Kenric B. Murray, of the London Chamber of Commerce, assisted by members of numerous statistical societies; published by Cassell's; price 5s. For those who have to do with foreign trade, the state of the labour market, agriculture, exports, and so forth, the book must prove one of great value.

Electric Power for the City.—The Streets Committee of the City Commissioners of Sewers reported on Tuesday relative to a communication from the Board of Trade asking for the Commission's opinion on the systems by means of which electrical energy was to be supplied under the City electric lighting orders. They stated that

they ascertained from Mr. W. H. Preece, F.R.S., that no objections could be raised to the proposed modes of distributing electrical energy.

Cantor Lectures.—Prof. Forbes will continue his Cantor lectures at the Society of Arts on Monday, February 1st, at 8 p.m., on "Developments of Electrical Distribution," dealing with high-pressure supply; old attempts; alternate currents; transformers; feeders; sub-stations; overhead and underground conductors; generation of electricity by power obtained from a distance, from electricity, gas, compressed air, and water under pressure; load factors; waste products.

Electricity in Agriculture. — Prof. Warner, of Amherst Agricultural College, Massachusetts, has been making a series of investigations upon the influence of electricity in agriculture. The results of the research will be published. Mr. W. W. Rawson, market gardener, of Arlington, whose experiments we have already mentioned, has found that the use of electric light has increased his profits from the growth and sale of lettuces, etc., by more than 25 per cent.—a practical enough effect.

Telephones in Hotels.—An indication of the extending use of the telephone for private use is shown in the fact that The Adelphi Hotel, Liverpool, has been fitted with a complete interior telephonic installation. Each room on the three principal floors of the building is fitted with a call-box and magnetic transmitter, by means of which visitors may communicate with each other or with the hotel staff at any moment. The work was carried out by Mr. G. A. Nusbaum, of 29, Ludgate-hill, E.C.

Electrical Engineering as a Profession.—The University of Sydney have recognised the claims of electrical engineering by adopting a proposal by Prof. Threlfall at the last meeting of the senate, "that the faculty cordially approves of Prof. Threlfall's proposal for the establishment of a curriculum in electrical engineering, and recommends that it be carried out by the senate, including the suggestion of a grant of £300 for the necessary apparatus." It was also decided that the curriculum should lead up to the degree of Bachelor of Engineering in Electrical Engineering.

Where the Profit Goes.—The London County Council have found that, in order to supervise efficiently the work of installing the electric light in the central offices, it has been found necessary to employ an assistant inspector (Mr. J. J. Thornton) at £2 a week. Inasmuch as the extra assistance has been necessitated by the contractor's request to be allowed to work until 11.30 p.m., they think it would be reasonable to charge half the cost to Messrs. Andrews, the contractors, and have accordingly authorised the employment of the assistant inspector on that understanding.

Telephone Service in Bulgaria.—The new telephone service between Sofia and Philippopolis, a distance of 100 miles, was inaugurated with considerable ceremony on the 24th inst. by Prince Ferdinand in person. All the arrangements, which had been organised with great care by M. Matheff, Director-General of Posts and Telegraphs, were most successfully carried out. Amongst the distinguished personages present were M. Stambuloff (the Premier), M. Grecoff (Minister for Foreign Affairs), several members of the diplomatic body, and a number of civil and military officials of high rank.

Technical Instruction at Darlington. — The Technical Instruction Committee appointed by the Darlington Town Council have, with the grants from the County Council for technical education, made a good beginning by arranging with Principal Garnett, of the College of Science, of Newcastle, for the course of 12 lectures on electrical engineering. The charge for the course is nominal. The first lecture was given at the Kendrew-street Board Schools, and was well attended, the new departure being regarded with great interest by the leaders of education in the town, who are represented on the committee.

City and North London Railway.—Amongst the private Bills which have passed the initiatory stage of the Standing Orders is that of the Great Northern and City Railway Company, which, by the creation of a new company with capital powers to the extent of £1,500,000 and £500,000 borrowing powers, proposes to construct a new line of electric railway from the Great Northern line near Finsbury Park to Finsbury-pavement, upon the same principle and by the assistance of the same engineer, Mr. Greathead, as that which has been adopted by the already existing line of the City and South London Railway.

London County Council Offices.—The installation about which some comment was recently made, that for the London County Council's offices, is now nearly ready, and will be open for inspection and use shortly. The contract was let, it will be remembered, to Messrs. J. D. F. Andrews and Co., of 41, Parliament-street, for £1,490, the highest tender being nearly double this. It must not be supposed, however, that this was due to the use of Mr. Andrews's concentric wire system, as it was specially specified to have the two-wire conductors in casing. There are nearly 400 incandescent lamps, including fittings, all separately specified.

Chicago Exhibition Committee.—The first meeting of the Electricity Committee was held on Tuesday afternoon, 26th inst. Present: W. H. Preece, F.R.S., in the chair; Sir Frederick Abel, K.C.B., D.C.L., F.R.S., Colonel R. T. Armstrong, C.B., R.E., R. E. B. Crompton, Prof. James Dewar, M.A., F.R.S., Major-General E. R. Festing, F.R.S., Prof. George Forbes, M.A., F.R.S., Prof. G. Carey Foster, F.R.S., Edward Graves, Prof. D. E. Hughes, F.R.S., Gisbert Kapp, J. C. Lamb, C.M.G., W. M. Mordey, J. Fletcher Moulton, M.A., Q.C., F.R.S., Prof. John Perry, D.Sc., F.R.S., Alexander Siemens, Prof. Silvanus P. Thompson, D.Sc., F.R.S., with Sir Henry T. Wood, secretary of the Royal Commission.

Liverpool.—At the weekly meeting of the Liverpool Watch Committee, on Monday, the application by the Liverpool Electric Supply Company, Limited, for the Corporation to consent to a provisional order whereby the power of compulsory purchase should be fixed at 42 years, and the charge for electricity be made 8d. per unit all round, was not granted, the feeling of the committee being that to do so would not be desirable from their point of view. The matter had been reported upon by the city engineer, and last week a memorial was presented to the committee signed by 448 commercial firms in the centre of the city, using 13,379 lamps, asking the Corporation to grant the request of the company.

Leeds.—At a meeting of the Property Committee of the Leeds Corporation held last week, the committee had before them various matters affecting the electric lighting of the Municipal Buildings and Town Hall. It was resolved to recommend the Council to put a fresh installation in the Free Library, and overhaul the existing installation in the rest of the building and the Town Hall. It was stated that the installation in the library was put in when the buildings were erected, and it was now found that the wires were too small to carry the current. All the other parts were in good order. Mr. Nichol, of the borough engineer's office, was appointed to superintend the work, subject to the confirmation of the Council. The cost is estimated at about £500.

Search-Lights for the French Army.—The first of a series of experiments for the purpose of testing the qualities of a new electric light for use in the French Army has been made on the exercise ground at Satory, and a satisfactory result has been obtained. The object of the lamp, which resembles the search-lights used in the navy, is to facilitate night attacks, by rendering the movements of the enemy perfectly visible while concealing those of the offensive side. If adopted, the new light will enable troops to fire at the enemy without furnishing their opponents with any indication to guide their return fire but the flash of the rifles. In order that the lamp may be transported easily from place to place, it is mounted on a light carriage with high wheels, which will enable it to be used on any kind of ground.

Battersea.—The Electric Lighting Committee of the Battersea Vestry reported at the last meeting that they had considered as to the application to the Board of Trade by the Putney and Hammersmith Electric Light and Power Supply Company for a provisional order, and had conferred with the representatives of the company. The committee recommended that the Board of Trade be informed that the subject of electric lighting of the whole of the parish is at the present moment under the careful consideration of a committee specially appointed by the Vestry for the purpose, and that the Board of Trade be asked to defer their final decision upon the application for a short time to enable the Vestry to receive and consider the committee's report upon the subject and to come to a conclusion thereon. The recommendations were adopted.

Primary Batteries.—Offices have been opened at 29, Lloyd's-row, Clerkenwell, by the Marson Battery Company for a new form of primary battery for domestic lighting. When they have had some installations running successfully for a few months we hope they will send us particulars, especially as to cost and trouble of maintenance, as given by the users. We notice that it is claimed—nay, guaranteed—that an output of 1,000 watt hours can be obtained at a cost of 8½d., and they defy any other battery to come near this. We should think so! They give 2¼ amperes for 17 hours on short circuit without attention: all that is needful is a "fresh charge of exhitant"—a new name, we suppose, for "secret solution." There are many other advantages claimed, all of which we hope are possible of demonstration—but we doubt it.

Electric Light Signalling.—Experiments are being carried out on board the Torpedo School ship "Defiance" at Devonport under the direction of the torpedo officers and officers of the Royal Engineers with arrangements for night signalling by means of electric lights placed at the masthead. The experiment has frequently been tried, but hitherto with only partial success, owing to the difficulty of rendering the flashes distinct from each other, the lamps continuing to exhibit a faint glow for some time after the electric current has been shut off. Owing to this disadvantage, signalling by electric lamps can at present only be carried out at the rate of less than 50 words per minute, which is not found to be sufficiently rapid. Incandescent lamps are used, and the connection is made and cut off from the deck. It has been suggested that greater rapidity could be assured by using two sets of lamps.

Electric Sidewalk.—At the World's Fair, Chicago, the electric sidewalk is now in operation. It consists of an endless elevated track, elliptical in shape, 900ft. long, on which two continuous tracks move, a portion at three miles an hour, and a further portion at six miles an hour, the latter being furnished with seats. A passenger can easily step off the stationary part to the slower track and again to the quicker moving track. It thus forms a continuous tramcar, on which the passenger can step off when desired. The system is patented, and this track has been put down to demonstrate the practicability of the system by a company of which Mr. Arnold P. Gilmour is president. It is thought to be a valuable system for moving large masses of people over moderate distances, and will be used for this purpose at the exhibition. It is driven by a 107-h.p. Thomson-Houston motor, and is practically noiseless in operation.

Tenders for Sydney and Melbourne.—Advices from these Australian cities state that both are acting simultaneously as regards electric lighting. It is decided to give time enough in asking for tenders to allow of some of the great European firms to send in tenders for the necessary work. It is almost needless to point out that the firm obtaining either Sydney or Melbourne, or both, or the firms obtaining these contracts will be put into a most favourable position with regard to Australian business. Strenuous efforts will therefore be made to get the contracts, and our large firms must not rest satisfied with mere compliance with the letter of the specification, but must strain every nerve to obtain the work and make it successful. Many of the firms to which we refer have agents in Australia, and ought to be well acquainted with every move of the authorities, hence there ought to be no delay when the time comes to take action.

Thomson Electric Welding.—The Electric Welding Company, who purchased the Thomson electric welding patents at a high figure, have taken offices at 6, Great George-street, where they have photographs of an immense variety of electric welding machines for all purposes, from watchchains up to sheet anchors. The managing director is Mr. M. F. Armstrong; the secretary is Mr. G. Ensor Mount; and the manager Mr. William Parker. Machines have been installed in several parts of the county, besides Birmingham and Newcastle, and specimens are shown, amongst other things, of axes, of which the steel cutting edge is welded to an iron body. Numerous specimens of cannon shell welded by this process were lately on view from the U.S. Navy department. Electrical engineers will await with interest the details of the company's work, which it is probably too early yet to comment upon. The field is large and it is to be hoped the success will be coincident.

Rival Lighting Companies in Holborn.—Mr. Claremont, of the Metropolitan Electric Supply Corporation, waited on the Holborn Board of Works at their meeting last week to ask them not to consent to the application of another company to supply Holborn with electric light. There was not sufficient demand in Holborn, he maintained, to warrant the establishment of another company in the district. His corporation had endeavoured in every way possible to give satisfaction, and had never had a complaint or a breakdown; and, besides, their price was cheaper by ½d. a unit than that of any other company in London. In reply to a member, Mr. Claremont said that the company's station was capable of supplying far more light than they had application for. Mr. Moss, on behalf of the County of London Electric Company, Limited, asked the Board to assent to the application of his company. The Vestries of Clerkenwell and St. Luke had already given, he added, their consent to the application to the Board of Trade. The Board decided to grant the application of the County of London Electric Company, Limited.

A Great Electric Railway Scheme.—A telegram from Dalziel's correspondent at St. Louis, Michagan, says that a company has been incorporated at Springfield, Illinois, for the purpose of constructing an electric railroad from St. Louis to Chicago. The company proposes to lay

a double-track road as straight as an arrow, upon which it [illegible] run electric cars, which will travel at the rate of 100 miles an hour, and thus compass the distance in two hours and a half instead of eight hours, as now. The power station will be at Clinton, Illinois, where the company will work a coal mine of its own, using electric drills and mining machinery. In time, it is added, the line is expected to become a boulevard of farmers' houses, standing on city lots, while behind them will stretch wheat fields. The houses will be lighted and heated by electricity, and reapers, mowers, and thrashers will be driven by electric power. Among the directors is Dr. Wellington Adams, termed the inventor of the first electric motor. Nearly the entire right of way has been secured, and within a few weeks the contracts will all be let out. The company will endeavour to have the line in operation in time for the World's Fair. Another telegram states that the capital is one million dollars, and that Edison's system is to be used.

London Electric Mains. — The London County Council have sanctioned the laying of mains by the London Electric Supply Company in Stamford-street, Waterloo Bridge-road, and Westminster Bridge-road, on condition that the works in Westminster Bridge-road when once commenced be carried on continuously by day and by night until completed; that the mains be laid under the footways, and be kept 9in. below the under side of the paving wherever it is found practicable to do so; that where the mains cross the carriageways they be kept at the same depth below the concrete or the road material as the case may be; that the positions of the street boxes, and the mode of construction of them, shall be submitted to and approved by the Council's chief engineer; that all pipes or openings from or into the boxes shall be of such shape as to remove all risk of injury to the covering of the cables; that all cables crossing the boxes shall be supported from below in the boxes; that all service lines or small cables shall be protected, where leaving the boxes, by an extra lead covering or by wooden stoppers, and shall also have a copper wire of sufficient size carried from the service to the main cable, in good connection with the lead or iron outer casing; and that the ends of all mains terminating elsewhere than in a box shall be securely protected by iron caps, in addition to any other covering.

Electric Traction at Liverpool.—In moving the report of the Liverpool Tramway Company, the chairman referred to mechanical haulage, which they were anxious to see introduced on the line. Compressed air was expensive, and cables necessitated breaking up the streets. "Electricity," he said, "has been tried, and it answers well as a haulage power, but commercially the price is far more than horses. We had an offer for electrical haulage at 7d. per mile, with an additional charge of £1,600 for each car with its electrical machinery attached. The 7d. per mile is much more relatively than the cost of horse haulage, exclusive of the capital outlay of £1,600 for each car, and as we have 234 cars the total outlay would amount to £374,400. The company who made this offer of 7d. a mile, after making a long trial on our streets, offered the Glasgow Corporation the same service at 3½d. per mile, or just one-half the price offered to us. In explanation of this enormous difference they urged the physical difficulties of Liverpool by reason of the hilly streets in comparison with Glasgow. The latter city is considered to have streets with very steep gradients, but that the difficulties of our streets are infinitely greater appears to be quite true, because we have a written statement to that effect from the eminent company who made the trial on our lines during the last two years."

Telegraphing Without Wires.—Among the recent American patents is an interesting one by Edison for transmitting signals electrically without the interposition of connecting wires. In his specification he states he has discovered that, if sufficient elevation be obtained to overcome the curvature of the earth's surface and to reduce to the minimum the earth's absorption, electric telegraphing or signalling between distant points can be carried on by induction without the use of wires connecting the distant points. This discovery is especially applicable to telegraphing across bodies of water, or for communicating between ships at sea or between ships at sea and points on land, it being necessary, however, on land to increase the elevation, and the use of stationary balloons is mentioned. At sea, from an elevation of 100ft., communication can be made to a great distance, and the masts of the vessel, fitted with suitable metal plates, are suitable Connection is made to earth, and the high-resistance secondary circuit of an induction coil is placed in circuit between the condensing surface and the ground. The primary circuit includes a battery and a device for making the signals. Completion of the circuit produces impulses in the secondary, producing electrostatic impulses at the condenser; these are transmitted inductively through the air, and are made audible by the electromotograph in the distant condenser. By repeating the signals from ship to ship communication is to be established over the largest seas, or even oceans, while collisions between ships in fogs would be prevented. It is a very pretty idea worked out from his previous experiments in the induction telegraph, and we hope it may prove successful in practice.

Llangollen.—An installation has been just completed by Mr. William Sillery, of Wrexham, for R. Graisser, Esq., of Argoed Hall, near Llangollen, the proprietor of the Ruabon Chemical Works. The generating plant is placed at the chemical works, and consists of a Crompton dynamo, 110 volts, and a set of 60 accumulators used for lighting the works; arc lamps are also used. During the day the dynamo is run to charge 40 accumulators, 1½ miles away, at Mr. Graisser's residence. The accumulators used here throughout were patented by Mr. Sillery in April last year, manufactured by Messrs. Walker Parker, Limited, Chester. It is interesting to mention in connection with this installation that a third wire for telephone has been successfully erected upon the same poles as the electric leads communicating with the chief offices at Argoed Hall, near Llangollen. The leads cross the River Dee directly, and pass underneath the famous canal aqueduct built 100 years ago, then the wonder of the age. Mr. Sillery has also been directed by Mr. Graisser to devise a scheme to drive his works by electricity, obtaining the necessary power from the River Dee, where there is an abundant supply of water.—An installation has further just been completed at the mansion of E. S. Clark, Esq., proprietor of Llay Hall Colliery, driven from a Crompton dynamo, three-quarters of a mile distant, at the colliery, into 43 accumulators, E.P.S. type, 31-plate cells, and giving entire satisfaction. Mr. Sillery is also now placing the electric light down the pit, for which purpose four dynamos are being installed, with engine and house on surface to act as reserves for the Llay Hall Colliery, to which colliery he is electrical engineer. The cables and wires used throughout, also insulators, were supplied by the Telegraph Manufacturing Company, Helsby, near Warrington.

Schanschieff Batteries.—We were shown the draft prospectus of a new company the other day, with the imposing title of the Central Electric Company, with some well-known names as directors; capital £50,000. Thinking it was possibly a new railway or electric light company, we

looked at it with interest, and with some surprise saw—Schanschieff battery again. Now we have no wish whatever to prevent the Schanschieff battery being put on the market. It is a good and useful battery, if the price is not considered. It might possibly be of use to some instrument maker to take up this battery and make a special department for its supply for philosophical or lecture purposes, and so forth. But a company for £50,000 can only attempt work on false pretensions. It may be worth while to mention a few facts with reference to previous attempts and their results. The Schanschieff battery was the object of reports by high authorities, who accepted the statement of cost of material from the inventor. A syndicate was formed, and afterwards an enormous company, with a quarter of a million capital, if we remember rightly. But facts as to cost leaking out, this company returned the money subscribed, and the whole thing fell through. It has apparently now got into other hands, and attempts made to revive the company. Do these persons know what the cost of a unit of electricity by the Schanschieff battery really amounts to? Is it 7s. 6d. a unit, and, if so, how can they expect to get the battery taken up on any scale to justify thousands being subscribed? Do they know whether the cost of Schanschieff liquid for a few hand lamps at the Greenwich Observatory last year came to something like £30, while the present cost of bichromate cells and accumulators only cost about one-tenth of this for liquid? Anyone who knows the facts could hardly dream of using batteries causing so much expense, and we have not yet heard that anything has been done to reduce the cost to within even barely practicable limits. The Central Electric had better use dynamos and send round charged cells. There might possibly be use and profit in that proceeding.

Board of Trade Laboratory.—Captain Cardew and Mr. Rennie have been working hard to get the Board of Trade testing laboratory into complete order, so that the legal units of electrical supply to be adopted by Government may be determined ready for adoption at the forthcoming parliamentary session. The aim in these new tests has not been at all to make new determinations of the units, but to so accurately measure correlatively the ampere, the volt, and the ohm, by certain resistances and balances, that real units for comparison can be placed in the Board of Trade laboratory, and these can be certified and acknowledged as the legal units for the sale of electrical energy in Great Britain. For one thing, delay has arisen because they have not yet obtained the definite form of current-measuring apparatus from the Cambridge Instrument Company. A specimen balance is now in the laboratory, but does not entirely embody the needed mechanical construction. Primarily, the units required are first a distinct length of metal to be known as the legal ohm. This will be obtained from makers exact to the nearest degree possible to that of the true ohm as now known, and three copies will also be kept for comparison. Then careful experiments with Clark's standard cells, and with the voltameter test, will determine the strength of current of a legal ampere, and this again combined with the resistance will give the legal volt. The peculiarity of the instruments will be that the magnetism of iron does not enter into the tests; the attraction and repulsion of the currents will be weighed or balanced by actual weights, and these weights, under stipulated conditions, will represent the legal units. The laboratory has now an alternator driven by a motor supplying four to 1,000 volts alternating current, a Brush machine, specially made, giving up to 2,000 volts continuous. A 10,000-volt Ferranti transformer has been recently added, and a 50,000-volt transformer will also shortly be in use. The only actual work of the laboratory at present has been in testing meters, of which may be mentioned Schallenberger's, the Thomson-Houston, Ferranti, Teague, Frager, Desruelles et Chauvin, and others. These are tested for the range of their capacity, for length of run, for standing idle, for alternations of temperature, and so forth. The laboratory cannot fail to be one of the most important factors in British electrical engineering. The electrical profession may well be thankful to the energy and patience of the gentlemen who have it in charge.

Laing, Wharton, and Down.—A paragraph has recently appeared that Messrs. Laing, Wharton, and Down have removed from Bond-street and taken offices at 38, Parliament-street, and again a statement appears that Messrs. Laing, Wharton, and Down have not left Bond-street, and continue their work there. To those who know the position these statements are perfectly clear, but as there are probably many who do not know, we will explain the matter a little. Messrs. Laing, Wharton, and Down—of whom the partners are now Mr. Wharton, Mr. Down, and Mr. Davies—are a private firm carrying on the business of electrical contractors, manufacturers, and artistic fitting suppliers at 82A, New Bond-street, and City offices at 17, Gracechurch-street. They are open to supply and contract for all house work, mansions, fittings, and the general work of a high-class electrical contracting firm Besides this, there is the Laing, Wharton, and Down Construction Syndicate, Limited—a perfectly distinct affair — a limited company with the capital of £100,000. This company has really no connection with the first, except that it is managed by the three members of the first-mentioned firm, though we believe Mr. Wharton is principally occupied in its management. The Construction Syndicate undertakes large financial and company work in electric lighting; it owns the Thomson-Houston patents, and is proprietor of the works at Waterford, Reading, and Weybridge, besides having sold the plant to, or helped to form, the companies at Exeter, Bath, Taunton, and Fareham, besides the City of London. A similar operation is being carried out at Reading. The directorate of the Construction Syndicate is a peculiarly strong and interesting one. The chairman is Colonel Martindale, C.B., R.E. (retired), who takes great interest in electric distribution problems, and is one of the directors of the City of London Company. Next, Mr. Percy Westmacott, who was one of the founders, with Lord Armstrong, of Armstrong, Mitchell, and Co., at one time managing director of that company, but now an ordinary director, his great wealth evidently allowing his previously busy life to be taken more easily. The third director is Mr. Wilson Crewdson, connected to the Crewdson, Waterhouse, Barclay, and other banking interests, an influential man to have on any board. The last is Dr. Merz, of Newcastle-on-Tyne, chemical manufacturer, one of the founders, with Mr. J. W. Swan, of the original Swan Company, and an accomplished chemist and engineer, with great organising powers and knowledge of business. The Laing, Wharton, and Down Construction Syndicate, though a private limited company, is, of course, public to the extent of publishing its accounts in the usual way, and has paid a 5 per cent. dividend for the last three years. They also have, besides the Thomson-Houston patents, the rights in the Elihu Thomson high-rate alternator, which will probably be shown at the Crystal Palace Exhibition, lighting lamps from a single wire; with new motors, the Van Depoele pulsating-current rock drill, electric cranes, pumps, and other novelties, which cannot fail to create great interest at the Exhibition.

THE DETERMINATION OF THE EFFICIENCY OF DYNAMOS.

BY GISBERT KAPP.

(Concluded from page 88.)

This experimental evidence, then, disposes of the question why the efficiency of a machine should not be determined in the manner above indicated. The answer is that if tested in this manner the efficiency comes out too high, and if we wish to determine the efficiency accurately we must either test two machines together, or, if only one machine is available, we must from a previous test know the rate at which the losses increase with the load.

Fig. 1 shows the arrangement for an efficiency test when all the three machines are coupled in series. B and C are the armatures of the machines to be tested, and A is that of the machine supplying the current. The fields of the three machines are separately excited by a machine, D, and are indicated by the coils F_a, F_b, F_c, F_d. Ampere-meters and voltmeters would be applied to the field circuits, F_b and F_c, to determine the exciting energy, but these instruments are not shown in the diagram in order to avoid useless complication. A rheostat, R, is inserted into the field of dynamo B so that it may be weakened, and the current passing through the machines B and C is read on an ampere-meter, *a*. A voltmeter, V, is also connected up, as shown, so that by switching it on to contact *b*, we get the brush voltage of B, and by switching it on to contact *c* we get the brush voltage of C.

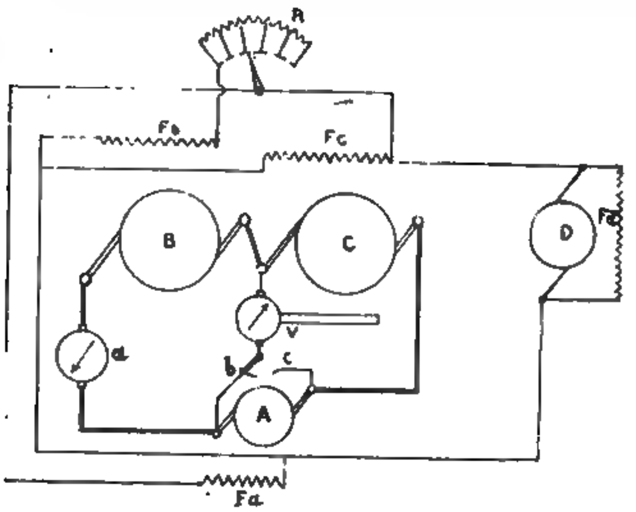

FIG. 1.

Since B and C are mechanically coupled they revolve at the same speed, and the voltage of B is therefore lower than that of C, the difference between the two readings being the voltage of the machine A, which supplies the power to keep the whole system going. The machine C works as a motor and B works as a generator. Calling e_c and e_b the respective brush volts, and C the current, we have the following relations:

Power supplied by A $= C(e_c - e_b)$
Power supplied to C $= C\,e_c$
Power obtained from B $= C\,e_b$

We neglect here the resistance of the connecting cables, since this can be made as small as desired. Now the ratio between the power obtained from B and that supplied to C is obviously the efficiency of the two armatures considered as one system, and since the current is the same (or can be made to be the same by taking the two volt readings in quick succession) we find that the efficiency is simply given by the ratio of the two voltages. The efficiency of each armature by itself is then given by the square root of this ratio, or

$$\eta = \sqrt{\frac{e_b}{e_c}}.$$

All we have therefore to do to get the efficiency is to adjust the rheostat, R, and the power supplied to dynamo A in such way as to obtain the normal current as indicated on the ampere-meter, *a*, and the normal speed of the machines B and C. Then by shifting the voltmeter contact several times between *b* and *c* we obtain with great accuracy the two voltages, and the square root of their ratio gives the efficiency. It is important to observe that neither the ampere-meter nor the voltmeter need be correctly calibrated. As far as the ampere-meter is concerned, all we have to do is to take care that it shall indicate the same current during the whole time that volt readings are taken, or that we reject those readings which happen to have been taken while the current was different. The voltmeter need not indicate true volts, but it must have the same percentage error within the range of readings required. Thus, if it is wrong by 5 per cent. at 100 volts, it must also be wrong by 5 per cent. at 90 volts and 110 volts. These limits suffice in practice, since with modern machines an armature efficiency of less than 90 per cent. need hardly be expected, and between such narrow limits even an ordinary commercial voltmeter may be relied upon to have nearly the same percentage error. A slight difference in the percentage error of the two readings will affect the result, but not to the full extent of this difference, since the efficiency is not the voltage ratio itself, but its square root. Say, for instance, that the indicated voltage ratio is ·88, but that there is a variation in the percentage error at the lower reading of 2¼ per cent. Then the true ratio would be ·86. The square root of ·88 is ·938, and that of ·86 is ·927. In estimating the efficiency we would then have an error of 1·1 per cent., although the voltmeter was wrong by 2·25 per cent. But even this error can be

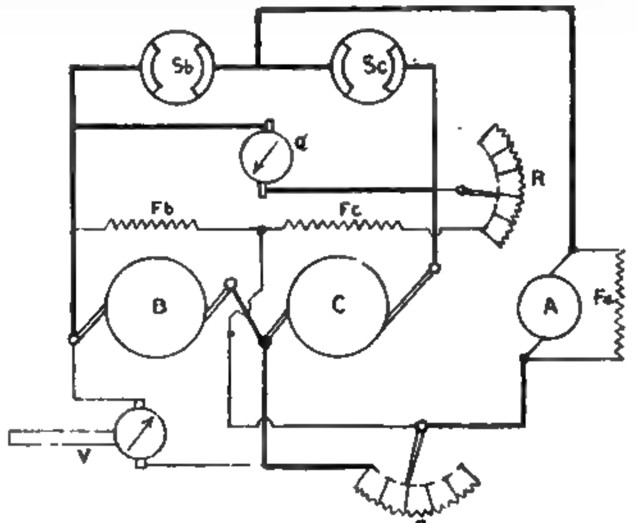

FIG. 2.

eliminated by making a second test, in which the rheostat is placed in the field circuit of C, so that B becomes the motor and C the generator, and then taking the mean between the two determinations.

It will be seen that the method here described is eminently suitable to give accurate results, even if our instruments are not absolutely reliable, but in practice there arise certain difficulties which sorely tax the skill and patience of the experimenter. The different adjustments which have to be made react on each other in a most bewildering way, and it is not always easy to see what should be done to get the system running under normal conditions. One difficulty the writer found was the tendency of the armatures B and C either to stop running altogether or else start off at racing pace. This difficulty was overcome by driving the dynamo A by an engine without a governor. In this way the engine itself took care to deliver a nearly constant current to the system, and the adjustment of the rheostat did not affect the current, but only the speed and voltage. Another difficulty is due to the fact that the total amount of power required to keep the system going is small in comparison with the work which may be stored in the revolving mass of the armatures, so that the effect of an adjustment at either the rheostat or any of the brushes is not immediately seen. The cure for this evil is, of course, to make all adjustments very gradually and not to hurry the test, but work patiently. Observing these and other precautions, which it would take too long to detail,

it is quite possible to make a very reliable efficiency test, but the plant required is rather elaborate. We must have two auxiliary dynamos and two steam engines, one without a governor, and giving exactly the torque corresponding to the current, and the machine driven by it must be of low voltage and large current, all of which requirements are not easily fulfilled.

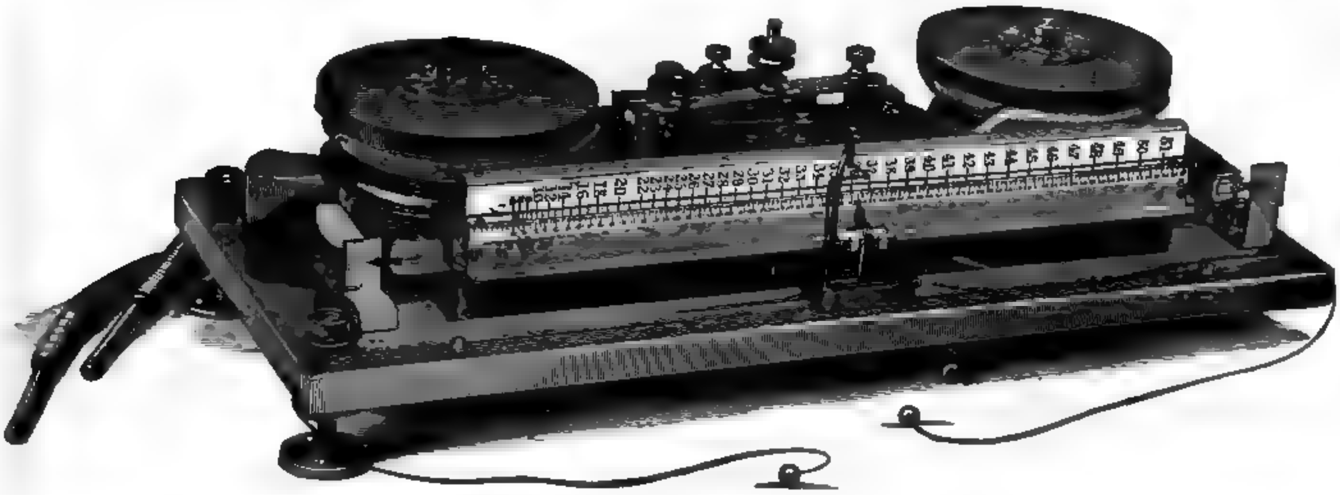
In these and other respects the method of parallel working is preferable. We require only one auxiliary dynamo of normal voltage, and giving a small current, and the engine may be of any convenient size, provided it is governed for constant speed. Fig. 2 shows the arrangement for this method of testing. B and C are again the two armatures mechanically coupled, F_b and F_c are their field coils, and in the latter is inserted the rheostat, R, by which the magnetisation of C may be sufficiently weakened to cause this machine to work as a motor. S_b and S_c are switches, which for the moment we suppose to be both closed. The voltage on both armatures is indicated on the voltmeter, V, and r is a rheostat chiefly used for starting, but also available if it be desired to work the machines to be tested at a lower voltage than that of the supply machine, A. This machine only gives the current required for excitation, and the difference between the current absorbed by C and given out by B. Suppose, now, everything to be properly adjusted, and the system to be at work. If we open switch S_c the auxiliary current will flow through switch S_b, and after being joined by the current coming from B will flow through the ampere-meter, a, and through the armature C. By opening the switch S_c, we therefore measure on the ampere-meter the current which C absorbs when working as motor. Similarly, if we close S_c and open S_b, we measure on the same ampere-meter the current which the generator B is delivering, and it is important to note that in both cases the current passes through the ampere-meter in the same direction, so that we need not fear the disturbing effect of residual magnetism, if any. If during the two readings the voltage remains the same, then the ratio of the two currents gives the efficiency of the two armatures considered as one system, and the square root of this ratio gives the efficiency of each armature, or

$$\eta = \sqrt{\frac{e_b}{e_c}}.$$

It is again obvious that the instrument need not indicate true amperes as long as the percentage error within the limits of the two readings is constant, and if we have a suspicion that the percentage error is not constant we need only put the rheostat into the field circuit of B and repeat the test, taking the mean of the two tests. One advantage of the method shown in Fig. 2 is that by it racing of the machines, or indeed any considerable variation of speed, becomes impossible, so that our adjustments are not liable to be disturbed by the inertia of the armatures. We need only adjust for current by shifting the contact on R until a little more than the normal current passes through C, and a little less than the normal current passes through B. If the steps on R give too coarse an adjustment, we can get the fine adjustment by moving the brushes on C.

THE CRYSTAL PALACE EXHIBITION.

One of the exhibits that will least attract attention from the thousands who go to see light and colour—who go with the intention perhaps of seeing how the light would suit their rooms—ought to receive the greatest possible attention from electrical engineers. We refer to Stand 151, of **Mr. J. White**, of Glasgow, who shows, amongst other things, a complete set of Sir W. Thomson's standard measuring instruments. While we agree that for practical use in central stations such instruments would be out of place, they are absolutely essential for all laboratory work. This stand was complete in time for the opening of the Exhibition. It is admitted by all who know aught of the subject that the greatest attention has been paid by Sir W. Thomson to electrical measurement. The outcome of this attention is the magnificent set of apparatus shown. In our issue of August 29, 1890, p. 173, and subsequent issues in the same volume, see pages 211, 237, 284, and 332, we illustrated and described most of these instruments. The value, however, of such instruments to the profession will be sufficient excuse for this further reference.



Sir William Thomson's Deka-Ampere Balance.

The standard direct-reading electric balances are founded on the mutual forces, discovered by Ampère, between movable and fixed portions of an electric circuit. The shape chosen for the mutually-influencing portions is circular, and each such part is called for brevity an ampere ring; or sometimes simply a ring, whether it consists of only one turn or of any number of turns of the conductor.

Cunynghame's Magnetic Cut-Out.

In each of the balance instruments, except the kilo-ampere balance, each movable ring is actuated by two fixed rings—all three approximately horizontal. There are two such groups of three rings—two movable rings attached to the two ends of a horizontal balance arm pulled, one of them up and the other down, by a pair of fixed rings in its

neighbourhood. The current is in opposite directions through the two movable rings to practically annul disturbance due to horizontal components of terrestrial or local magnetic forces. In the kilo-ampere balance the whole current passes through a single fixed ring and divides through two halves of a movable ring, which are urged one up and the other down by the resulting amperian force.

In all the instruments the balance arm is supported by two trunnions, each hung by an elastic ligament of fine wire, through which the current passes into and out of the circuit of the movable rings or ring.

In all the balance instruments, in which the movable ring is between two fixed rings, the mid-range position of each movable ring is in the horizontal plane nearly midway between the two fixed rings which act on it. The current goes in opposite directions through the two fixed rings, so that the movable ring is attracted by one of the fixed rings and repelled by the other. The position of the movable ring equi-distant from the two fixed rings is a position of minimum force, and the sighted position, for the sake of stability, is above it at one end of the beam and below it at the other, in each case being nearer to the repelling than to the attracting ring by such an amount as to give about $\frac{2}{10}$ per cent. more than the minimum force.

In the balance instruments to measure alternate currents (which may be also used for direct currents) of from one ampere to 600 amperes the main current through each circle, whether of one turn or of more than one turn, is carried by a wire rope of which each component wire is insulated by silk covering, or otherwise, from its neighbour, in order to prevent the inductive action from altering the distribution of the current across the transverse section of the conductor.

The balancing is performed by means of a weight which slides on an approximately horizontal graduated arm attached to the balance; and there is a trough fixed on the right-hand end of the balance into which a proper counterpoise weight is placed, according to the particular one of the sliding weights in use at any time. For the fine adjustment of the zero a small metal flag is provided, as in an ordinary chemical balance. This flag is actuated by a fork, having a handle below the case outside, as shown in the illustration. To set the zero, the left-hand weight is placed with its pointer at the zero of the scale, and the flag is turned to one side or the other until it is found that, with no current going through the rings, the balance rests in its sighted position.

To measure a current, the weight is slipped along the scale until the balance rests in its sighted position. The strength of the current is then read off approximately on the fixed scale (called the inspectional scale), with aid of the finely-divided scale for more minute accuracy. Each number on the inspectional scale is twice the square root of the corresponding number on the fine scale of equal divisions.

Crompton's Projector—Stand No. 1.

The slipping of the weight into its proper position is performed by means of a self-releasing pendant, hanging from a hook carried by a sliding platform, which is pulled in the two directions by two silk threads passing through holes to the outside of the glass case.

Four pairs of weights (sliding and counterpoise), of which the sledge and its counterpoise constitute the first pair, are supplied with each instrument. These weights are adjusted in the ratios of 1 : 4 16 : 64, so that each pair gives a round number of amperes, or half-amperes, or quarter-amperes, or of decimal subdivisions or multiples of these magnitudes of current on the inspectional scale.

The useful range of each instrument is from 1 to 100 of the smallest current for which its sensibility suffices. The

ranges of the different types of this instrument regularly made are—

I.	Centi-ampere balance :	From	1 to 100 centi-amperes.
II.	Deci-ampere	" "	1 to 100 deci-amperes.
III.	Deka-ampere	" "	1 to 100 amperes
IV.	Hekto-ampere	" "	6 to 600 "
V.	Kilo-ampere	" "	25 to 2,500 "
VI.	Composite	" "	·02 to 500 "
			and from 100 to 25,000 watts (at 100 volts.

Besides the balances, the stand contains other instruments, which will be referred to later on.

becomes too great for the position at which it is set. In the old form alteration in the current at which the cut-out was to act could only be obtained by shifting the core of the solenoid, and as the ends dip into the mercury, this often deteriorates the contact considerably. In the improved form, embodied in Bryan's patent, the current passed round a pivoted solenoid, whose ends dip into mercury, the solenoid being drawn back on a curved core when the current exceeds a certain strength. The core is held by a set screw and made adjustable, and by altering its position the strength of current at which the cut-out is to act can be accurately determined. A number of these instruments, of various sizes, are shown

CAMEL WITH ELECTRIC LIGHT

CRYSTAL PALACE PANTOMIME 1892

The exhibit of **Messrs. Woodhouse and Rawson United** is very interesting from several points of view. One of Kingdon's alternating dynamos, as used at Woking, is the most important exhibit here, and will be a source of interest—the only other time it has been exhibited being at Frankfort. It is probable, however, that the attention of ordinary visitors will be most given to the flashing of incandescent lamps above the stand. The well-known diamond-shaped patterns, with the initials "W. & R."—their trade-mark—are formed in incandescent lamps, and will alternately be kept flashing on red and blue, after the method adopted with conspicuous success as a sign at the Trocadero, in Piccadilly. Switches in great variety are shown—single and double pole, quick-break. Amongst the cut-outs is a new and improved type of the Cunynghame magnetic cut-out, which we illustrate herewith. This cut-out acts, as is well known, by breaking a mercury contact when the magnetic effect of the current in the coil at the Crystal Palace Exhibition, having ranges of 1 to 40 amperes, 30 to 100 amperes, 100 to 250 amperes, 250 to 600 amperes, 600 to 1,000 amperes, thus forming a series of reliable current-breaking instruments.

Perhaps it was injudicious to take this sketch of **Messrs. Crompton's** Stand No. 1, but it will serve to show that they are exhibiting at least two projectors. We remember Mark Twain has a funny way of telling what certain marks in his sketches represent. It will be necessary to do this as regards the remarkable-looking things depicted as resting upon the table. They do not represent flat wires, but instruments of some kind. The fact is that when Mr. Bowles was making his sketch, this stand was hardly ready, whatever may be its condition now; and having on two separate occasions made up his mind to take the sketch, he would not be baulked at the second attempt. There is no mistaking the apparatus at the top of the wooden structure, which some-

one has called a "conning tower." It represents a conning tower about as much as a broomstick would, but there is no accounting for such mistakes. Manufacturers of electrical apparatus are always ready with a blessing for everything connected with projectors, for was it not the value of projectors in naval work that in the dull, dreary period of waiting for orders to instal light and power brought orders which kept the works agoing? The permission for ships carrying projectors to go through the Suez Canal by night brought orders from private firms; the use of projectors in warships brought orders from the Admiralty. The use of projectors, too, meant the use of dynamos, of engines, and, if we mistake not, had very much to do with the general adoption of electric light on board ship. At any rate, Messrs. Crompton, Messrs. Siemens, the Brush Company and others, have done a lot of work in this direction. The number of men who know the whole history of electrical development during the last 15 years is comparatively small. Few of the telegraphists troubled about the interloper about which so great a fuss was being made 15 years ago, and many of the prominent names of to-day are of those who entered the industry after the stir had been made. Mr. Crompton, however, was interested in the work from the beginning. Our recollection may not be verbally accurate, but we imagine it will be generally so. In the very early days of the electrical era Mr. Crompton was managing director of the Stanton Iron Works, and a partner in a small manufacturing business at Chelmsford principally connected with hot-water apparatus. Well, at one particular period some urgent work was required for the Stanton Company, and Mr. Crompton wanted men to continue the work night and day. But to work at night means light, and necessity led to the designing of his first arc lamps. They were successful, and were made in the small works at Chelmsford. Mr. Crompton soon saw there was money in electrical work, and, pitching cares to the winds, he went for it in a lump. He got it, too, as anyone will see who visits the Chelmsford and the Lillie Bridge Works of to-day and compares them with the old works of Dennis and Crompton. The Gramme patents controlled the make of one type of dynamo, the Siemens's patents controlled another type, but Mr. Crompton managed to get a type which interfered with none of these patents. He produced a thoroughly good knockabout machine. Of this we can speak with some degree of authority, as for the space of one or two years we had such a machine running under all conceivable conditions at our own house, and from first to last never had any trouble with it, yet as soon as the Gramme patents lapsed that type of armature superseded almost all others, and the Crompton-Burgin is now ancient history. As we say, Mr. Crompton's first experiments were in the direction of arc lighting, so that when the need for projectors was made clear, it is easily understood how he would give great attention to the matter. The outcome of this experience can be seen in the apparatus shown at the Palace. The projectors carry self-regulating arc lamps of 30,000 c.p.; and that their mechanical construction is excellent can be ascertained by examination.

Deane Brand as the Demon King—Crystal Palace Pantomime.

Kate Chard as the Fairy Queen—Crystal Palace Pantomime.

Each projector has a horizontal movement and a vertical movement. The horizontal movement can be all round the circle, but any one position can be retained by a clamping arrangement. Similarly, a large vertical range can be obtained. The lamp can be properly focussed by means of a screw; all the parts are simple—the gear strong and well made and of the best material. One of the projectors shown will be supplied with current from a battery of Crompton-Howell secondary batteries to be seen in the Machine Department. It seems almost a pity that some enterprising exhibitor did not think of putting a couple of projectors on the top of the Crystal Palace towers. It might have been a somewhat costly exhibit, but it certainly would have been an effective one. A novel departure at Stand No. 1 is that electrical measurements are to be taken, so that he who runs may read. It is to be hoped that one of those charming parrots at the end of the North Nave, or some equally eloquent speaker, will be pressed to explain simply to the audiences what is being done and why it is being done—but of this by-and-by.

It is not our province to discuss the merits or demerits of the **Crystal Palace Pantomime**. We have, however, to confess to a weakness for spectacular displays and tales from the Arabian Nights. We have usually found, too, that many of those who talk loudly about the degeneracy of pantomime manage soon after Boxing Night to familiarise themselves with the various pantomimes going. But the elder folk have no business to pass judgment upon this class of entertainment; it is sufficient if the younger generation are delighted. The first object of every caterer for public amusement is to make it pay, and whenever the amusement is of a healthy and innocent character it is the duty of the scribblers of the Press to assist in this end, for "All work and no play makes Jack a dull boy."

From year to year the Crystal Palace authorities produce a pantomime. This year Mr. Horace Lennard and Mr. Oscar Barrett have revived our old friend, "The Forty Thieves." As is usual, Mr. Barrett has called to his aid the most popular ditties of the day, and they most unmistakably give life and go to the performance. Of course the greatest attention has been paid to the spectacular part of the business, and gorgeous dresses, the sheen of polished metal, the flashing of colour from cut and tinted glass, with appropriate scenery, welds together an entertainment which for brightness, light, and colour has never been surpassed on these boards. We believe Mr. Barrett, jun., has painted the scenes. To this gentleman, too, we are indebted for many courtesies and much information. Electricity has been called in to play a moderate part in the spectacle. It was originally intended to use it to a much greater degree. Of the pantomime itself, we may sum it up in four lines from Calderon, as consisting of:

> In a word, delicious joys,
> Raptures, ravishments, entrancements,
> Pleasures, blisses, fondest favours,
> Sports and plays, and songs and dances.

These harmoniously intermingled, the eye and the ear enchanted, with the genuine flavour of clown and pantaloon thrown in, give some four hours of absorbing delight to the youngsters, and they view a scene

> Which comes . . . with songs and music,
> And a syren train to charm them.

But to our more prosaic task. How is the electric light used? Imagine the scene, which, of course, must include the beautiful Fairy Queen (Kate Chard), the Demon King (Deane Brand), and their attendants. In the "Forty Thieves" Cogia (S. Wilkinson) must be represented. Then we have the procession, and the ballet, and the transformation scene. The Fairy Queen, whose wand is more powerful for good than the demon's machinations are for evil, carries a brilliant lamp above her forehead, the current for which is obtained from a small secondary battery. Similarly the Demon King is provided with a lamp, while Cogia has three—one on the crown and two at the termination of long ringlets. In these cases the battery and connections are hidden within the folds of the dresses of the artistes. Two groups of attendants in the procession carry spears with decorative coloured streamers, and from just below the spear head appears a twinkling point of fire, as if the spear had a diamond setting. The effect is very good. The batteries supplying current to the spear head lights are carried in a small metal pocket on the spear shaft, hidden by the streamers. The secondary batteries have been supplied and

S. Wilkinson as Cogia—Crystal Palace Pantomime.

A Dainty Amazon—Crystal Palace Pantomime.

are maintained by the Mining and General Electric Lamp Company, whose stand we illustrated in our issue of Jan. 15th, p. 55. The current for charging the batteries is obtained from the Sydenham central station, just erected for the Electric Installation and Maintenance Company, by Messrs. J. E. H. Gordon and Co. In the transformation scene a number of camels are depicted, each carrying a lady, above whose head is a corona of incandescent lamps. These lamps are fed by means of flexible connections, easily connected to appropriate terminals in the stage floor and on the camels. The effect obtained is brilliant, and the audience see—

> Those who wear the rainbow's dress,
> Who within the car triumphal
> Above the busy throng are seated
> 'Neath a canopy, wherein
> Purple, pearl, and gold are blended.

Again the prosaic. The stage connections and fittings have been, we believe, done by Messrs. Rashleigh Phipps and Dawson, the current being from the ordinary Palace supply, by the Gulcher Company.

CORRECTION.

Rotary-Current Plant.—*Owing to the inaccurate knowledge of our correspondent, the statements given in our note last week relating to the above apparatus in this country were incorrect. Mr. Henry Edmunds is the only representative of the Drehstrom interests here, and we regret the error of having connected the names of other gentlemen therewith.*

THE CRYSTAL PALACE EXHIBITION AND LOCAL AUTHORITIES.

It may be supposed that as this Exhibition approaches completion many of the exhibitors are thinking over the best way to make it pay. The various exhibits are of diverse character, and purchasers of one class of goods are only indirectly purchasers of another class. Thus, the wealthy owner of a country house may be directly interested both in generating plant, and in fittings, but the resident of a London mansion has little concern with the generating plant; his examination begins and ends with the fittings. Others there are who, passing by the fittings, care only for the generating plant. It must not be expected, however, that a great amount of business will be the direct outcome of the Exhibition: in most cases the ground will be merely laid for future approach and negotiation. It is well known that a number of local authorities have already made arrangements for the supply of electrical energy, either by erecting their own stations or backing up private companies. Many more authorities are considering the question, and it is absolutely certain most of the remainder will join the rolling ball of progress. The great manufacturing companies exhibiting at the Palace are more concerned with what the local authorities do and think than with any other class of visitor. Each, no doubt, would prefer to see all the local authorities one after the other coming to their private place of business or factory, and being there convinced that that firm or company was really the very best to carry out proposed work. That is a natural want—heads of firms and managers of companies may want, but cannot always obtain. The probability is that many of the local authorities will organise deputations to investigate the lighting apparatus at the Palace, and when no such deputation is sent to represent the authority, the engineer of the authority will be instructed to report thereon. If this should be the case, the exhibitors at the Palace ought to take care to be *well* represented. The ordinary stand representative is not what is required, but men of the world, men of business tact and ability, not eloquent scientific talkers. While the members of the deputations may not be conversant with matters electrical, and will certainly want to know more about interference with streets, Board of Trade requirements, obtaining of money, repayments of loans, mechanical construction and strength, they will, of course, require to know generally about dynamo, motor, and lamp efficiencies. They will also be interested to learn as much as possible about the "meters" proposed to be used to record the amount of electric energy consumed. There need be

no laboured explanation, but it would be advisable for the larger exhibitors to have meters at work, and be ready to explain their action. Depend upon it, there is instilled into men's minds a liking to return a compliment, and a clear explanation of apparatus to visitors will enable them to enlighten their colleagues and others upon points not usually well understood—will most likely bring them back to obtain further information when the progress of the work demands it. We have gone again and again to half-a-dozen exhibits to find no one at hand to explain anything, and no doubt visitors have done so likewise. The visit of formal deputations may usually be known beforehand, and it will no doubt be easy to arrange for these field days, but, at the same time, the unknown and the casual visitor ought not to be neglected.

THE PALL MALL COMPANY.

A long, but not altogether harmonious, meeting of this company was held on Tuesday last, and is fully reported in our present issue. The report is so full of pleasant, or unpleasant, surprises that it will prove interesting reading. There is, however, only one point to which we would now draw attention—founders' shares. This class of share is, in the majority of cases, merely a means to an end. The end is the delusion of shareholders. One of the directors of the Pall Mall Company failed to secure re-election at the meeting, and his co-directors demanded a poll, which takes place next week. The reason assigned for opposing such election was dabbling in founders' shares on the Stock Exchange, and a peculiarly rapid depreciation of the quotation for such securities. A dozen or so very pertinent questions were asked at the meeting, but in the end the report of the directors was adopted, so that whatever they may be thought to have done amiss is thus condoned. We suppose it must be granted that a man can sell his shares when and how he pleases, so that no reason exists for not selling founders' shares. We do not object to the selling—we object to their existence.

PROF. G. FORBES, F.R.S., ON DISTRIBUTION.

From year to year we have to acknowledge indebtedness to the Society of Arts for arranging at least one series of Cantor lectures upon electrical subjects. It will be remembered that last year Mr. G. Kapp gave an excellent series of lectures upon the transmission of power. The course of lectures commenced last Monday by Prof. G. Forbes, F.R.S., under the auspices of the society, is on electrical distribution—one of the most important subjects for the consideration of electrical engineers, and one to which Prof. Forbes has paid great attention. Eight years ago he gave a series of Cantor lectures upon the same subject, hence the comparisons he is able to make during the present course cannot but be valuable. It is well known that the society publishes these lectures in its *Journal*, and it has always been our custom to await this official publication before giving the lectures in our columns, because the lecturers, as a rule, merely indicate certain portions of their subject, giving the complete figures, details, and illustrations in the printed text. Of necessity, the first lecture in the present course was general rather than particular. The lecturer called attention to his work of eight years ago, and pointed out that then the tendency of practical men was wholly in favour of direct low-pressure systems. Since then, however, great advances have been made in alternate-current high-pressure systems, and, above all, in that useful accessory to central station work—the secondary battery. Eight years ago distribution rested with direct, multiple, and multiple series work. Now we have developed the three-wire and even the *n*-wire system. Prof. Forbes described at considerable length the system of distribution which required multi-feeding points, and gave some statistics as to the proportion between weight of feeders and weight of distributors in special installations, also the cost per yard run of several typical installations—such as the Kensington and Knightsbridge, the Berlin, and Clichy secteur in Paris. One point brought out by the lecturer during the course of the evening appeals to financiers. Many hundreds of tons of copper are used in mains, and it is by no means difficult to obtain advances of money upon the security of this copper.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MAINS IN BATH.

SIR,—My attention has been called to a notice in your paper in which it is stated that the interruption of the light to certain lamps in Bath was due to contraction and expansion in the joints of the main.

No such thing has ever happened. Certain lamps have been extinguished for a short time on two occasions lately, but in each case the fault has been caused by bad workmanship on the part of the Bath Company's men, who have recently carried out alterations to the lamps.

There has been no contraction or expansion on the mains at their joints or elsewhere, and the Bath Company have had no trouble whatever arising from them.

As I have been called in to repair the defective wiring in the lampposts, I can speak on this subject with absolute knowledge of the facts.—Yours, etc.,

T. O. CALLENDER, Manager.

Callender's Company, 101, Leadenhall-street, E.C.,
January 26th, 1892.

ELECTROLYTIC LAW OF LEAST ENERGY.

SIR,—In a paper by Mr. G. C. V. Holmes, page 92, on the "Modern Applications of Electricity to Metallurgy," I note this remark, that metal will be first deposited from the solution which "requires the least amount of energy. This law was first stated by Dr. Kiliani, of Munich, etc., in the year 1885. The subject-matter of this law is a very large one."

I am not unused to seeing ideas which I have spread broadcast attributed to others, but this, as the French say, is *un peu trop fort*. The law, "Dr. Kiliani's law," is of my own formulation, and may be seen referred to at times as "Sprague's law."

I cannot say at what time it was conceived in my mind,

nor does it much matter; but in vol. xx., p. 2, of that paper of world-wide circulation, the *English Mechanic*, in September, 1874, it was first published in these words: "Let us substitute for the idea of *secondary chemical* action, this new definition of the action at the electrodes which will embrace all the facts. *At the electrodes those ions are set free* which absorb, *in becoming free*, specific energy."

Under the head of "General Law of Electrolysis," that statement has appeared in two editions, each 2,000 copies, of my "Electricity; its Theory, Sources, and Applications," both published before the date of Dr. Kiliani's paper, and in both I point out the resemblance of this law to the effects of destructive distillation. I may add that my definition was published years before even Berthelot formulated his chemical law of "maximum work," and in my second edition I said: "It is evident that M. Berthelot's law of "maximum work" is the converse of the general law of electrolysis which I have formulated."—Yours, etc.,

JOHN T. SPRAGUE.

MEDICAL ELECTRICITY.

SIR,—My attention has been called to the note on this subject in your issue of the 22nd inst., in which you observe that Mr. H. Newman Lawrence is attempting to apply electricity scientifically to the relief of paralysis. May I be permitted to state that Mr. Grigg, the world-famed medical electrician of Eastbourne-terrace—who has been in practice for nearly 50 years—many years ago invented and patented an electromagnetic machine which gives a beautiful and steady current without any shocks. By its aid he has been able to cure not only paralysis, but also diabetes, Bright's disease, typhoid fever, and all the worst cases of disease which had baffled the skill of the most eminent medical men.

Mr. Herford, the coroner for Manchester, in his letter to you of 24th August, 1888, says: "I could say much of my well-known (almost perfect) cure from complete prostration by paralysis, and of cures similarly effected from varied ailments amongst my friends. You will, perhaps, permit me to mention, from my own knowledge, what seems almost a miraculous case of a gentleman suffering three or four years ago from chronic rheumatic gout, progressive paralysis, enervation, etc. He was entirely helpless—hands and fingers drawn out of shape, legs and feet powerless. His physicians said his case was utterly hopeless; but his friends applied to Mr. Grigg, by whom he was treated twice a day for nine months, and recovered perfect use of his limbs and powers. He was married soon after, and has now a son and heir."

Mr. Thomas Helsby, an eminent writer, who has a practical knowledge of, and has written on, the subject, observes that "Mr. Grigg's patented machines are the best yet invented for medical purposes, and that he is the only man living who knows the proper and scientific mode of application for the cure of all diseases."

Mr. Grigg ridicules the idea of attempting to apply electricity successfully to the relief of paralysis in the way indicated in your note, and says, according to his experience, that either drugs or stimulants in any shape or form retard (in place of facilitate) the cure of diseases.—Yours, etc.,

DAVID RODAN.

STEAM ENGINE ECONOMY.

SIR,—In reply to Messrs. Parsons's letter in your last week's issue, we are sorry to think that the figures upon which Mr. Willans based his remarks and his diagrams in the discussion on Mr. Crompton's paper should have been thought to be in any sense record figures. So far from this being the case, they were obtained from an engine which had not run very many hours. The rings had not, therefore, had time to come up to a face, and the engine was certainly not in a state to give the best possible results. It was a triple engine made for non-condensing work also, as all our engines have been up to now, and the best results could not be obtained from it when working condensing; moreover, in plotting the diagrams illustrating Mr. Willans's remarks, an efficiency $\left(\frac{\text{E.H.P.}}{\text{I.H.P.}}\right)$ of 80 per cent. only was taken, as he stated at the time. This is less than we often reach with new engines, and is certainly less than is usually reached after a few weeks' work with direct-current dynamos, working under the conditions which are present in electric lighting stations in this country.

At the low loads it was assumed that there were no reducing losses, which, even with the best dynamos, is not, strictly speaking, the case. The mean admission pressure in the cylinder at the highest observation taken in the condensing trial curve was 132lb. We have not a note of the pressure in the steam-chest, but it would be probably some 5lb. or 6lb. higher. The figures were used for the purpose of illustrating Mr. Willans's straight-line diagram, and in order to show (as was stated in his remarks) the gain which could be obtained, especially at light loads, even in the case of the very best possible non-condensing engine, by the use of a condenser. They were not intended in the case of the condensing trials to show by any means the best result obtainable. An engine which is to be used both condensing and non-condensing is at best a compromise.

The steam used in the trials was not tested at the time, but it probably contained 1 per cent. of moisture at the high loads, and was almost certainly dry, or even slightly superheated, at the lightest loads on account of throttling. The steam was taken through a separator in the ordinary way, but our trial boiler gives steam with about 2 per cent. of moisture in it, and this is not entirely removed by the separator so far as we have been able to ascertain.

Prof. Ewing did not give in his report the source from which he obtained the figures quoted. The figure 18·6lb. has been several times almost exactly obtained by us, and we did not know, until he mentioned the matter to Mr. Willans, that he was quoting from the *Proceedings* of the Institution of Civil Engineers. We should not have named that figure as an exceptionally good one, as we expect to do better.

In conclusion, we must heartily congratulate Messrs. Parsons on the results that they have obtained; we should not have written to the papers at all if these results had not been compared with our own.

Although we are quite sure that neither Messrs. Parsons nor Prof. Ewing had the least intention of saying anything which was not perfectly fair to us, there are many people who might make use of their report in a different manner if we had not written as we did.

The method, we believe, adopted by Messrs. Parsons of varying the power of the engine by admitting steam intermittently is a most interesting one, and, so far as we know, it is the first time that it has been applied to a steam engine. Undoubtedly, this method of reducing the power should tend in the direction of economy.—Yours, etc.,

WILLANS AND ROBINSON, LIMITED,
(C. S. Essex, Secretary),

Thames Ditton, Jan. 26, 1892.

PARSONS STEAM TURBINE.

The following letter from Principal Garnett, of the Durham College of Science, Newcastle-upon-Tyne, dated 25th January, 1892, addressed to Prof. Ewing, F.R.S., of Cambridge, has been forwarded to us for publication:

"My dear Ewing,—My attention has been called to some questions which have been raised respecting the effect of retardation of currents phase upon the output of the steam turbine, which you tested in Newcastle a few weeks ago. To determine the magnitude of the error thus caused, two sets of experiments were made, the former by Mr. Parsons and Mr. Stoney, the latter by Mr. Stoney and myself. In these experiments the coils used by you were compared with the water in a section of the cooling pond. The 1,000-volt armature was used, and iron pipes were thrust into the cooling pond to serve as electrodes, so that in comparison with the 1,000 volts the E.M.F. due to electrolysis was quite negligible, as was also any change of phase which it could produce.

"In order to secure the same number of true watts as the output of the alternator, the valve which gives the intermittent steam admission was blocked open and the steam was throttled by hand. In the second set of experiments the steam pressure at the point of admission to the cylinder was kept constant at 62lb., and the resistance was so arranged as to keep the volts the same with the coils as with the water resistance. A variation of pressure of 1lb. corresponds to about 1½ units per hour in the output. The volts being the same, and the resistance of the armature practically negligible, it follows that the speed must have been the same, and the speed and steam pressure being the same, its steam consumption, and therefore the output, must have been the same, unless the steam had the intelligence to know what was going on in the external circuit and the perversity to modify its conduct for the purpose of leading us astray. The result of this test was that with the same speed and the same steam pressure the product of Siemens and Cardew gave 49·5 for the water and 52 for the iron, showing an error of 5 per cent. due to the lag in the iron.

"In the other set of experiments the volts were kept the same, but the steam pressure as well as the amperes were allowed to vary, two sets of observations being made upon the coils, one with a greater and the other with a less output than in the case of the water. Repeated observations of the relation between the steam pressure and the load have enabled the law of variation of the one with the other to be accurately known, and it was therefore easy to interpolate between the two observations with the coils and to determine the apparent watts which would have been registered with the coils at the pressure used in the water experiment. The result of this interpolation showed that the product of Siemens and Cardew was 4·7 per cent. greater than the true watts.

"I hope that before long it will be possible to make a test of the turbine at the full working pressure of 140lb., and with a boiler of sufficient capacity to give fairly dry steam at full load. It was scarcely fair to the turbine to remove its high-pressure rings.—Very sincerely yours,

"(Signed) WM. GARNETT.

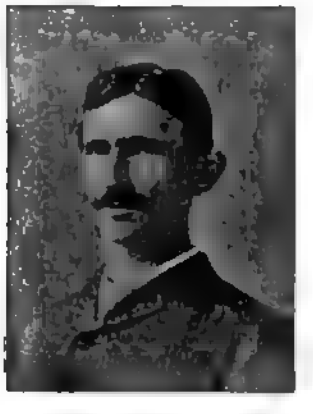
"To Prof. J. A. Ewing, M.A., F.R.S., etc."

MR. TESLA AND ROTARY CURRENTS.

Mr. Nikola Tesla is now in London, and electrical engineers will be pleased to learn is busy preparing his paper and his apparatus for the promised lecture to the Institution of Electrical Engineers upon alternating currents. This will appropriately take place at the Royal Institution, Albemarle-street, on Wednesday next, by the kind permission of the governors of the celebrated institution which the world-famous experiments of Faraday have rendered such classic ground to all scientific men. The occasion cannot but mark an important era in both theoretical and practical science, for the continuous attention, the experimental skill, and the keen insight of Mr. Tesla into the hitherto little explored ground of rapidly-alternating currents of high potential, with the astonishing results in demonstrating the possibility of lighting incandescent lamps without wires, have raised the expectations of scientific men to a high pitch. Mr. Tesla may well feel a little nervousness in coming before the scientific world in the capacity of apostle of a new and unexplored field, arising out of those opened up by Faraday's immortal experiments themselves; but the extreme beauty of the research, the importance, and apparently unlimited scope of the new experiments fitly carry forward the applications of electrical science whose basis was laid so thoroughly by Faraday in 1831.

For the moment, however, we will leave the fascinating question of high-potential electric illumination, and turn to that field in which Mr. Tesla has done, if possible, even more important work—that of the rotary current. The question of rotary current has taken a very different position in the eyes of English electrical engineers during the past year, due, to a very considerable extent, to the experiment on such a large scale at the recent Frankfort Exhibition, where the transmission of several hundred horse-power over a distance of 110 miles very forcibly brought the attention of the whole world to the importance of the rotary current. Before this time the knowledge upon the question was exceedingly vague, and, curiously enough, a long battle has raged around the very discovery of the rotary magnetic field and the rotary-current motor at a time when, in reality, there seems to have been not even a shadow of a doubt that the credit of the discovery and practical application of the system belonged to Mr. Tesla, who years ago had both patented and shown in working actual motors of the descriptions since shown in various other parts of the world.

The return of Mr. Tesla to Europe, together with the fuller details of his work, which will now be before us, will serve to create an entire revolution in the minds of a great many of those who are at present occupied, tentatively or practically, with this absorbingly interesting problem, and will put the whole question upon its proper basis. Until the publication in our columns a few months ago (September 11th, 1891, p. 246) of details and dates which were authoritatively given in America upon Mr. Tesla's experiments, the European electrical world was in doubt upon the whole question, or more probably gave the credit of the first discovery to Prof. Ferraris—whose work in this field certainly deserves the highest recognition—and the credit of the construction of the rotary-current motor, either singly or conjointly, to Herr Dobrowolsky, Herr Haselwander, or others.



NIKOLA TESLA.

It may be well to recall the dates given in the article above-mentioned. Prof. Ferraris's paper was given in March, 1888, and published shortly afterwards. Five months before this Mr. Tesla had filed his patents, and motors were run experimentally. On May 1, 1888, the patents were issued, and in the same month these motors were shown before the American Institute of Electrical Engineers, while it was not till May 18th that the work of Prof. Ferraris was published in England. As mentioned in our article on July 31st, 1891, it appears that Haselwander's rotary-current dynamo was constructed in the summer of 1889, and first set to work on 12th October of the same year; on July, 21, 1888, Haselwander applied for his German patents, which were accepted in 1890, and issued in June, 1890. Prof. Ferraris's experiments were undertaken in 1885, but Mr. Tesla claims to have been earlier afield. It seems, however, perfectly clear that men in widely separate localities were working independently, though contemporaneously, in the same direction and for similar objects.

On hearing that Mr. Tesla had arrived in London, we thought it well to take an early opportunity of calling upon him to obtain from him some particulars of the progress of the application of the rotary current in America, and to hear his views upon the question.

In the first place, it is interesting to learn that Mr. Tesla's discovery was due originally, not to direct experiment, but to abstract reasoning and mathematical calculation. A native of Montenegro, Mr. Tesla later came to Paris, and in the course of his lectures and study

was more particularly interested in the fascinating study of mathematical maxima and minima. Watching the action of the reversed dynamo running as a motor with segmented commutator, he suggested the desirability and the possibility of constructing a motor without commutator, which suggestion was scouted at the time. The march of his ideas, however, may be gauged from the mention of the maxima and minima theorem. Granted a rising and falling of E.M.F. in the commutator of a dynamo due to revolving position of the coils as now run, it was easy to jump to the conclusion that if waxing and waning currents could be sent into the coils in proper order, rotation should be at once obtained. Mr. Tesla is one of those gifted men who have that remarkable property, present in all men of high talent or genius, of an extraordinarily strong imaginative or conceptive faculty, by which material combinations are represented in the mind before they are constructed either on paper or in material substances. His motor was constructed and the results deliberately worked out in his mind before ever experiments were made; and he knew absolutely both that his motor would run, and which way it would run upon joining up the wires, and the result accrued exactly as expected. Unable to obtain sufficient

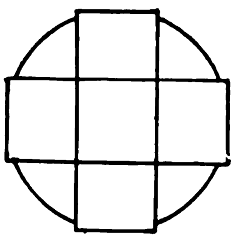


Fig. 1

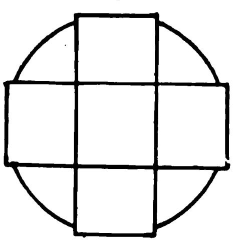

Fig 2

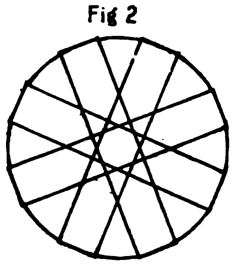

Fig 3

support in Europe, Mr. Tesla went to America, and there constructed and patented his motors. He constructed motors with the simple two-phase mentioned by Ferraris, in which the armature is wound at right angles, as indicated in Fig. 1. He constructed the three-phase motor since rendered famous as "Drehstrom" in Germany, in which the coils are distributed at an angle of 180deg. round the armature, as indicated in Fig. 2. He, further, long and exhaustively experimented with multiphase currents, both with split coils and with numerous separate currents, up to a dozen or more currents. The split multiphase current indicated in Fig. 3 is a simple modification of Fig. 2, by merely winding the three coils each in two coils disposed at a little distance from each other, thus producing a multiphase field; and he arrived conclusively at this result, that for practical purposes there is little to be gained in efficiency from the use of greatly-divided fields—not more, he finds, than of the nature of ½ per cent. gain. Motors were constructed, tested, and shown at the dates already mentioned, with efficiencies of over 90 per cent., and of great capacity for the weight—for instance, a 10-h.p. motor of 90 per cent. efficiency weighing only 850lb., half the weight of any of the same power since constructed in Europe. Results so promising, not to say revolutionary, could not but receive support, but his financial partners advised against publication of the full details and results, or European engineers would have long been in possession of the facts of the case. Mr Tesla's inventions, after being broadly protected in America, England, and Germany, amongst other countries, were taken up by Mr. Westinghouse, who proposed at once to put down large works capable of turning out 1,000 motors a week. Unfortunately, just at this moment occurred the financial panic which, it will be remembered, was suffered by the Westinghouse companies, and the matter had to be left. However, this has now been got over, and the motors are being made, and applied as fast as made. Mr. Tesla informs us—a fact that will astonish European electrical engineers considerably—that before he left he had seen running a 1,000 h.p. Tesla alternate-current motor, one of a number now being constructed at the Westinghouse Works in Pittsburgh for transmission of power. These are motors with revolving armature and three collector rings. Large numbers of the smaller motors have been in application for some time principally for mining purposes at high efficiencies and without needing repair. These motors start under load with strong torque: as an illustration, one experiment, with a small motor, was tried with a fixed rope over a 12in. pulley on the axle of the motor—the rope being previously tested to withstand 1,000lb. pull. On starting from rest the rope snapped immediately—a tangible demonstration of the strength of torque. Mr. Tesla states that his system of winding the alternate-current motors has now been brought to such a state of perfection, that for a three-wire circuit he can guarantee to build motors of large size to give 1 h.p. for every 20lb. of weight of an efficiency of 97½ per cent. What result better than this could be desired it is certainly difficult to imagine. It is evident, as we have said, that Mr. Tesla's appearance upon the scene will change the attitude of scientific men and engineers very considerably, both as regards the utilisation of rotary-current motors and as to the credit which should be given to this most interesting discovery.

INSTITUTION OF ELECTRICAL ENGINEERS.*

INAUGURAL ADDRESS OF PROF. W. E. AYRTON, F.R.S., PRESIDENT, ON ELECTROTECHNICS.

I beg to thank you for the great honour you have done me in electing me your president for this year—a year which the need for a new complete index of this Society's *Journal* marks out as closing the second decade of its life; a year which sees the second thousand added to our roll of members; and a year which the Electrical Exhibition at the Crystal Palace distinguishes as inaugurating the second decade of electric lighting in Great Britain.

It has gradually become the custom for your incoming president to select as the subject of his address some investigation that has been engaging his attention. Following this custom, I purpose to-night to discuss an experiment in which for the last 19 years I have taken some part—an experiment which of all others has been the one I have had most at heart—and that is, how best to train the young electrical engineer. To some it may appear that I am treading on well-worn ground; but as the problem is one that is as yet by no means solved, and as it involves the preparation of the machine that is daily used alike by the dynamo constructor, the cable manufacturer, the central station engineer, and the lamp maker—viz., the human machine—the problem of fashioning this tool, so that it may possess sharpness, an even temper, moral strength, and a mental grain capable of taking a high polish, is one that in truth deeply concerns every member, every associate, every student of this society. It is only 15 years ago since I wrote from Japan to my old and valued master Dr. Hirst, then the principal of the Royal Naval College, Greenwich, asking whether he thought that the time had come for starting in this country a course of applied physics somewhat on the lines of that given at the Imperial College of Engineering in Japan. He replied that England was not yet ripe for such an innovation—an opinion which appeared to be borne out by the fact that after the authorities at University College, London, had in 1878 actually advertised for applications for a new chair of "Technology," they decided that it would be premature to take the responsibility of creating such a professorship. But matters were advancing more rapidly than was imagined by collegiate bodies, for in that same year this most valuable report on technical education which I hold in my hand was issued by a committee of the Livery Companies of London, based on the opinions expressed by Sir W. (now Lord) Armstrong, Mr. G. C. T. Bartley, Colonel (now General) Donelly, Captain (now Sir Douglas) Galton, Prof. Huxley,

* Delivered on Thursday evening, January 28th.

and Mr. (now Sir H. Trueman) Wood. And although it is 12 years since this book was published, I can recommend it to your notice, for it supp ies most interesting reading even at the present day.

Under the guidance of the three joint honorary secretaries, Mr. John Watney, Mr. Sawyer, and Mr. (now Sir Owen) Roberts, the City and Guilds of London Institute for the Advancement of Technical Education started with a name that was very long, but in a way that was very modest, to develop a "trades school" in accordance with this report. They borrowed some rooms, but for use in the evening only, from the Middle-Class Schools in Cowper-street, Finsbury, and decided to erect ultimately a chemical laboratory in that neighbourhood. But neither the building of a physical nor even of a mechanical laboratory formed any part of the scheme for this "local trades school." For at that time the teaching of the practical applications of physics to industry hardly existed, and certainly not its application to any electrical industry other than telegraphy. To make a start, however, in such teaching was most desirable, and therefore Dr. Wormell, the enlightened head master of the Cowper-street Schools, consented to give up the use of some rooms not merely during the evening, but also during the day, to enable Dr. Armstrong and myself to carry out our plan of fitting up students' laboratories with a small amount of apparatus kept permanently ready in position. For the devotion of these rooms to the carrying out of this new experiment we must always feel grateful to Dr. Wormell, for it was necessarily accompanied by a reduction in the size of his school, and consequently by a pecuniary loss to himself. The first laboratory course of the City and Guilds Institute was then advertised, and on January 9, 1880, three students presented themselves—a little boy, a grey-haired lame man, and a middle-aged workman with emphatic but hazy notions about the electric fluid.

In order to further utilise these rooms the institute sanctioned laboratory teaching during the day, and one of the cellars of the Cowper-street Schools was borrowed in 1880 in order to fit up a gas engine, coned shafting, and a transmission dynamometer, obtained out of the funds of the institute; an A Gramme dynamo, lent by Mr. Sennett, then one of the students; and two arc-light dynamos for transmission of power experiments, lent by the Anglo-American Brush Corporation, whose cordial interest in the work of the City and Guilds Institute has been marked throughout. And as these dynamos were used, not for electric lighting, but as laboratory instruments for educational purposes, England can claim to have been one of the first in the field of teaching electro-technics. Rapidly grew these electro-technical classes; soon the temporary laboratories in Cowper-street were overcrowded, especially as applied mathematics and mechanics, under Prof. Perry, were added to the subjects taught; the £3,000 which had been set aside for the building of this "local trades school" grew into £35,000, thanks to the combined donations of the Drapers' Company and of the institute, and in 1881 was laid the foundation-stone of the present Finsbury College. During the many years that Prof. Perry and I were linked together, the work of either was the work of both; but now I wish to take this opportunity of acknowledging my personal debt of gratitude for the fund of suggestion which he put forth regarding the teaching of science through its practical applications—the keynote of true technical education. The value of these suggestions you will fully appreciate, for they form the basis of those characteristic and attractive lectures familiar to so many of you who have been his pupils.

As we have seen, then, the present Finsbury College grew out of the "local trades school," and formed no part of the original scheme of the institute. And it was because London was really in want of practical laboratory teaching about dynamos, motors, electric lamps, and engines, and because that want was supplied in a form suitable to the comprehension and to the pockets of workmen in the basement and cellars of the Cowper-street Schools, and last, but by no means least, because one of the executive committee of the institute, Mr. Robins, strenuously exerted himself to further technical education in Finsbury, that the various electrical, physical, and mechanical laboratories now in Leonard-street, Finsbury, came into existence. But the establishment of a central technical institution "for training technical teachers, and providing instruction for advanced students in applied art and science," had been recommended in all the reports sent in to the committee of the Livery Companies by the six authorities to whom I have referred. So that in the same year that the foundation-stone of the Finsbury College was laid by the late Duke of Albany that of the Central Technical Institution was laid by the Prince of Wales. And, if you will allow me to say so, the success of the latter institution has been no less marked than that of the former, for, in spite of the rather stiff entrance examination, the number of students who attend all four of the departments at the Central Institution is more than threefold what it was five years ago. In fact, in the mechanical and electrical engineering departments there are already about as many students under instruction as classroom and laboratory accommodation will admit. Hence this year will see a considerable increase in the amount of apparatus and machinery, as well as in the space devoted to dynamos and motors, in Exhibition-road.

While, on the one hand, the rapid growth of the work of the Guilds Institute is no little due to the fact that the latter end of this century has ushered in the electric age of the world; the electrical industry of our country, on the other hand, is no little indebted to the aid so generously given by our City companies to the teaching of electrotechnics. For the students who during the last 11 years have, for an almost nominal fee, worked in the electrical laboratories at Cowper-street, at the Finsbury College, and at the Central Institution, number several thousands, and nearly every electrical works, every place giving electro-technical instruction throughout this country, employs some of them. The success which these students have thus achieved through their own ability and exertions is, I think, in no small measure due to the institute having so wisely left the teaching it gave untrammelled by any outside examining body, so that it was possible for this teaching to be directed solely to the professional needs of the students, and to be modified from time to time as it seemed necessary. My hearty thanks are indeed due to the Japanese Government and the City and Guilds Institute, my masters during the last 19 years, for having left my colleagues and myself unfettered liberty to carry on this experiment of finding out better and better ways of teaching the applications of science to industry. And there need be no fear that with this freedom the teaching will become stereotyped, and gradually cease to deal with the living science of the factory, for being bound by no code we are able to vary our methods, our experiments, and our apparatus according to the continually-changing conditions of the profession. In order that the Guilds Institute should fulfil its aim, it is absolutely necessary that its teaching should keep pace with industrial progress. Now, even if it were possible for outside examiners, with fixed scholastic notions, to aid in securing this result, would not their efforts be superfluous, for are there not you, the employers of labour, to ultimately decide whether the human tool we fashion is, or is not, adapted to your requirements?

Leaving now the consideration of the direct work of the City and Guilds Institute, including their extended system of technological examinations, at which last year 7,322 candidates were examined in 53 different subjects at 245 different places in Great Britain and the Colonies, the indirect results that have proceeded from the initiative of this institute are even greater. For while 12 years ago education in applied science in this country was a tender little infant, requiring much watching and support, combined with constant encouragement, to-day Technical Education—with a capital T and a capital E, bear in mind—is a stalwart athlete, the strong man on the political platform, exercising the minds of county councillors, and actually regarded as of more importance than the vested interests of the publican. Until quite recently it was the technical education of the young engineer that had to be considered, but now the problem has become a far wider one, for the education of the British workman is being vigorously pushed forward, and I think that it has become incumbent on you—the representatives of the electrical profession—to express your decided opinion as to what this education of the electrical artisan ought to be. The technical education snowball set in motion 12 years ago by the City companies has been rolling—nay, bounding forward—so swiftly during the last year or two, that probably some of you have hardly followed it in its rapid growth both in size and speed. £30,000 has been spent on the Polytechnic in the Borough-road, the Charity Commissioners have already endowed this school with an income of £2,500 a year, and it is hoped that before the building is opened, this income will have been doubled. £50,000 has been already promised for the Battersea Polytechnic, the Charity Commissioners having also undertaken to provide this technical school with an income of £2,500 a year as soon as the subscription reaches £60,000; and for the establishment of a polytechnic in the City £50,000 has been set aside out of the funds of the Charity Commissioners, as well as a yearly grant of £5,350. Finally, not to speak of polytechnics in North, South, East, and West London, Mr. Quintin Hogg has himself spent £100,000 on the Regent-street Polytechnic; while the Drapers' Company have alone given £55,000 to the technical department of the People's Palace at Stepney, and endowed it with an income of £7,000 a year. And, most recently of all, the Goldsmiths' Company have put on one side nearly a quarter of a million sterling for the land, the buildings, and for an endowment of £5,000 a year in perpetuity, for their Technical and Recreative Institute recently opened at New Cross. The following table gives an idea of the sort of sums that are being spent on polytechnic education in London, but it does not profess to give the entire amounts that have been devoted to capital expenditure and yearly maintenance, even for the six polytechnics named in the table:

Capital Expenditure.		*Yearly Endowments.*	
POLYTECHNIC, BOROUGH-ROAD.			
Already spent........ ...	£30,000	Charity Commissioners alone	£2,500
		(Endowment expected to be doubled before opening.)	
BATTERSEA POLYTECHNIC.			
Already subscribed ...	£50,000	Charity Commissioners alone	£2,500
CITY POLYTECHNIC.			
Charity Commissioners alone to spend	£50,000	Charity Commissioners alone	£5,350
REGENT-STREET POLYTECHNIC.			
Spent by Mr. Quintin Hogg.....................	£100,000	Charity Commissioners alone	£3,500
Spent by Charity Commissioners	11,750		
PEOPLE'S PALACE, MILE END.			
Given by Drapers' Company alone	£55,000	Drapers' Company alone	£7,00
Given by Charity Commissioners alone	6,750	Charity Commissioners alone	3,500

TECHNICAL AND RECREATIVE INSTITUTE, NEW CROSS.

Given by Goldsmiths' Company	£70,000	Goldsmiths' Company..	£5,000
(Representing a total expenditure of nearly £250,000.)			
Other contributions to polytechnics in London by Charity Commissioners	£6,000	Yearly endowments of Charity Commissioners to other technical institutions in London	£3,200
TOTALS FROM THE ABOVE SOURCES ALONE :			
	£370,500		£32,500

Large as are these sums they are, however, even small compared with the amount raised by Mr. Goschen's beer and spirit tax, which it has been decided shall be used for the public benefit, and not for the benefit of the publican. The counties and county boroughs of England now receive nearly three-quarters of a million sterling per annum, of which the whole may be devoted to technical education. The majority of the counties and county boroughs propose to utilise this magnificent opportunity and devote to technical education the entire sum allocated to them, while the remainder use at least a part for this purpose. Middlesex and London, however, stand alone, and employ their whole yearly grant of £163,000 for the relief of the rates, on the plea that they consider that the City companies are well able to look after the technical education of London. Besides this spirit duty, 106 towns are levying rates in aid of technical education under the Technical Instruction Acts of 1889 and 1891, the number of these towns having increased by 20 in the last seven months, showing how rapidly is this desire for technical education spreading throughout Great Britain.

In addition to the sums contributed for technical education by the City companies, collegiate bodies, and private persons who have the practical education of the nation at heart, the following represent, as far as I have been able to ascertain, the amounts that it has been already decided shall be actually spent, yearly, on technical education in England alone, exclusive of Scotland, Ireland, and Wales:

Received from the Customs and Excise duties ...	£500,000
" " rates	18,046
Given by the Charity Commissioners	20,550
	£538,596

The yearly amount that will be actually raised under the Technical Instruction Acts will be far larger than the £18,046 stated above, for this represents only the sum of the amounts raised in the very few towns who have already made returns.

Hence the total sum to be spent in England alone on so-called technical education amounts to certainly over £600,000 per annum.

As the teaching of electrical technology has been started, in some form or other, in nearly every important town in Great Britain, there is no occasion for me to advocate, as I did in this room 10 years ago, that a student of electrical engineering should have an education in applied science; but what I desire to most strongly urge on you to-night is, that it is your bounden duty to see that some portion of the vast sum that is about to be spent on the education of the people is used to give such a training to your workmen as shall really benefit your industry. For otherwise there is a great fear that most of the money devoted to electrical teaching will either be frittered away on the natural loadstone, rubbed amber order of instruction so dear to the hearts of the schoolmen, or on semi-popular lectures describing in a bewildering, sketchy fashion the whole vast field of electrical engineering.

The workmen you employ are of two classes. In the one class is the man who is all day long, say, stamping out iron discs for armature cores, and the boy who, say, feeds the screw-making machine with its proper meals of brass rod. For such work no technical education is necessary; the workers are mere adjuncts to the machines, to be dispensed with as the machines become more and more perfect. Hence, unless the machine-minder has the ambition and the ability to rise to some less mechanical occupation, his activity, if any be left him after a hard day's work, had probably better be spent in effort of a lighter and more recreative character than would alone be necessary to make him a higher class of artisan. For him the polytechnic variety course of instruction is an inestimable blessing, for he can do a little typewriting, learn violin playing and modelling in clay, attend an ambulance class, recite a poem, and devote the remainder of his leisure to the piano botany, sanitary science, reading books and learning how to keep them. His general interests will be roused, the human side of his nature developed, and during the evening, at any rate, he may forget that he is the slave of the Gramme ring or the slave of the electric lamp. No wonder, then, that within two months of the opening of the Goldsmiths' Institute at New Cross 4,000 members were enrolled.

But your workmen of the other class must, or at any rate ought to, think. Take, for example, the man engaged in wiring houses, whose work is continually changing, and offering small problems to be solved. Here common sense, or uncommon sense, if you prefer it—is of great value, and the work, to be good, must be done by a man with a knowledge of principles, and not by a mere machine-minder. Many joints—bad joints—in wires laid in cement under mosaic, which cannot be replaced except at vast expense, even although the insulation has rotted away; parquetry floors nailed to insulated wire; switchboards screwed on to damp walls; lampholders that only make contact when the lamps are twisted askew; high-class insulated mains terminating in snake-like coils of flexible wire rubbing against metal in shop windows, under shop fronts; heavy Oriental metal lamps hanging from lightly-insulated cord; all this would be avoided, if the workman had been taught to use their brains as well as their hands.

Now, do you think that the teaching necessary for this purpose is likely to be given at the ordinary English polytechnic school? In the case of the Goldsmiths' Institute the electro-technical department has been put under the charge of Messrs. Dykes and Thornton, two diploma students of the Central Institution; and the fact that these men are, in addition, both employed in Messrs. Siemens's work at Charlton leads one to hope that their teaching, at any rate, will breathe the spirit of the factory. And, therefore, if ample funds be forthcoming for keeping the apparatus at New Cross always up to date, so that the motors, the models, the dynamos—not merely now at the start, but three years hence, six years hence—are truly representative of the industry, there will be a fair prospect that the electrical department of the Goldsmiths' Institute, although but a fraction of the whole undertaking, may really benefit the electrical workmen in the South-East of London. But my colleagues and I view with considerable apprehension the way in which the present wide demand for teachers in technical schools is being supplied. Several of our own students, for example, tempted by the comparatively high remuneration that is offered, have become teachers in technical schools immediately on leaving the Central Institution. In many respects they are undoubtedly well qualified; but if they had first spent some time in works before attempting to teach technical subjects they would have better understood the wants of the persons whom they have undertaken to instruct. No greater mistake can be made than to think that a student who has distinguished himself at a technical college can dispense with the training of the factory, unless it be the opposite mistake of imagining that the factory training is equivalent to, or even something better than that given at a modern school of engineering. It is the province of the manufacturer to turn out apparatus and machinery as cheaply, quickly, and as well made as is possible. It is the province of the technical teacher to prepare the human tool for subsequent grinding and polishing in the works. And this necessity for the teacher having himself passed through the shops has especial weight when we are dealing with the technical instruction of workmen, for in such a case there are three requirements absolutely necessary—first, knowing how to teach; second, possessing a fair knowledge of scientific principles; and thirdly—and this is perhaps the most important of all—knowing exactly what it is that the particular workman ought to learn in order to help him in his particular trade. Schoolmasters may have the first two requisites, and so may do valuable work in connection with the variety teaching at a polytechnic; but they are not in touch with the workshop, and therefore, no matter what may be their scholastic attainments, no matter what the extent of their experience in training the young, they are not the persons to give the real technical education to workmen.

In addition, then, to the polytechnics, we must have special schools for special industries, where workmen are taught the application of science to their special trades; and everything taught in such a school must be taught as bearing on the particular industry which the school is intended to benefit. A teacher of physics, for instance, must remember that he is not training physicists, but workmen whose use of physical principles will be bounded by their application to their special trade. For the great danger of such teachers is that, carried away with enthusiasm for their own subject, they will not subordinate it properly to the end in view—viz., helping the workman to know what will be useful to him in his work. Indeed, as Prof. Huxley pointed out in his original report to the Livery Companies' committee, "success in any form of practical life is not an affair of mere knowledge. Even in the learned professions, knowledge *per se* is of less consequence than people are apt to suppose. . . . A system of technical education may be so arranged as to help the scholar to use his intelligence, to acquire a fair store of elementary knowledge which shall be thorough as far as it goes, and to learn to employ his hands, while leaving him fresh, vigorous, and content; and such a system will render an invaluable service to all those who come under its influence. But if, on the other hand, education tends to the encouragement of bookishness, if it sets the goal of youthful ambition, not in knowing, but in being able to pass an examination, especially if it fosters the delusion that brain work is in itself a nobler or more respectable kind of occupation than handiwork, and leads to the sacrifice of health and strength in the pursuit of mere learning, then such a system may do incalculable harm, and lead to the rapid ruin of the industries it is intended to serve." And I venture to think that not merely at technical schools for workmen, but at technical colleges for engineers, it should be ever remembered that the main object of the training is not the cultivation of mental gymnastics, but to enable the student to acquire knowledge and habits which shall be professionally useful to him in after life.

"Useful learning usefully taught" would be no bad motto for technical institutions, seeing that those who favour the compulsory teaching of Greek are apparently willing to accept the converse as the motto for the university. For example, Mr. Butcher, in his address delivered at the end of last session at University College, Bangor, said, "We claim it as a distinction that in the seats of academic learning little or nothing useful is taught"; and in an article in last month's *Fortnightly Review*, congratulating Cambridge on its recent victory over the barbarian, Mr. Bury says, quite candidly, "Greek is useless, but its uselessness is the very strongest reason for its being a compulsory subject in the university course." And he add, in italics, "*For the true function of a university is the teaching of useless learning.*"

A few of the county councils have realised that the real teaching of the application of science to a special industry, which is what

the British workman is so much in need of, cannot be given, as well as a host of other subjects, out of limited funds. For example, Bedfordshire has decided to spend its grant of £4,343 mainly on agriculture, market gardening, the straw trade, domestic economy, and industries for women; Cambridgeshire and Cheshire devote themselves largely to the teaching of agricultural pursuits. But other places aim at issuing vast comprehensive programmes and turning out yearly a mighty array of students, knowing, it may be, the something of everything, but who certainly will not know the everything of something. For example, the Holland division of Lincolnshire has decided, out of only £2,000 a year, to make grants for daily schools, university extension and art schools, agricultural science, domestic economy, mechanics, commercial subjects, and ambulance teaching; while Bootle, with a yearly expenditure of only the same amount, maintains classes in five commercial subjects, in 16 science and art subjects, in cookery, wood-working tools, as well as four courses of university extension lectures. Because a certain building in Regent-street, famed for its ghost and its diving bell, was years ago named "The Polytechnic," the majority of the new technical institutions which are being established in London at such vast cost are also called "polytechnics," and will, I fear, give only an English polytechnic course. Now, such recreative education, although admirable for those who seek relief from work in the use of their minds, is not generally sufficient for those of your workmen who use their minds in their daily occupation.

It ought, then, to be thoroughly recognised that there is an entirely new problem to be solved, and that the solution of this problem, in so far as it has been worked out at the Finsbury College and at other places giving practical teaching in the evening, must, in the language of the mathematician, be regarded simply as "the singular solution," and not the general solution, of the problem of technically educating the British workman. Let us gratefully accept the English polytechnics, for they will undoubtedly confer benefit on our country, and all credit be to those who have so generously established them. But do not let us be misled by the similarity between their generic name and that of the German "polytechnicum" into fancying that the recreative courses of the one are equivalent to the serious education given by the other. Like Oliver Twist, let us ask for more, for, on behalf of the large number of minds already employed in the electrical industry, and on behalf of the still larger number that will in the future be so employed, it is our duty to secure that ample provision be made in this country for the practical teaching of electrotechnics on a scale comparable with that afforded in the technical high schools of Germany and the institutes of technology of the United States. On the screen you see projected a photograph of the façade of the Technical High School at Charlottenburg (Berlin), which appears extensive and grand; and yet, as you will see from the next photograph, it was only a small portion of the whole building that you were looking at on the first photograph. This is but one of the many technical high schools in different towns of Germany, and yet it covers an area more than five times as large as that occupied by the Central Technical Institution in Exhibition-road, London, cost four times as much to erect, and has more than four times as much spent on its yearly maintenance. The next photograph shows a building devoted wholly to the training of electrical engineers, being that of the Electro-Technical Institution Montefiore at Liège, which Prof. Gerard kindly took me over this last summer, and which has since been opened. When I tell you that there are rooms for small direct-current dynamos, separate rooms for large direct-current dynamos, separate rooms for alternators, and that every three students have a separate little laboratory, with the necessary measuring instruments, all to themselves, your educational mouth will water, as mine did.

We now cross the Atlantic to the Massachusetts Institute of Technology, Boston, which, as you see, consist of several distinct buildings, the centre one being that which contains the electrical laboratories. The dynamo-room, now seen on the screen, has many small and large dynamos in it, and yet there is ample room to walk about, for this dynamo-room occupies a space many times as large as that devoted to dynamos at the Central Technical Institution of London. Prof. Cross was so good as to mention in a letter that was shown me some two years ago, that several of the devices that had been worked out for the electrical laboratories of the City and Guilds Institute had been reproduced at Massachusetts; but there is one device that Prof. Cross has succeeded in working out, and which I should be most glad to see copied by the City and Guilds Institute, and that is, having one assistant for every five students working in the physical laboratories. Franklin Hall, presided over by Prof. Nichols, is devoted solely to the department of pure and applied physics at the Cornell University, Ithaca. You see how large this four-storeyed building must be, for look how small the four-wheeled waggon standing in front of it appears. The next three photographs show some of the provisions made for teaching electrotechnics in Franklin Hall; the electrical laboratory, under Prof. Moler; and the dynamo-room under Prof. Ryan, whose analysis of alternate-current curves are well known to you all. I might show you photographs of the electrical laboratories in Prof. Weber's new building for physics at Zurich, on which £100,000 has been already expended. In fact, my choice of magnificent continental and American laboratories has been so great that I have hardly known which to select as specimens. But there is one thing I cannot show you—and it must remain for the exercise of your influence as representatives of the electrical profession to make that possible—the British electro-technical laboratories for education and research which are truly worthy of London, the capital of the world.

The training of such students as those at the Central Institution must, of course, differ essentially from that of the electrical artisan, not because we or the students expect that on entering a factory at the conclusion of their college course they will start, as a rule, much above the bottom of the ladder, but because they hope in time to be able to mount higher. They are, therefore, taught not merely to construct meters and motors, use dynamos and engines, build a chimney and lay a street main, but, as they are not to spend all their lives wiring houses or watching a central station voltmeter, they are well practised in calculating and designing, and they further obtain sufficient acquaintance with the methods of attacking new problems not to be daunted when they meet with them in after life. But so strong is becoming our belief in the value of science to the manufacturer, so anti-classical are some of us growing, that there is great risk that the literary side of the education of an electrical engineer will soon be wholly neglected. Now, important as it no doubt is for him to be quite at home with electrical apparatus and machinery, it is no less important, if he is to take advantage quickly of the progress made abroad, that he should be able to read a German or a French newspaper. I do not merely mean that with a grammar and dictionary, and plenty of leisure, he should be able to translate the newspaper, sentence by sentence, like a schoolboy preparing to-morrow's lesson, but that he should have the power to glance down the columns, gather the gist of the articles, and quickly see whether there be anything new that especially concerns him. How many electricians are there in this country who can, for example, take up the *Zeitschrift für Instrumentenkunde* or the *Electrotechnische Zeitschrift* and look through their pages as they do those of the *Electrician*, the *Electrical Review*, and the *Electrical Engineer*, during breakfast on Friday morning. There are, I know, a few—I wish I were one of them. And yet examples are not wanting of the scientific isolation that is caused by not possessing that familiarity with foreign languages which is such a characteristic of diplomatists and hotel waiters. Take, for instance, the fact that whereas manganin was manufactured on a commercial scale in Germany, and German resistance coils have for the last three years been constructed of this material with a temperature coefficient of nearly zero, the very existence of this alloy was unknown to many English electrical instrument makers a few weeks ago; and even now many of them are still unacquainted with the composition of manganin, and its peculiar properties, as well as with the results of the extensive and striking experiments that have been carried out at the Reichsanstalt at Charlottenburg on the temperature coefficient and specific resistance of all sorts of manganin-copper-zinc-nickel-iron alloys. This Physikalisch-Technischen Reichsanstalt, I may mention, is an establishment totally distinct from the Technical High School in Charlottenburg, some photographs of which I showed you this evening. The Reichsanstalt is not an institution with students, but a vast series of Imperial laboratories, presided over by Prof. von Helmholtz, solely used for carrying out researches in pure and technical physics. The investigations are conducted under the direction of Dr. Loewenherz, aided by 46 assistants. We have no establishment in Great Britain at all comparable with this Reichsanstalt. The original work turned out there in electrotechnics alone is considerable. Here are some of the published accounts of researches immediately bearing on your profession which Dr. St. Lindeck has been so kind as to send me: "Hardening Steel Magnets," "Standard Resistance Coils for Large Currents," "Tests of Commercial Ammeters and Voltmeters," "Mercury Standard of Resistance," "Photometric Investigations," "Compensation Apparatus for Use in P.D. Measurements," "Alloys for Resistance Coils," and so on. Surely it is part of the technical education of the electrical engineer to be taught how to read such pamphlets as these with comparative ease.

A working knowledge of French and German can be obtained without the necessity of learning to express oneself fluently in epigrammatic French, or to imitate with facility the word-building of a native German; and with such a working knowledge the average technical student may rest content. But as regards his own language he should aim at something higher, and therefore the electrical engineering students of our country should be, I would urge, practised in writing—yes, and also speaking—vigorous English. Only the other day, Prof. Nichols, of the Cornell University, was deploring with me the rarity of finding a student of electrotechnics who could write a decent report. The experimental methods employed in the student's investigation might have been good, the mathematical analysis suitable, and the calculations exact; but the description of the apparatus and of the results obtained would be scattered pell-mell over the paper, as if the writer were quite ignorant of the fact that the style in which a dish is served up is nearly as important as the goodness of its ingredients. Why do you suppose that Huxley's portrait has nearly as much prominence given it in the photographer's window as that of a duke or a ballet dancer? Quite as much because he knows how to express himself in terse and forcible English as on account of his wide scientific knowledge; because even when writing about dry bones the flow of his language clothes them with rounded forms. But, you will ask, how are we to find the time for all this linguistic and literary polish? Has the electrical student of to-day so many spare hours that fresh subjects of study must be sought for to fill up his leisure moments? At present much time has to be wasted at technical and other colleges teaching students 16 years or older elementary mathematics and science, which ought to have been mastered before that age. When the education of childhood is improved, when the higher education of women is properly carried out, there will be no need for male experts to

trouble about general training, for then children will spend less time at school and learn more; boys and girls will as a matter of course acquire the foundation of modern languages and general education; and students at a college will be able to devote their whole time to the special training—scientific, manual, linguistic, and literary—which pertains to the particular profession which their special tastes will generally have led them to select before the age of 16.

And just as methods of teaching applied science have been developed during the past few years, so I look forward to the growth of new methods of teaching what may be called applied literature, for it seems to me that there is a want of breadth in the view that because the study of Greek verse would be unprofitable for a student of electrotechnics, and because he has neither the taste nor the time to enter into the intricacies of etymology and grammar, therefore the study of modern languages and literature, even as directly applicable to his profession, should form no part of his regular training. As well might it be thought (and I am sorry to say this view is not yet quite exploded) that because a student has neither the taste nor the time for the study of abstract mathematics, therefore he should be debarred from all work in a physical laboratory. Well, if it be generally accepted that although a young electrical engineer has no chance of becoming a Cayley or a Maxwell, still he ought to be taught such portions of mathematics and physics as will be directly useful to him in his profession, why should the certainty that he will neither become a Jebb nor a Dickens lead us to tolerate an inability on his part to speak fluently and write tersely his own language, surpassed only by his entire ignorance of every other? Habits of scientific thought are highly necessary for electrical students; to be masters of their own language, and to know something of one or two others, are, I venture to think, no less so; but the main result to be achieved, the main object to be aimed at, with every system of education, is moral thoroughness. For until every workman, foreman, engineer, and manufacturer feels regret and pain at seeing work inefficiently performed our national system of education will be incomplete. All the labour now expended in watching work in progress, and in testing it when completed to see that it has not been scamped, is so much withdrawn from the real business of production. Every rise, therefore, in the standard of thoroughness of a community means the saving of waste labour. But far greater than this will be the actual increase in the productive power when each gives his best endeavours to his share of the world's work. And greatest of all will be the gain in the nation's happiness, since he who works with his whole soul knows no drudgery. The lesson to be taught is no new one—it was set many centuries ago; and hundreds of thousands a year will be well spent if the county councils can succeed in bringing home to the hearts of us all this—"Whatsoever thy hand findeth to do, do it with thy might."

ELECTRO-HARMONIC SOCIETY.

A smoking concert will be held on Friday, February 5th, 1892, at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., at eight o'clock.

Artistes: Mr. Schartau's Part Singers, Mr. H. Schartau, Mr. E. Dalzell, Mr W. Bradford, Mr. C. T. Johnson; clarinet, Mr L. Beddome; violin, Mr. T. E. Gatehouse; solo pianist, Mr. Alfred E. Izard. Musical directors: Mr. T. E. Gatehouse and Mr. Alfred Izard. A Broadwood piano will be used. The following is the programme:

PART I.

Plantation Chorus .... "Dinah Doe" ....
Mr. Schartau's Part Singers.

Clarinet Solo .... "Adelaida" .... Beethoven.
Mr. Leonard Beddome.

Song .... "By the Fountain" .... Adams.
Mr. E. Dalzell.

(a) Part Song .... "The Soldier's Farewell" .... MS.
(b) Humorous Quartette... "The Franklyn's Dogge" .... Dr. A. C. Mackenzie.
Mr. Schartau's Part Singers.

Pianoforte Solo ...... "Variations Sérieuses" Op. 57, Mendelssohn.
Mr. Alfred Izard.

Plantation Melody........ "Poor old Joe"...... Specially arranged.
Mr. Schartau's Part Singers.

Humorous Song...... "The General Election" .... MS.
Mr. H. Schartau.

PART II.

Vocal Polka .... "Trip, Trip" .... German.
Mr. Schartau's Part Singers.

Clarionet Solo ...... "Lo! here the gentle lark" .... Bishop.
Mr. L. Beddome.

Song...................... "The Diver" .... Loder.
Mr. W. Bradford.

(a) Part Song .... "Spin, spin" .... Jungst.
(b) Humorous Part Song "The Boy and the Tack." .... MS.
Mr. Schartau's Part Singers.

Violin Solo .... { (a) "Largo" } .... Handel.
{ (b) "Saltarella" } .... Papini.
Mr. T. E. Gatehouse.

Song .... "The Pilgrim of Love." .... Bishop.
Mr. E. Dalzell.

Part Song .... "When Evening's Twilight" ....Hatton.
Mr. Schartau's Part Singers.

CARDIFF AND ELECTRIC LIGHTING.

The Cardiff authorities have been collecting information as to electric lighting in other towns, and a report upon the subject was before the Council at its last meeting. It appears that over 50 towns have taken no steps whatever in the matter of lighting by electricity. Of the 16 boroughs whose replies are detailed, Accrington, Bradford, Brighton, Cambridge, Dover, Glasgow, Hastings, Huddersfield, Hull, Manchester, Richmond (Surrey), Walsall, and Worcester, have obtained provisional electric lighting orders, that of Brighton, though obtained in 1883, not being put in force till 1890. Neither Bognor, Eastbourne, nor Leamington has obtained such orders. Bognor is to be supplied by the Electric Trust Company, whose order provides for supply of public lamps by agreement, for a charge of 13s. 4d. per quarter for any amount up to 20 units, and 8d. per unit over that number. Eastbourne parades are lit by the Eastbourne Electric Lighting Company, whose arc and incandescent lamps are placed 100 yards apart, the charge both for public and private supply being 10d. per unit. The light, it is said, gives every satisfaction, but it is admitted to be costlier than gas. At Leamington a private, and not a public, supply is provided by a private company at a charge of 8d. per unit. At Bradford the scheme is not in operation as far as regards street lighting. The erection of works cost £5,213; mains, £3,361; machinery, etc., £24,354; and boilers and fittings, £3,174, making a total of £36,102. The sum borrowed totalled £34,342, the period allowed for repayment being 30 years. The light is also not used for street illumination at Brighton, where the cost is estimated at £35,000, in addition to £2,500 for land. The system adopted is that of low-tension continuous current, supplemented by storage batteries. The charge is 7d. per Board of Trade unit, the same charge being made for the supply for motive purposes. Cambridge has just applied for power to borrow £35,000; whilst at Dover the powers obtained by the Corporation are about to be transferred to the Brush Company. No works have yet been constructed, and no streets are yet lighted at Glasgow, but it has been decided to adopt the system of low-tension continuous current, and Prof. Kennedy, of London, has been engaged to prepare a scheme for putting down the installation for lighting the compulsory area. The Hastings Corporation has contracted with a local company for lighting 15 lamps on the parade at £30 per lamp per annum. The Huddersfield Corporation has entered into a contract for the erection of plant, and are applying for power to borrow £50,000. The Lighting Committee of the Hull Corporation are only about to take the initiative. They do not intend to light the streets at present, but only to supply private customers. The sum of £22,000 has been granted by the Council. The system is the low-pressure continuous current, and the price 7d. per unit. At Manchester a consulting engineer has been appointed, a site for a central station obtained, and plans and specifications are now being prepared. Richmond has entered into a contract with a company who have laid the wires. At Walsall a committee has reported in favour of carrying out the provisional order at once, at a total estimated cost of £21,450. The system has not yet been settled. The Worcester Corporation is also about to establish the necessary works to put their provisional order into force, and at the beginning of this month advertised for tenders for constructing works for the central portion of the city. These tenders are to be in by February 14.

COMPANIES' MEETINGS.

ST. JAMES'S AND PALL MALL ELECTRIC LIGHT COMPANY.

The annual ordinary meeting of this Company was held at the St. James's Hall Restaurant, Piccadilly, W., on Tuesday afternoon, 26th inst., the chairman, Mr. Eustace J. A. Balfour, presiding.

The **Secretary**, Mr. F. J. Walker, having read the notice convening the meeting, and the Directors' report having been taken as read,

The **Chairman** said: The next business of the meeting is the proposal that the report and accounts for the year ending December 31st, 1891, as submitted by the Directors, be received and adopted, and that the dividends recommended therein be declared and paid on the 1st February.

This was seconded by **Mr. Latimer Clark.**

The **Chairman** then said: I don't think it is very necessary for me to go to any great detail into the working of the Company during the past year, because the report is very full, and I think on the whole gives such information as it is desirable should be placed in the hands of the public. Perhaps the most important event of the year was the raising of the £100,000 of additional capital in the form of preference shares for the completion of the northern station. The last £50,000 of this was largely oversubscribed at a premium of 30s., a fact which, I think, indicates that both the shareholders and the public in general show great confidence in the soundness of the business of the Company. This sum of £100,000 will, as you are aware, be chiefly, and has been partly, devoted to the purchase of the site for, and the erection of, our northern station. We expect this station when erected to be probably the best of its kind in the world, as it will

contain all the accumulated experience that we have gained in the erection of our present station, as well as that which other companies have gained in similar work. The machinery sufficient to furnish about 20,000 8-c.p. lamps is already nearly completed for that station, and will be placed in position as soon as the building is ready to receive it. It may be of interest to the shareholders to know that a large part of this machinery was running and supplying light at the Naval Exhibition, and that we have therefore this advantage in purchasing it—I may say it was purchased before it went there, and belonged to us while it was there—it has been running for this time without hitch or flaw, and we took it over, not as new experimental material, but as having been actually tried and found entirely satisfactory. A great feature in the system which we are now developing is what we call the great trunk main, which is already partially made, and which will connect the northern station with the existing station in Mason's-yard. It has a section of eight square inches, and is probably the largest main ever made. It is capable of carrying a current sufficient to supply 25,000 lamps. The importance of this cannot be over-estimated, because, well as our present station has worked up to the present time, and well as we expect it to work, it is impossible to suppose that it will not or may not be necessary to carry out repairs in it which may involve its being shut down for a short time. When this main has been constructed, and when the northern station is in working order, we shall be in a position during the slack months of the year to shut down either one station or the other for any repairs that may be desirable, and to work entirely from the one that is not shut down, and that without any alteration in the supply of the light in the consumers' houses. An eminent electrician connected with electric lighting told me some months ago that he thought that all new electric light stations should be built with two chimney shafts. Whether he is right or not in his opinion I do not venture to say, but the system that we propose to adopt combines all the conditions of his proposal and a number of others besides, in addition to being much more economical. I don't think I need add anything more on the particular subject of the working of the Company during the past year, but I should like before I sit down to touch upon a matter which I regard as of very great importance, not only to this Company but to all electric lighting companies, and to the whole question of the electric lighting of the Metropolis—I refer to the legislation under which we have obtained our provisional order. When legislation was first of all started with respect to electric lighting, in the year 1882, the term fixed for the expiry of a license was seven years. That is to say, licenses could be terminated by a local authority or the Board of Trade in seven years. This legislation seems to have been passed under a sort of morbid terror that electric light companies were going to become enormous corporations with great powers of monopoly. A provisional order under the same Act was limited to 21 years. The result of this extraordinary Act was that everybody who had invested their money in electric lighting concerns, lost it, and that the public was kept out of electric lighting for several years, London thereby becoming far behind any other capital in Europe in this matter, and far behind many towns and villages in the west of America. Under the present Act we have our provisional order lasting for 42 years, but that provisional order, and all provisional orders, are subject to two conditions: Firstly, that the Board of Trade can revise rates at the end of every seven years. That is to say, the Board of Trade can step in and say to us, "You are charging too much" at the end of every seven years of our tenure beginning from 1889; and secondly, that the Board of Trade has arranged to put into every parish, or district, or area in London at least two electric light companies. Now, if you will consider these points for a moment, I think you will see that they act first of all against the consumer indirectly, and also against the electric light companies. As we have only a terminable lease of life of 42 years, it is absolutely necessary for us to put by what we have termed a redemption fund, calculated to be sufficient to replace the deficit in the capital account, which we anticipate at the end of 42 years, when we shall or may be obliged to hand over our business at a valuation to the local authority, which has the option of purchasing. If our tenure were permanent, after paying to our shareholders a reasonable dividend, we could use the amount of this redemption fund in reducing the cost of the light. In the present year, I think, making a rough calculation, I may say that even if we paid to our present shareholders the same dividend as we propose to pay, we should have been able to reduce the cost of the light to the consumers about one penny out of every seven. Consequently, the power of septennial revision introduces an element of uncertainty into the business, which must be injurious to all the interests concerned. Nor is it likely that this revision can be made to work in a practical manner. Had the Board of Trade seen fit to grant complete monopolies in every district—that is, one company in every district—subject to some scheme of revision on a previously defined sliding scale, such a system might, I think, have been found to work. But as it is, on what basis are they going to revise? Supposing we have a case in one district, say a London parish, of two companies, one of which has paid on an average for the seven years a dividend of 20 per cent., and the other during the same period a dividend of 2 per cent. Is the Board of Trade going to insist upon the reduction of the cost of electric lighting because one company is paying and the other is not? In that case you might find the shareholders of the company that had paid a small dividend absolutely ruined. In fact, they (the Board of Trade) cannot get out of this, they will either be hard or unfair upon one of the companies, or upon the consumers in the district. In fact, I may say with respect to this, it is quite clear that the two systems which they have adopted of what they term limited competition and of revision of rates, are absolutely inconsistent. Now, lastly, the system of limited competition is injurious alike to consumer and producer, in that it makes it necessary to earn a dividend on a much larger capital than would be necessary to supply a district. Supposing you have two electric light stations and two sets of mains in one district, instead of one. The amount supplied in the district is the same, but the dividends have to be earned on a capital which, I think, I am not overstating to be at least half as much again as is required. You have, in addition to that, the disadvantage that the streets are pulled up twice for every time they ought to be, and you have also to consider that the initial expenses of a company have to be twice incurred, and these, gentlemen, are items which are very much larger than those who are not in the middle of the business are apt to think. I have no more to say, but I hope that if shareholders have any remarks to make or questions to put they will kindly do so.

Colonel Francis said he had some remarks to make as to the accounts, and some questions to ask, which he considered he was entitled to have answered in his own interest, and in that of large shareholders who had become interested in the Company on his recommendation. As to that paragraph of the report in which the net earnings of the Company during the past year were stated to be £10,395, he said that the net earnings of the Company for that period had been £15,409, and that part of the law charges item, £558, which included any expenses incurred in 1890, ought not to come out of the revenue of 1891. He had added to the net earnings, as stated in the paragraph, the total amount of the depreciation and redemption funds. His reason being as follows: He found that the very large sum of £1,702 had been charged during the year to the repair of machinery. When he was a director of the Company he consulted the makers of the machinery, and they informed him that if it were kept in perfect repair the depreciation was very slight. He (the speaker) held that a sum of 5 per cent. on the whole of the machinery would be ample for the purpose of depreciation. At all events he asked on what calculations the enormous sum of £4,013 (depreciation on buildings and machinery) had been worked out, if the sum of £1,702 had been spent on repairs? Had the original articles of association remained in force and not been altered, it would have been impossible to introduce such a charge as the redemption fund. They would see by referring to them that a reserve fund could only be applied for purposes indicated by a resolution of the Company in general meeting. This was article 76, old form, which had now been cut adrift. The painful impression of last year still remained, he believed, in the minds of shareholders. It was represented to them in the concluding paragraph of the report for 1890 that, in order to obtain a quotation on the Stock Exchange, it was necessary to remodel the articles of association. It was then discovered that the omission of the words "not to exceed £1,500" placed the shareholders at the mercy of the Directors. He wished to know the grounds on which the Directors said that there would be loss of capital at the expiration of the term covered by the provisional order. He had compared Section A, revenue account (cost of generation and distribution of electricity), for 1890 and 1891. The difference was more than double. He thought there would be no reason for surprise at this if there had been a large increase in the items of coal and labour. But he found that the enormous increase in this matter of expenses was otherwise carried out, the coal and labour charges only counting for £3,200. Turning to the capital account, he found that the sum of £20,297 had been paid for the new site of the northern station. They would remember that Mason's-yard cost £9,500, and that a site within 50 yards of the present one was obtained while he was a director of the Company for £1,100 and £100 a year, in Canton-street, which was nearly as large and as suitable. He had had the present site (northern station) valued by the most experienced surveyor of the parish, and he placed its value at £8,000. The offices of the St. James's Company were small in size, and, so far as he had observed, plain in appearance. There were three small rooms. However, the Directors had managed to spend £715 on furniture. Machinery and plant were spoken of as costing £12,000. Was that machinery in the new station or had it been supplied for the original one? Could not the capital accounts of the two stations be kept separate, so that shareholders might know exactly what each one was to cost? Now as to the financial arrangements of the Company; £100,000 had been obtained from shareholders for preference shares, paying interest at 7 per cent. At the time that this was proposed there was considerable opposition to it, for it was perfectly well known that the money could have been raised at 5 per cent. In fact, an offer of £50,000 at that rate had been made to the Directors and was spoken of at the last meeting. However, it was urged that if the sum was large, at any rate the original shareholders would benefit by the transaction. The original debenture holders who had power to convert did benefit, and in his opinion this transaction was executed for their benefit. Of this amount, it appeared that £27,000 were on deposit at Messrs. Lloyd's bank. He would like to know at what interest? The £15,000 premium that had been obtained by the issue of the second lot of shares was placed at 2½ per cent. He thought it was absolutely necessary in any case that the shareholders should obtain information of what was going on more than once a year. £353 had been spent for printing and advertising. He might be unfortunate, but he had never seen any advertisement of the Company's in any paper. Neither he nor any other shareholder had received any communication as to what had been going

on in the Company since the last meeting. They were in absolute ignorance, and remained in the Directors' hands. He did not think it ought to last. He would ask, upon what scale had the Directors gone in forming their estimates of depreciation on machinery and buildings? Had the whole of the sum of £558 become due for law charges in 1891? On what grounds did the Directors represent that there would be loss of capital at the expiration of the term covered by the general order? What course did the Directors intend to pursue in relation to their fees? Did they intend to replace the words "not to exceed £1,500" in the paragraph of the articles of association bearing on this matter? As printing was charged at the rate of £350 a year, would the Directors see that a full report of each meeting was sent to the shareholders? He thought those gentlemen who lived in the country and sent in proxies to the Directors, should have a fair and distinct report of that meeting. Would the Directors arrange that a meeting be held twice each year, in January and July? What amount was paid for the new site (of the northern station)? Who was the vendor? What surveyor acted on behalf of the Company, and recommended that sum to be paid? What sum was to be paid under the contract for building the new station? What sum would be spent on machinery? Could not the capital account of the two stations be kept separate? And then came the old question of the 18 founders' shares which were, as he firmly believed, most improperly and illegally handed over to the Debenture Corporation by its trustees? He had been to great expense about this matter, and had consulted counsel, who said all that he had got to do was to bring an action, and that no judge or jury could by any possibility sanction the proceeding. What did the Directors intend to do on that point?

Mr. Muirhead objected to their meeting in a public-house in the West-end instead of in the City, which would be much more convenient. He observed that it had deprived them of the attendance of two Directors (Mr. Kirby and Mr. Clarke). (It was explained that Mr. Kirby was detained in the Law Courts as a witness). He did not think the accounts were at all an exhibition of economy or management. He particularly pointed out the items for repairs and depreciation, and what he termed the "ridiculous" redemption fund. For this latter he could see no reason, because he presumed that Company was bound by Section 2 of the Electric Lighting Act of 1888. In that Act it was provided that should the property of the Company be taken over by the local authority the price to be paid was a fair market value at the time of purchase. He thought this value would be par at least. He observed that at compound interest the amount put by would rise beyond the requirements of the case—£95,000, he was understood to say. The law charges were preposterous. He thought the Chairman had taken an altogether pessimistic view, though he could quite understand that he did not want to make the best of the case, because the Board of Trade might be down on him. It was no use their knocking their heads against the Board of Trade; the Company were bound to conform with their requirements. It was to be regretted that they had the power to revise the Company's rates in seven years, but they would have to face that when it came. He didn't think the Board of Trade would be hoodwinked by accounts.

Mr. George Freeman thought their meetings ought to be held in the City, and that a verbatim report should be sent to the shareholders. He asked a question as to the interest on founders' shares, and the undivided profit account for founders' and ordinary shares.

Mr. Scrase wanted to know from the solicitor to whom the redemption fund would belong at the end of the concession—would it belong equally to founders and ordinary shares?

The **Chairman** said if there were no other questions he would go through those asked, as far as might be, *seriatim*. One or two of them, however, required a little reference to figures and the articles, so that he would have to consult his co-Directors as to the answers. First, on what scale was the estimate of depreciation formed? The matter was discussed with extreme care, and the scale adopted was the ordinary one in businesses of this character—viz., 1 per cent. on mains, 2½ per cent. on dynamos, general machinery, and plant; 10 per cent. on accumulators, etc.; 15 per cent. on boilers, and 25 per cent. on meters. Secondly, had the whole sum of £558 for law charges become due on the face of the accounts? This was not so. On what grounds did the Directors represent loss of capital? The Directors' ground was that it was notorious that it would be so, and they had taken it up under the best advice. They had discussed the matter for a very long time, and had come to that conclusion. Next, as to what course the Directors intended to pursue as to their fees? The answer to that question was given to Mr. Muirhead at the end of the last special meeting.

The **Solicitor** then answered Mr. Muirhead's objection to putting aside money in a redemption fund, because the 1888 Act provided for the purchase of the Company's business at a fair market value, arguing that it was the "then" value, and that the section should be read as a whole. **Mr. Muirhead**, however, reiterated his conviction that their property would be worth par at the end of the term, and might be at 100 per cent. premium. This discussion having terminated,

The **Chairman** said the next question was, did the Directors intend to replace the words in the articles, "not to exceed £1,500"? The Directors had no such intention. As to the printing charges, the Directors would consider the question of sending out a full report to shareholders. But, having regard to the fact that the printing expenses were high, they would hesitate to add to them. Would the Directors arrange for a meeting twice a year? They were quite prepared to consider that question. But, of course, having those meetings added enormously to the labour of the clerical staff and took up time. (A **Shareholder**: We pay for extra labour. Are we not to know what we are doing every half-year?) The Directors would consider the matter. The Chairman, returning to the list of questions, What was the amount paid for the new site? How long had the vendors held the property, and who was the surveyor? The amount paid was about £20,000. He did not know how long the vendors had held, but they were old holders, and there was a large number of them. The surveyor was Mr. Wilkinson, of 7, Poultry, E.C. The sum paid for the building contract was about £19,000. He could not say at that moment what sum had been spent on machinery, because they had not decided upon how much machinery was to be put in. That would depend upon the demand. As to the capital accounts of the two stations, the accounts were all kept in accordance with Board of Trade rules, and were audited by that Board. Answering the question, Why did they meet there (in the St. James's Restaurant)? the Chairman said it was because they were inside their own district, because the owner of the premises was a good customer, because it was close to the station, and because the Board thought it desirable to do so. The meeting, he remarked, was divided on the point whether they met there or in the City. If, however, the majority of shareholders would let the Board know that they preferred the meeting held elsewhere, they would meet them in the matter. As to what would happen at the end of the term of 42 years, supposing they were bought up by the local authority, to the surplus, if any, that accumulated, it would be divided in the proportion of 25 per cent. to the holders of vendors' shares, after paying back all capital to all shareholders. Having answered all the questions, with one exception, as he said, the Chairman put the resolution adopting the report and accounts, and declared it carried. So far as we could ascertain, there were 24 in favour and three against.

The **Chairman** next proposed the re-election of the retiring directors, Messrs. Egerton H. Clarke and H. Woodburn Kirby, but at the request of a shareholder, put the names separately. On his moving the re-election of Mr. Clarke,

Mr. Homan moved as an amendment that Mr. E. Clarke be not re-elected on the Board. Two of the Directors, he said, were not there (Mr. Clarke and Mr. Kirby), and they ought to have been. (The **Chairman** here interposed by reading a letter from Mr. Kirby stating his regret that he did not think he would be able to be present, as he was summoned as a witness at the Law Courts.) Whereupon **Mr. Homan** said he was perfectly satisfied with that explanation. Had the Chairman a similar letter from Mr. Egerton Clarke? (The **Chairman** said he had not.) Continuing, the speaker said that last Friday week, the 15th inst., being the day on which the Directors met to discuss the question of a dividend, Mr. Egerton Clarke actually sold on the Stock Exchange one founder's share, and having done so, came to the Board meeting to decide what the dividend on the founders' shares should be. Was that fair, equitable, or straightforward? That was not a speculative company, but one in which they considered they could put their money safely, and believed that when all differences of opinion were removed they would settle down into a steady dividend-paying concern. He thought, however, they had a right to expect that they had men on their Board who would not use the information they received as a means of jobbing in founders' or any other shares. Mr. Clarke sold the share at £355; the speaker was the buyer, so he knew something about it, though it was not bought for himself. Immediately afterwards the price went down to £270. He could not account for this, except that Mr. Clarke was about the Stock Exchange, he believed, as a buyer. He most strongly opposed Mr. Egerton Clarke's re-election to the Board.

This was seconded by **Mr. Muirhead** with the greatest possible pain and regret, because he would have liked to see Mr. Clarke present to answer or himself. At the same time there were certain facts concerning that Company which would not bear the light of day.

The **Chairman** said he was extremely sorry that question should have arisen, and was still more sorry that Mr. Clarke was not there to answer the allegations. He (the Chairman) had not the faintest notion that he was not coming. Of course he knew absolutely nothing of what went on on the Stock Exchange. He never went near it. But he could say that Mr. Clarke did not know what the resolution of the Board was going to be when he came into the room on that day (January 15). Was any notice given to him that it was intended to oppose his re-election?

Mr. Homan: No! Why should notice be given? His duty is to be here.

Mr. Davids asked whether the Board had at any previous meeting had any idea how the accounts were going to turn out.

The **Chairman** said the accounts were made up that very morning, and it was impossible for any Director to have a notion how they would turn out.

Mr. Davids: But the probable result had been discussed?

The **Chairman**: No. The auditor, who was there, would tell them when the accounts were made up. Not one of the points as to dividends, etc., were settled until the afternoon of the abovementioned day. (Several shareholders: Were they discussed?)

Mr. Homan said his point was that Mr. Clarke thought it advisable to sell his share. They had some reason to presume that he had a reason for selling it. Why did he do so? This ought to be explained by him in person.

Sir John Morris asked whether Mr. Clarke did not offer to buy back the share after selling it.

Mr. Homan said he could not tell.

The **Chairman** said he could safely say that the amount of the redemption fund was never discussed by any member of the Board before that afternoon, nor the amount of the dividend.

Colonel Francis asked who suggested the redemption fund if it was never discussed? He did not wish to imply that the Chairman was not stating what was not the case.

The **Chairman** said that he said the *amount* had not been discussed. As a matter of fact, the question of putting by that sum of money was discussed when he (Colonel Francis) was on the Board.

Colonel Francis stated that when he was a director it was said, What we will do is this: we must not give too large dividends to shareholders. We can give ourselves, as Directors, large fees—that, on my honour, is what occurred—it is easy enough to manage it.

The **Chairman** asked if Colonel Francis was speaking to any particular motion, to which the **Colonel** replied, "No; I am only answering questions."

The **Chairman** then put the amendment that Mr. Clarke be not re-elected a director, which was carried, there being apparently 20 in favour and three against it. He then, after a pause, stated that the Board thought it necessary to demand a poll. In answer to a Shareholder, who asked if the Directors were going to use their proxies in favour of Mr. Clarke, he said that the Directors would consider that point. Subsequently, he said they would not use their proxies for voting on this question. In order to give time to all parties to consider the matter, they had decided that the poll should take place that day week between the hours of three and half-past. (On the suggestion of a shareholder this was altered to between three and four), at the Company's offices. He hoped this would close the unpleasant incident for the time at any rate. He would be glad to appoint Mr. Homan scrutineer on one side, and the auditor on the other. This was agreed to.

The **Chairman** then proposed the re-election of Mr. Kirby as a director, which was seconded and carried unanimously, as also was the re-election of the auditors. This, he said, concluded the business of the meeting. There was one thing he would like to say, and that was that the thanks of the shareholders were due to their manager and secretary, Mr. Walker; their engineer, Mr. Dobson, and also to the staff for the energy and ability they had displayed. Night after night the staff had had to work up till 12 o'clock, because they could not get more people into the room at their disposal. Mr. Dobson, who had charge of the machinery and so on, had produced results which were shown by the report. He thought credit was often given to the Chairman and Directors when a large part of it ought to fall to the staff. This was carried by acclamation, and the proceedings terminated with a unanimous vote of thanks to the Chairman.

COMPANIES' REPORTS.

ANGLO-AMERICAN TELEGRAPH COMPANY.

The report of the Directors, which is to be presented to the half-yearly meeting of the proprietors held to-day (Friday), states that the total receipts from the 1st July to the 31st December, 1891, including the balance of £527 brought forward from the last account, amounted to £164,121. This sum, however, is subject to revision, as the lawsuit between this Company and the Paris and New York Telegraph Company is still pending before the Court of Appeal. The traffic receipts show an increase of £6,157 as compared with the corresponding period of last year, but this sum includes the adjustment of balances to 30th June last. The total expenses of the half-year, including repair of cables, etc., as shown by the revenue account, amount to £63,507. Interim dividends of 12s. 6d. per cent. on the ordinary stock, and £1 5s. per cent. on the preferred stock, were paid on the 31st October last, absorbing £43,750, leaving a balance of £56,864, out of which the Directors recommend the proprietors to declare final dividends of 16s. per cent. on the ordinary stock, and £1. 12s. per cent. on the preferred stock, amounting to £56,000, making a total distribution for the year ended the 31st December, 1891, of £2 12s. 6d. per cent. on the ordinary stock, and £5. 5s. per cent. on the preferred stock, leaving £864 to be carried forward to the next account. The Company's repairing steamship "Minia" has been engaged during the past half-year in the repair of the 1880 cable, the Brest-St. Pierre cable, the North and South Placentia cables, and the Duxbury cable. The "Minia" has also been employed in laying a cable from North Sydney, Cape Breton, to Canso, Nova Scotia, connecting this Company's system with the Western Union Company's cables between Canso and New York, thus providing an additional and alternative route, which, in the event of sudden pressure of business, or breakdown on the land lines, will be of great value. The new line completes through cable communication between England and New York City. The cost of the new cable has been charged to renewal fund. The Company's cables and land lines are in good working order, with the exception of the Brest-St. Pierre cable, which was again broken on the 18th November last, at about 275 miles from Brest. It is expected that the law-suit still pending between the Anglo Company and the Paris and New York Telegraph Company will be argued before the Appeal Court of Paris during the course of the coming month.

CITY AND SOUTH LONDON RAILWAY COMPANY.

Report of the Directors for the half-year ending December 31st, 1891, to be submitted to the fifteenth ordinary general meeting of the Company, to be held at Winchester House, on Tuesday next, February 2nd, at 12 o'clock.

Directors: Messrs. Charles Grey Mott (chairman), Harrow Weald Lodge, Stanmore; Charles Seymour Grenfell, Elibank, Taplow; Sampson Hanbury, Langford Park, Maldon, Essex; S. Barclay Heward, 57, Old Broad-street, London, E.C.; Edwin Tate, 21, Mincing-lane, London, E.C.

The receipts during the half-year from all sources amounted to £20,243. 15s. 4d. and the cost of working for that period to £15,516. 9s. 8d., leaving a net profit of £4,727. 5s. 8d. Including the amount brought forward from last half-year, the net revenue account shows a balance of £5,326. 0s. 9d.; of this amount the debenture interest absorbs £4,304. 10s., leaving a balance available for dividend of £1,021. 10s. 9d., out of which it is recommended that the full dividend of 5 per cent. be paid on the perpetual preference shares, and although the balance remaining would allow of a very small dividend on the ordinary shares, it is recommended that it be carried forward to the next account. The number of passengers carried by the railway in the past half-year was 2,749,055, showing an increase over the previous six months of 336,712, making the aggregate number carried since the opening of the line 5,349,580. Your Directors have, after mature consideration, found it necessary to vary the fares at certain stations between stated hours, with a result advantageous to the Company and to the comfort of the travelling public. To meet the convenience of residents along the line, a system of season tickets has been in operation since the 1st November last. Notwithstanding a considerable increase in the rates and taxes and other items over which your Directors have no control, they have satisfaction in reporting that the total expenditure shows a small decrease over that of the previous half-year, and it is hoped that some further reductions may still be made. The rolling-stock has recently been increased by the addition of the two new locomotives referred to in the last report, which it is hoped will give greater power and speed in working the trains, and the six additional carriages have also been delivered. The fourth engine and dynamo are now in course of erection for the generating station. During the past three months the traffic of the railway has shown a marked and satisfactory increase, which there is every reason to hope will continue and be still further augmented. To meet this growing traffic, arrangements are in progress for providing a more frequent train service during the busiest hours of the day. After the experience of the past year, there is every reason to be satisfied with the use of electricity as a motive power for the working of this railway, and for a confident belief that when all the details are fully perfected it will be found to be at once safe, convenient, and economical. The difficulties which have been experienced in dealing with the increasing traffic at the King William-street Station, owing to its confined dimensions and the steep incline leading to it, have induced your Directors to deposit a Bill by which they seek parliamentary powers to make a foot subway connecting the terminus of the London, Brighton, and South-Coast Railway Company at London Bridge with the station already authorised to be constructed at the corner of Denman-street, and also to construct two additional tunnels under the river with easy inclines to a central station at the corner of Lombard-street, and thence under Moorgate-street to The Angel at Islington, where ample siding room can be obtained at a small cost. These proposals meet with the approval of the Directors of the London, Brighton, and South Coast Railway, and will bring upon the line a very large and profitable traffic, and at the same time reduce considerably the cost of working the existing railway. It is also proposed to construct an inclined footway connection between this Company's station and the Monument Station of the Metropolitan and the Metropolitan District Railways, and powers for that purpose are included in the Bill. The Bill will be submitted for your approval at the conclusion of the half-yearly meeting. Owing to other engagements, Mr. Alexander Hubbard has resigned his seat at the Board, and the vacancy thus caused has been filled by the election of Mr. Edwin Tate, of 21, Mincing-lane, London. The director retiring is Mr. Charles Grey Mott, who is eligible for re-election. The auditors retire and are also eligible for re-election.

The statement of capital shows the total authorised capital to be £1,025,000—viz.: £800,000 in shares, and £225,000 in loans. £629,902 has been received in ordinary shares, leaving £20,000 unissued, and £9,216 in preference shares, leaving £140,380 unissued, the total share capital received being £639,118, and the amount unissued £160,380. An amount of £171,600 has been raised by loans, leaving available borrowing powers at December 31 last to the extent of £53,400. The total expenditure on capital account to December 31, 1891, was as follows: On lines open for traffic, £806,301; lines in course of construction, £7,942; and working stock, £34,100, a total of £848,344. Of this sum £825,828 was spent in the half-year ended June 30, 1891, and £22,516 in the half-year to December last. The total estimated expenditure on capital account during the ensuing half-year is £19,500, made up as follows: Lines open, £10,000; lines in course of construction, £5,000; rolling-stock, £4,500. Subsequent half-years are debited with an estimated capital expenditure on lines under construction of £145,000. To meet this further expenditure the accounts show capital powers and other available assets to the extent of £178,505. Maintenance of way and works, etc., during the half-year cost £491, of which £350 was for wages and £75 for materials. Locomotive and generating power cost £6,199, of which £100 was for salaries, £5,879 for running expenses (including £3,258 for wages and £1,985 for coal and coke), and £219 for repairs and renewals. Carriage repairs and renewals cost £365. Traffic expenses absorbed £6,369, of which £3,950 was for salaries, wages, etc., and £1,569 for hydraulics. General charges account for £1,592, of which

£650 went to Directors, £434 to salaries, and £272 to office expenses. We give below in detail the revenue account and the general balance-sheet.

REVENUE ACCOUNT FOR THE HALF-YEAR ENDING DEC. 31ST, 1891.

Dr.	£	s.	d.

PROVISIONAL PATENTS, 1892.

JANUARY 11.

548. **Improvements in holders for incandescent electric lamps.** Edwin Percival Allam, 8, Fountayne-road, Stoke Newington, London.

JANUARY 12.

568. **Improvements in electric incandescent lamps.** Godfrey Bamberg, 17, Weston-road, Southend-on-Sea.

576. **A new or improved automatic electric heat alarm.** Hugh Donald Fitzpatrick, 70, Wellington-street, Glasgow. (The Electric Heat Alarm Company, United States.) (Complete specification.)

638. **Improvements in telephonic switching appliances.** Parnell Rabbidge, 10, Southampton-buildings, London. (Complete specification.)

645. **Improvements relating to electric welding.** Peter Gendron, 45, Southampton-buildings, London. (Complete specification.)

JANUARY 13.

650. **Improvements in methods of operating alternating-current electro-motors, and in apparatus therefor.** Rankin Kennedy, Carntyne Electric Works, Shettleston, Glasgow.

JANUARY 14.

772. **Electric shade holder.** James Clerk Swanne, 53, Albyn-road, St. John's, London.

785. **Improvements in regulating sockets or fixtures for incandescent electric lamps and other translating devices, and in methods of regulating the flow of current to such lamps and other devices.** Elias Elkin Ries, 430, S. Broadway, Baltimore, Maryland, U.S.A. (Date applied for under Patents Act 1883, Section 103, July 6, 1891, being date of application in the United States). (Complete specification.)

791. **Improvements in laying and insulating electrical wires.** J. B. Hamond, 1, Quality-court, London.

798. **Improvements in electrical conductors.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, London. (Messrs. Siemens and Halske, Germany). (Complete specification.)

JANUARY 15.

825. **Improvements in electric cables.** Wallace Fairweather, 62, St. Vincent-street, Glasgow. (Eugene Francis Phillips, Unites States.) (Complete specification.)

831. **Improvements in fixed or movable electrical switch for incandescent lamps.** James Hunter, Leith, Scotland,

843. **Improvements in and connected with mounting incandescent lamps for safety purposes particularly applicable to electric miners' safety lamps.** Theophilus Coad, 1, Quality-court, Chancery-lane, London.

871. **Improvements in electric cables.** Henry Harris Lake, 45, Southampton-buildings, London. (David Brooks, jun., United States.)

873. **Improvements in electric lighting, and for other like purposes.** Robert James Rae, 79, Valentine-road, Walthamstow, Essex.

JANUARY 16.

925. **Improvements in telephonic receivers.** Alexander Marr, 70, Market-street, Manchester.

BUSINESS NOTES.

City and South London Railway.—The receipts for the week ending 24th inst. were £811, against £743 in the corresponding period of 1891, being an increase of £68. As compared with the week ending Jan. 17th, the receipts for last week show a decrease of £25.

Newcastle Electric Supply Company.—The annual general meeting of this Company was held on Monday at Newcastle. The report and balance-sheet were adopted, and a dividend at the rate of 4 per cent. per annum was declared for the year ending 31st December, 1891.

A Big Dividend.—At the annual meeting of Messrs. J. E. H. Gordon and Co., Limited, electrical engineers and contractors, 11, Pall-mall, held on 25th inst., a dividend of 30 per cent. was declared on the paid-up capital of £50,000, and a balance of £4,535 was carried to reserve.

NOTES.

Brindisi.—A telephone exchange has just been opened at this celebrated seaport town.

Budapest.—The transformer system only is to be used for the electric lighting of Budapest.

Dalton (Lancs.).—The Dalton Local Board have terminated their contract with the Gas Company.

Electro-Harmonic.—A smoking concert is held to-night (Friday) at the St. James's Restaurant, Regent-street.

World's Fair.—The Thomson-Houston Company will spend half a million dollars on their exhibit at the World's Fair.

Almanack.—We have received a handsome coloured perpetual almanack from Messrs. Woodhouse and Rawson, United.

Rapid Transit.—Pueblo, Colorado, has a complete system of electric railways—length 22 miles—which cost £120,000.

St. Petersburg.—The electrical exhibition at St. Petersburg, which opened last week, was attended by Mr. Edison.

Ipswich.—The Board of Trade have revoked the electric lighting order, 1891, of Messrs. Laurence, Scott, and Co., as asked by the promoters.

Electric Traction.—A large combination is being formed for the introduction of electric traction in Paris and the other large towns of France.

Thomson-Houston Lines.—The Thomson-Houston Company has installed 63 new electric roads, says the N.Y. *Electrical Review*, this year—rather quick work !

Royal Institution.—The Right Hon. Lord Rayleigh, F.R.S., will, on Saturday, February 13, begin a course of six lectures on "Matter: at Rest and in Motion."

Walton-on-Naze. — The Walton-on-Naze Sanitary Committee have the question of the purchase of gas works or other settlement of the lighting question before them.

Royal Institution.—Prof. Fleming will give the third of his lectures on "The Induction Coil and the Transformer" on Saturday, at 3 p.m., at the Royal Institution.

Train Lighting. — The Simplon Railway Company have arranged to light 50 of their carriages by electric light, the current to be obtained from Huber accumulators.

Electric Terminology.—The last electrical term, says *Industries*, is "hindrance." It amusingly suggests that perhaps hindrance, like other electric terms, is, in reality, a velocity !

Sofia.—The Mayor of Sofia has decided that the tenders for canalisation of Sofia are to bear mottoes or devices only, and the time for sending in has been extended to March 3.

Taunton.—Local opinion as regards the proposed purchase of the town seems to be in favour of letting the Taunton electric works continue yet awhile, and further demonstrate their success.

Gas Engines.—The next meeting of the Junior Engineering Society will be held on Friday, February 12, at the Westminster Palace Hotel, at 8 p.m., when a paper will be read on "The Gas Engine," by Mr. E. G. Walker.

Italian Telephone Lines.—A telephone line, the first that unites two Italian cities, has been opened at Milan, establishing telephonic communication between that city and Pavia. It is more than 30 miles long, and acts perfectly.

Bath.—During three months the lamps at Bath were out 244 hours, and the amount at 1½d. an hour, £1. 10s. 6d., was deducted from the public lighting bill. The committee have sanctioned the expenditure of £28 in testing instruments.

Bermondsey.—At the meeting of the Bermondsey Vestry last week, the General Purposes Committee reported that they had instructed the surveyor to obtain terms for lighting the streets from March 25th next, which course was approved.

Physical Society.—At the Science Schools, South Kensington, to-day (Friday), at 5 p.m., Prof. G. F. FitzGerald will read a paper before the Physical Society on "The Driving of Electromagnetic Vibrations by Electromagnetic and Electrostatic Engines."

Antwerp.—The contract recently concluded by the Antwerp Corporation with MM. Moris et Von Rysselberghe for public lighting on the "hydro-electric" system, requires a guarantee fund of £40,000. The light is to be supplied at less than the present price of gas.

Manchester. — The Manchester shopkeepers are becoming anxious to get the light at once, and Mr. Brooks, at the last City Council meeting, had to assure a questioner that no time was being lost, some of the contracts being already in hand, including those for engines and boilers.

Shoreditch.—The Shoreditch Board of Guardians have appointed a committee of five members to act with Mr. Smith, their architect, who has had several establishments fitted with electric light under his charge, to visit these installations and report upon the best scheme for lighting the workhouse.

Ice Carnival.—At the Theatre Scribe, Turin, on Wednesday, a white ball was given, the whole house being decorated with wintry scenery—ice, snow, glaciers, and all the picturesque accompaniments of the season. Moonlight was imitated by the electric light. All the ladies were dressed in pure white.

Utilisation of Water Power.— The Mulhouse Industrial Society, Alsace, have offered a premium of £100 for the best scheme of utilising natural water power, specially applicable to the needs of Upper Alsace. Projects, accompanied by sealed envelope containing name, must reach the society by May 15th.

Chicago Applications.—Intending exhibitors must not tarry if they mean to obtain space at the World's Fair. The date fixed for receipt of applications is the 29th of February, and after that date applications can only be received subject to space being available. The London office is at the Society of Arts, Adelphi.

Institution.—On Thursday next, Feb. 11, a paper will be given before the Institution of Electrical Engineers by Alexander Siemens, vice president, on "Some Experimental Investigations of Alternate Currents." The discussion on the above and Mr. Preece's paper on the "Specification of Conductors," will be held on the same evening.

Denbigh.—The Town Council of Denbigh have had the question of the purchase of the gas works brought before them. Mr. Howel Gee thinks Denbigh well situated for lighting by electricity, and it is to be hoped he will be supported. The Mayor is to draw up a report of the cost of the scheme for public control of the lighting.

Tewkesbury.— The Tewkesbury Urban Authority have before them the question of applying for a provisional order for the supply of electric light, and the clerk has been instructed to make enquiries. There should be the

possibility of utilising the power of the Avon or Severn, we fancy, for generating of light for Tewkesbury.

Electric Welding.—Mr. Coffin, of Detroit, proposes to weld electrically by a combination of arc and incandescent systems, first making his joint hot by contact with a conductor, and simultaneously springing an arc between the said conductor and another near the point of contact, welding the metal when at the desired temperature.

A New Alternator.—The Helios Company have recently patented a peculiar dynamo, having a long armature and two sets of field magnets. At one end of the armature these are placed above and below, and at the other end at the sides. The dynamo is apparently to be used for generating alternating currents varying in phase for transmission of power.

Portsmouth.—The Portsmouth Town Council on Tuesday revoked its previous decision to light the town with electricity on the low-tension principle, and adopted a new high-tension scheme, estimated to cost £38,000. An amendment for deferring the scheme until the question of using tidal power for machinery was considered was lost by the Mayor's casting vote.

Llanelly.—At the meeting of the Llanelly Local Board held on Monday, the question of electric lighting of the town arose out of the minutes of the previous meeting. It was remarked that if the Board intended to take advantage of the provisional order, something should be done at once. The clerk stated that the Board had already determined to advertise for tenders.

Cork Tramways.—The Cork Corporation have adopted the recommendation of the Standing Committee that, subject to plans being approved and other conditions deemed advisable, the Corporation give general approval of the proposed scheme of street tramways. We believe there is some idea of running these trams by electric traction if suitable arrangements can be made.

Society of Arts.—The third of Prof. Forbes's Cantor lecture, on "Electrical Distribution," will take place on Monday next, at 8 p.m., at the Society of Arts, when the following will be dealt with: Transmission and distribution of electricity derived from lighting circuits; effect on load factor; separate circuits for power; distribution for street and other railways; utilisation of water power by electric transmission to a distance.

Pontypridd.—The proposal is before the Pontypridd Local Board to purchase the gas works, the gas company being willing to sell or extend their works as the case may be. The Pontypridd Electric Lighting Company have offered to light the centre of the town by electric light, and the clerk was instructed to obtain particulars of the success or otherwise of Taunton. We hope the result will be a central station for Pontypridd.

Schanschieff Batteries.—A correspondent writes that, instead of costing 7s. 6d. per unit, these batteries can produce electrical energy at 2s. 6d. per unit, "and hopes with careful experiment and better management" to reduce the price still further. The same correspondent points out that the proposed capital of £50,000 consists of £5,000 cash and £45,000 paper—the latter going to the vendor, who receives nothing till 10 per cent. has been paid on the £5,000.

Milk Ivory.—According to a recent note in the *Chemical Trades Journal*, it appears that a substance termed "lactitis," much like ivory, is now made out of milk. Curds are taken, mixed with borax and a mineral salt, such as sugar of lead, blue vitriol or other, and pressed with great force. The resulting mass is hard and resisting, *capable of* replacing ivory, celluloid, and ebonite, though being an animal substance its electrical resistance will probably be low.

Cyclometer.—Ransome's cyclometer for showing the variations of speed in the motors used for electric lighting is made by Messrs. Manlove, Alliott, and Co., of Nottingham. It is capable of representing the fluctuations of speed during a single revolution of the motor-shaft, and hence of indicating whether or not the flywheel is heavy enough. The intervals of time are measured by a vibrating tuning-fork, which by means of a stylus describes a wavy line on a revolving barrel of smoked paper.

Sea Telephone.—The question of telephoning between ships at sea is evidently one which is exercising the brains of inventors. We mentioned Edison's plan last week, and we notice that an elaborate patent has been taken out by Ernst Huber and Fred. J. Kneuper, of New York, for an instrument similar in its aims, but which, apparently by means of "sound-interceptors," is to register sound vibrations transmitted through the water, part of the apparatus dipping into the sea below the ship.

Springfield (Essex).—A public meeting was held recently with reference to the public lighting of Springfield by electricity, and Mr. T. H. Dennis undertook to see Messrs. Crompton and Co. with a view to obtaining an installation. Messrs. Crompton wrote that they could not undertake the public lighting alone, but if there were private consumers they might make an offer. A canvass has been made, and it is thought there is a fair chance of the light being adopted. Messrs. Christy and Norris have also made a canvass.

Life Belt Cushions.—The "Combinare" cushions, made by Mr. T. Steward, at 32, Gray's-inn-road, are worth attention by all interested in naval matters. They are suitable for boats and ships of every description, and in case of need form most efficient life buoys. They are lighter than cork, and impervious to damp. They are being taken up largely by the British and also foreign Governments, and we understand that the General Electric Traction Company will replace all their boat cushions with this "Combinare" cushion

New Insulating Material.—A novel and permanent insulating material for electric wires and cables forms the subject of a patent by Mr. Thomson Griffiths, F.C.S., of Dashwood House, City, the well-known authority on pigments. By this invention, it is said, a saving is effected of about 50 per cent. over those in use. It is stated to be not only of a most durable and permanent character, but that the insulating power of the cables and wires is greatly increased, while the mode of application is extremely simple and inexpensive.

Liverpool.—A numerously signed memorial was read at the Liverpool City Council requesting the Council to give their consent to the application by the Liverpool Electric Supply Company for a provisional order whereby the company would be bound to reduce the price to 8d. per unit. Mr. Hornby stated that the Council were determined to oppose the application, as under the 1889 orde they had power to buy up the most important part of the undertaking in 19 years, and they would not give up this power without some considerable concession.

Camberwell.—At the last meeting of the Camberwell Vestry the General Purposes Committee, through Mr. Wallace, reported the receipt of a letter from the engineer of the Camberwell and Islington Electric Light and Power Supply, Limited, formally acquainting the Vestry with the information that their Bill passed both Houses of Parliament last session, and received the Royal assent; also that the company had made the deposit of £2,000 required by the Board of Trade, and that it was anticipated that the

new system of lighting would be inaugurated early this year.

Cable to Lundy Island.—Public attention has lately been called to Lundy by H.M.S. "Banterer," and much surprise has been expressed that a much-frequented harbour of refuge should have no telegraphic communication. A cable was laid in 1884, but did not receive sufficient support, and the cable was sold to Mr. Rogers, the maker of it, who has removed it to London. If a new cable is laid, it is thought better to lay it to Braunton, seven miles extra, when the Chamber of Commerce would subsidise the company. The old cable is still available, and could be relaid at small cost.

Hastings Company.—At the annual meeting of the Hastings and St. Leonard Electric Light Company, recently held, the chairman said the respectable dividend of 7½ per cent. was declared in the report, this leaving a balance of £320 over. He reminded them that last year the directors had not only given their services, but made themselves responsible for debts. He thought £200 was not too much to be given to the directors, leaving £120 to be carried forward. He passed a word of sympathy for nervous shareholders who had sold their £10 shares for 25s. after what was said in the papers. The report and the chairman's recommendation was adopted.

Electric Lifts for Railways.—The use of electric motors for lifts and drawbridges has achieved sufficient success for there to be any doubt of the possibility of their use in moving large weights when so required. In the City and South London Railway, as will be remembered, the lifts which carry the passengers to and from the ground level are hydraulic lifts, but we have reason to believe that on the newer ventures, such as the Central London electric road, electric lifts will be used. This will, of course, do away with the necessity for separate generating plant and distributing mains, and will simplify the station arrangements considerably.

Electricity from Wind Power.—At the last meeting of the Royal Scottish Society of Arts, Prof. Blyth, of the Anderson College, Glasgow, read a paper on the "Utilisation of Wind Power for the Generation of Electric Light." After alluding to his previous experiments, Prof. Blyth stated that last summer he had used a machine on the principle of the Robinson anemometer, with hollow cups, rotating horizontally. It worked satisfactorily, and in a fair wind gave out 4 e.h.p. Even in a gale it ran satisfactorily. Prof. Blyth is an ardent supporter of the use of wind power for electric light, and his example should stimulate others to follow his and Mr. C. F. Brush's example. It will be remembered that Mr. Brush has a "wind turbine" in his garden for supplying his electric light.

Budapest Electric Tramway.—The success that has attended the introduction of electric traction into the streets of Budapest is a good augury for the extension of electric railways in Europe. It will be remembered that this line is upon the open-slotted conduit system, more particularly advocated in this country by Mr. Edward Manville. The Budapest railway was equipped by Messrs. Siemens and Halske, who deserve great credit for the success achieved. The mileage has lately been increased from 5½ to seven miles, most of which is double track. They now have 62 cars in use, and the mileage last year attained 24,000 miles, double that of the previous year. The power of the generating station now amounts to 700 h.p. The number of passengers carried last year is given as 8,619,215, as against 4,459,234 in 1890.

Chiswick.—At the last meeting of the Chiswick Local Board, Mr. Harry Smith moved, in accordance with notice, "That instructions be given to the surveyor to enquire and report as to the persons desiring a supply of electric light in this parish." Mr. Smith pointed out that there was a company willing to introduce electric light into the parish providing they could obtain a sufficient number of consumers. He thought that a majority of the inhabitants were in favour of the electric light, and he would propose that a memorial be drafted and the ratepayers canvassed. Mr. Adamson suggested that they might draft a circular and ask the ratepayers to sign it. In reply to the chairman, Mr. Smith said that the cost of the electric light would be about one-third more than that of gas. The arrangements for canvassing were left in the hands of the clerk.

Ventilation and Lighting.—Besides electrical contractors and the householder himself there is one class of professional man to whom a good knowledge of the advantages of electric light is worth money—and this is the sanitary engineers, who have often to advise upon the internal arrangements of high-class dwellings. We are pleased to see that at one of the lectures for sanitary officers held at the Parkes Museum in connection with the Sanitary Institute, the question of electric lighting was dealt with by Sir W. Douglas Galton, his subject being ventilation, warming, and lighting. After describing methods for changing the air in rooms, the question of impurities from illuminants was gone into, oil being recommended as preferable to gas both as regards products of combustion and amount of heat. But the only really hygienic light was the electric light. Sanitary engineers are rapidly recognising this fact, and Sir Douglas Galton's lecture will probably turn still greater attention to the necessity of considering hygienics as well as light in household illuminants.

Liverpool Electric Football Club.—The above football club held their second annual dinner at The Eagle Restaurant, Liverpool, on Saturday last. The dinner was preceded in the afternoon by a football match between the married and single members of the club, which the benedicts won by four goals to one, reversing last year's verdict, when the single men won by five goals to nil. In the evening the party, numbering about 80, included Mr. A. B. Holmes, managing engineer of the Liverpool Electric Supply Company, Limited, Mr. B. H. Collins, secretary, Mr. A. Clough, works manager, and Mr. Naftel, chief electrician. The dinner was followed by a miscellaneous entertainment. The proceedings commenced with a pianoforte solo and banjo song, after which Mr. Collins proposed the toast of "Success to the Liverpool Electric Supply Company, Limited," to which Mr. Holmes responded, referring to the progress of the company since its formation and its present satisfactory condition. Songs and instrumental music interspersed with toasts occupied the remainder of the evening, which was brought to a close by the singing of "Auld Lang Syne" and "God save the Queen."

Sims-Edison Torpedo.—On Wednesday an official trial of the Sims-Edison torpedo by the military authorities took place at Portsmouth before the Duke of Connaught, Major-General Geary, and others, who went out to the "Drudge," a steam vessel lent for the purpose of the test by the Elswick Company. Mr. Sims, Captain Hamilton, and Major Palliser, directors of the Sims-Edison Company, attended. The torpedo, it will be remembered, is driven and controlled by two electric wires from a dynamo, the body is submerged, and two flagstaffs show the direction of movement. In the test, the torpedo was first sent by Mr. Sims at right angles to the ship at a speed of about 10 knots. When three-quarters of a mile off the torpedo crossed the bows

and described a semi-circle, at a speed of 16 or 17 knots against tide, and in a choppy sea, in which it was frequently submerged. Having run out 7,000ft. of wire inside the torpedo and another 4,000ft. on board the ship, it was brought to a dead stop as if for exploding. The advantages claimed are that the Sims-Edison torpedo is controllable at any distance within its range, without the necessity for other fixed plant than switches and dynamo—the ordinary lighting dynamos of some of the large battleships giving ample current.

Aston Baths.—The Baths Committee of the Aston Local Board report that they have had under consideration the question of the lighting of the public baths. They are advised that there will be sufficient engine power to generate electricity for the public baths, and also for the Public Buildings. The committee have obtained tenders for the electrical installation of the public baths and also the Public Buildings. In discussing these tenders, the committee state that, notwithstanding the initial outlay for dynamos, storage batteries, cables, wiring, fittings, etc., the electric light can be substituted for gas and a saving effected of £74 per annum, which at 4 per cent. per annum, the interest on a capital sum of £1,850, would be a clear saving as compared with the cost of lighting by gas. From this amount some allowance should be made for depreciation of plant and towards the cost of attendants' wages, etc., but at present it is impossible to accurately fix this amount. In the circumstances the committee unanimously recommend the Board to adopt the electric light for the public baths, and to substitute this mode of lighting for gas at the Public Buildings, and that the tender of Messrs. Fowler, Lancaster, and Co. for the execution of the work, at the sum of £1,594, with the sum of £30 per annum for the maintenance for a period of five years, be accepted.

Electric Light at the World's Fair.—Some 50 separate contracts are to be let for the electric lighting of the Chicago Exposition buildings and grounds. In all there will be used, according to present plans, approximately 127,000 electric lamps, of which 7,000 will be arc, of 2,000 c.p. each, and 120,000 incandescent 16-c.p. lamps. To run the plant, 22,000 h.p. will be required. By the awarding of separate contracts for the lighting of each of the buildings and of different sections of the grounds, all electric firms, whether large or small, have an opportunity to participate and to show what they can do, and at the same time a variety in illumination will be effected. One of the distinctive features of the electrical display will be that made in the main basin. Special attention will be given to the illumination of this basin, and it will be encircled by 1,650 incandescent lamps. The lamps are to be 2ft. apart and 3ft. above the surface of the water of the basin. In the great Manufactures Building alone there will be 33,000 lights. The plans prepared by the electrical experts call for ten times the capacity of all the plants used at the Paris Exposition. The World's Fair directors will spend 1,000,000dols., and perhaps more, for these electric plants. Exhibitors will not be required to pay anything for light, except in cases where they call for more lamps than are furnished by the construction department. In that event, they will be furnished additional lamps at actual cost. Electric power will be conveyed over the grounds in a system of underground conduits. Some of the wires will, however, be hung from the structure of the elevated railroad.

London Provisional Orders.—The Highways Committee of the London County Council report that they have had before them seven provisional orders for which application has been made by the Board of Trade. These are as follows: 1. County of London, North (parishes of Islington, Clerkenwell, and St. Luke; Holborn district). 2. County of London, South (parishes of Lambeth and St. George-the-Martyr; Wandsworth district). 3. East London (Hackney district). 4. North London (Hackney district; parishes of St. Luke and Clerkenwell). 5. St. Mary, Islington (parish of Islington). 6. South London (St. Olave's and St. Saviour's districts; parishes of St. George-the-Martyr and Newington). 7. West London (parishes of Hammersmith, Fulham, and Battersea; and part of Wandsworth district). The committee have submitted certain amendments to the Board of Trade, and informed the Board that where powers are sought over the same area by the local authority and by a company, their opinion is that the former should be preferred. They have also considered a model order (form No. IV.), forwarded by the Board of Trade for the Council's observations, for use in cases where the local authorities are the undertakers. There are four of these orders applied for this session—viz., Hampstead, Lambeth, Shoreditch, and Whitechapel district orders. They have directed that certain amendments, which they think necessary in order to make the form of order correspond with previous legislation, shall be submitted to the Board of Trade, these amendments relating principally to the insertion of clauses relative to the keeping of separate accounts, removal of existing overhead lines, inspectors' fees, protection of the Council's works, regulation of price, and so forth. They also report that formal notice of the revocation of the Wandsworth district order has been received from the Board of Trade.

Priority and Cost.—The following interesting letter written by Mr. John Sellon to *Lightning*, in answer to a question as to the first house lighted by electricity, deals suggestively with the cost of the electric light, and is worthy of extended quotation by electric light promoters: "I commenced wiring my house early in 1881; at Easter of that year my electric light shed was completed, and I was soon afterwards running my lights with a Schuckert dynamo, which I had by me for experimental work—later on replaced by a Brush. The wiring was carried out entirely under my own supervision, and as suitable fittings for the light and even good switches and other details were then unknown or unprocurable, I had all mine made by workmen of my own, the ornamental glass work being also specially made for me after my own designs. As they were then—1881—so in the main they are now, 120 lamps throughout the house from top to bottom, every room and every outhouse being so lighted. I naturally experienced at first some troubles and annoyances, chiefly from flickering of the light, and the necessity of running the dynamo all the time that any light was needed. It was these inconveniences which induced me to turn my attention to secondary batteries, my first patent for which was taken out in September of that year. After some crude attempts, I at last, quite early in 1882, was running my entire system with accumulators, almost as perfectly as it runs to-day. I have made no material alteration or addition since that time, meanwhile my lighting has been entirely free from interruption, beyond a few hours when altering or changing the accumulators, and a short stoppage or two through failure of the supply of gas for my engine. The saving to me directly and (but of course chiefly) indirectly, I consider to have been close upon £100 a year throughout the decade, during which the ceilings and decorations of all the principal rooms have not been even touched up, and they at present shows no signs of wanting it, while the comfort enjoyed has been beyond estimate."

OUR PORTRAITS.

Eason, W. B., born in 1858, is a native of Aberdeen, in which town he received his early education, but after three years' apprenticeship in the engineering works of Messrs. McKinnon and Co., attended the Royal School of Mines lectures in engineering. After more practical engineering experience at the Thames Iron Works, Mr. Eason attended Prof. Ayrton's lectures at Finsbury, when his introduction to the electrical world may be said to have taken place. In 1883 he went to Messrs. Paterson and Cooper as electrician, and soon after became manager. With this firm he still remains, and it is not too much to say that the extension of the firm's work in various directions is due entirely to the energy and ability of the manager. Mr. Eason has a three-sided character—he is a worker, a thinker, and a good companion. We hardly know what more can be required of a man. His contributions to the technical journals and to the Institution's *Proceedings* are always of a very practical nature, and mark him as one of the leaders in the profession. That he is ever ready to help beginners is well shown by the work he has done for the Old Students, of which society he was re-elected president for the current year.

Baker, Sir B., is known better in connection with the Forth Bridge and other works of a similar character rather than as an electrical engineer, although he is one of the recent elections upon the rolls of the Institution of Electrical Engineers. Sir B. Baker's early training was that of a mechanical engineer, with a subsequent extensive experience in the work of a civil engineer. After his arrival in London he entered Sir John Fowler's office, and gradually took a more and more active part in the many engineering works carried out from this office, including, amongst others, the Metropolitan Railway. But, as we say, it is his connection with the Forth Bridge that looms most conspicuously before us. Of this great work we have no occasion to speak, but it may be noticed that Sir B. Baker called electricity to his aid in carrying out the work. He is a member of most of the great engineering societies, and has largely contributed to the literature of this subject.

Binswanger, Gustav. Born in Bavaria in 1855, and received his education at the Polyteknikum, Augsburg. He has resided in England since 1873, becoming naturalised in 1879, when he began business as electrical engineer and manufacturer of electrical apparatus. The factories and business establishments which he has conducted since that period have experienced a rapid growth and extension, in keeping with the increase of electric lighting and telephonic business in general. At Mr. Binswanger's first factory at Homerton the number of hands employed was about 10; his works at Chapel street, Manchester, now employ from 500 to 600 workpeople, and the employés engaged in electric work at the head office in Queen Victoria-street, and the branch warehouse in Great Saint Thomas Apostle, at Glasgow, Melbourne, and Cape Town number about 200. To Mr. Binswanger's efforts and business and technical capacity are due a number of improvements in the use of electricity for lighting, motive power, and heating. We will mention only his early introduction of electricity meters, his improvements of electric fittings, such as switches, roses, connectors, etc., his introduction of electric motors for domestic purposes, and his system of electric heating by the process of embedding platino-iridium resistances in layers of enamel. Mr. Binswanger's attention was also given at an early date to telephony and electric signalling, and the position which his house holds in this branch of applied electricity testifies to the success which has attended his efforts. Mr. Binswanger has issued a great many effectively illustrated catalogues, mainly with the object of popularising electric lighting and telephony, and throughout his career in connection with electrical enterprises his main effort has been to induce the general trade of engineers, gas engineers, plumbers, etc., to introduce electric lighting, and thus make it known and popular in districts and places where the establishment of a purely electrical enterprise could not have been a pecuniary success. Mr. Binswanger is principal proprietor and managing director of the General Electric Company He is a member of the Institution of Electrical Engineers, Fellow of the Society of Arts, and on the Council of the Electrical Section of the London Chamber of Commerce.

Grindle, G. A. Educated privately, and afterwards at Oxford. In 1876 entered the School of Telegraphy and went through a course, and subsequently visited India and America, returning 1880. In the same year entered the service of the Anglo-American Brush Company, passing through the shops, and carried out several installations for them, finally taking charge of the City of London experimental lighting (Brush section) 1881. In 1881 was appointed chief electrical engineer to the Eastern Electric Light and Power Company, Limited, and proceeded to Egypt, where he carried out several installations until compelled to leave at outbreak of Anglo-Egyptian War. Returned to England, and for several months was engaged experimenting for Eastern Electric Light and Power and Indian and Oriental Storage and Electrical Works Companies, Limited, conjointly, chiefly on storage batteries, then proceeded to Bombay to take charge of the Eastern Electric Light Company's operations in India, where he carried out numerous installations. Returned to England in 1884, and was appointed manager to Belfast Electrical Appliances Company, erecting for them various important installations in Ireland. In 1886 entered into private practice in London, and in 1889 was appointed resident engineer for Messrs. Mather and Platt on the City and South London Railway undertaking. He now remains in Messrs. Mather and Platt's service.

Wallace, R. W. Born in 1854. Educated privately. Graduated at London University: is a well-known barrister, who was called to the bar in 1884. Director of Kensington and Knightsbridge Electric Light Company, and of the Westminster Company. Has been counsel in many important engineering and chemical cases, such as Kirk and Randall *v.* East and West India Docks, Nettlefolds *v.* American Screw Company, Rawes *v.* Chance Bros. (alkali recovery); in electrical matters mostly for electrical companies; in Edison feeder patents; at present in Lane Fox *v.* Kensington Company, and Hopkinson *v.* St. James's Company. Author of a work on patent law. Associate member of the Council of Electrical Engineers. Before called to the bar he was inventor of many important processes in the manufacture of chemical products, and in processes for gas purification. He was engaged as counsel for a large number of electrical companies before Major Marindin, when London was divided up for electrical purposes. He is working at present with the Duke of Marlborough in improving the telephone service in the United Kingdom, a work which it is devoutly hoped will be successful, for there is great need of such improvement.

CRYSTAL PALACE.

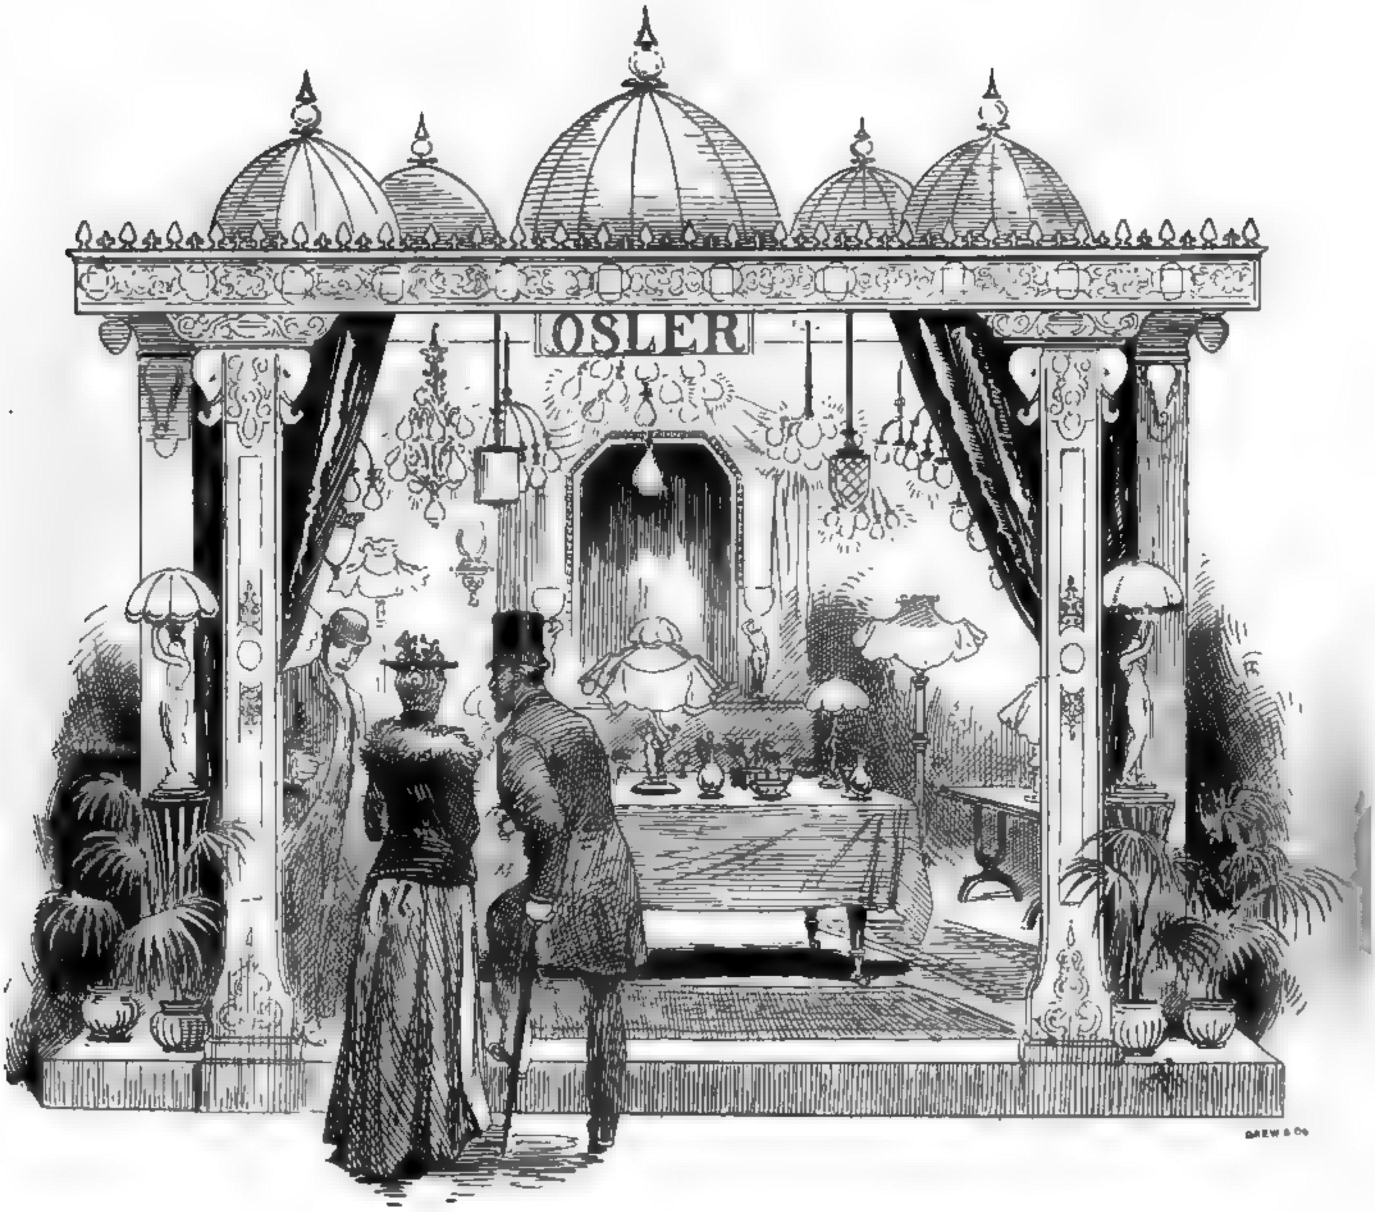
The Lord Mayor and Lady Mayoress are to visit the Crystal Palace to-morrow, and the Exhibition, which has already been opened without ceremony, will have additional attention called to it in the minds of the public after this public function. Many persons have put off paying even a preliminary visit, hearing that the exhibits were not ready, but the whole Exhibition is now practically in shape. Almost all the stands are complete, and those that are not only requiring a last few finishing touches; the machinery is nearly all in running order, and what may be termed the side shows—such as Messrs. Siemens's model theatre, the high-tension experiments, the drills, electric lifts, electric cooking, the Edison-Swan screen, and so forth—are now or will be in working order on Saturday, and regularly from the beginning of next week.

Messrs. Crompton and Co., have had their crane going this week—travelling, slewing, hoisting—the current being supplied from their own dynamos. Inner rails have been laid, covered with thick strip copper, which conduct the current. It is necessary, by the way, to remark that the speed of hoisting of this crane is two tons 80ft. per minute—and not per second, as given in a former notice,

which would be at the rate of nearly a mile a minute. In action this crane will be a constant centre of attraction, demonstrating the possibilities of the use of electric power.

When the incandescent lamp came into vogue there was much discussion as to what was the proper class of fitting to adopt for it. The lamp was so dainty, delicate, and fairylike, that it made the heavy coarse gas fittings look grotesque. Evidently designers must begin over again. Among those who have resolutely set themselves to forget all about gas and its fittings are **Messrs. Osler,** of 100, Oxford-street, W., who have struck out quite a new line. They have gone to Dame Nature for advice, and have adopted one of her most graceful productions as their model—we refer to the fuschia. Not only so, but discarding metal they have adopted cut glass as the material of their fittings. As to the effect of this departure our readers can judge for themselves by paying a visit to Messrs. Osler's stand (No. 5), which is certainly in its way one of the attractions of the Exhibition.

The structure has been designed in the Eastern style, the top being surmounted by domes, and supported by pillars. The decorations are in keeping with the structure, and altogether the firm make an attractive show. The centre dome is lighted by a very handsome 25-light electrolier in cut glass and polished brass. A draped mirror surmounts a mantel-piece, on which stand Grecian figures in Worcester porcelain, which have been specially designed by the Royal Worcester Porcelain Company. Here also are vases in cut glass having incandescent lamps inside, and giving a very pretty effect. In various parts of the stand are electric standards in cut glass, brass, and china, the workmanship of which is sure to be admired. The stand is handsomely draped with curtains. Between the columns which support the roof at the front of the stand are two Grecian figures, one on either side, carrying lamps with specially-designed shades. The figures are of Worcester porcelain, and are remarkably graceful. On a table in one corner are some flower-stands of special design in cut glass, fitted with one or more lamps. Ladies should be able to produce some very pretty effects with these stands. Another standard for tables has a centre-piece for holding the lamp, while below are receptacles for flowers. In the centre of the apartment is a table specially decorated and arranged to show the simple way in which the electric light can be used for this purpose. The floor is covered with Eastern matting, over which are laid Oriental rugs. The sketch which we publish herewith will give those of our readers who have not seen the Exhibition a very good idea of Messrs. Osler's stand.

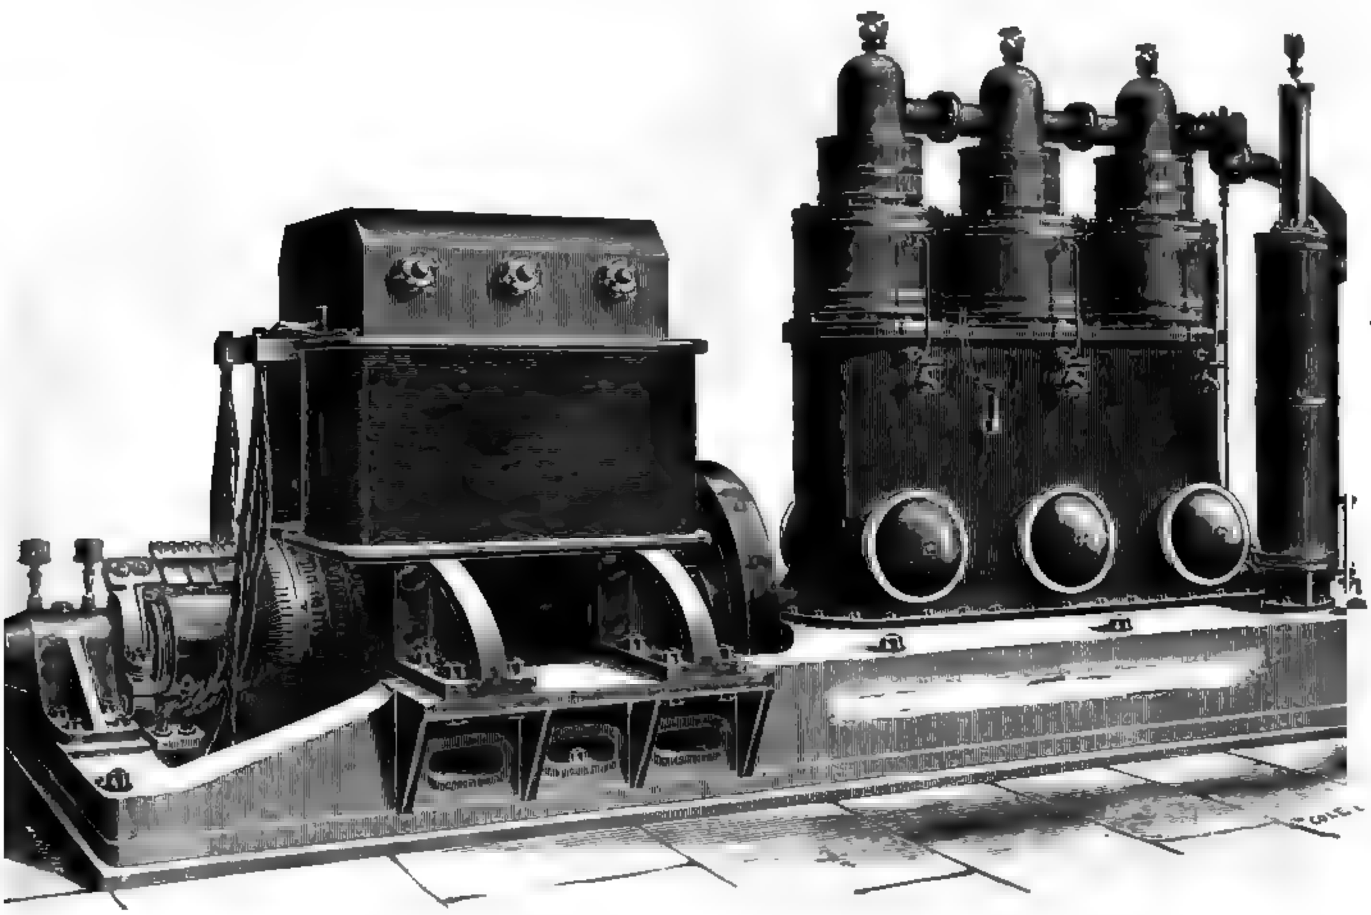


Sketch of Messrs. Osler's Stand at the Crystal Palace Exhibition.

The General Electric Company have a peculiarly original stand to themselves in the centre of the South Nave. Its tall pyramid, or Cleopatra's needle, with four sides made of thousands of switches, cut-outs, ceiling roses, and wall sockets, can be seen from afar down the transept, and fitly symbolises the company's position as wholesale makers of these most necessary fittings for house adornment by electric light. Large mirrors give an imposing appearance to the base of this stand, around which are crowded a plethora of electrical apparatus, instruments, telephones, batteries, bells in variety too numerous to mention. Standing around

are a number of interesting examples of the use of small electric motors for easing household labour, and boot-blacking machines, knife-cleaning machines, churns, fans, pumps, and so forth, will all be shown working. But perhaps the most interesting feature of this stand will be the electric cooking and heating apparatus. The Lady Mayoress is to be presented with a steaming hot pancake baked by electricity, with the apparatus made by this company, and the Lord Mayor may have his hat ironed by an electric heater if he so desires. Flexible wires connected to a wall socket serve to carry all the current that is needed. In the case of the electric cooker this current is about three amperes at 100 volts, and this is sufficient to heat three hot-plates for baking or grilling. Electric foot warmers and car or room heaters will also be shown, and it may confidently be expected that the continual demonstration of the cleanliness, simplicity, and ease of application of electric heating at the Exhibition will cause many persons to have it adapted to their houses along with the electric light.

avoid all this, and show at one glance the direction a vessel carrying it is steering. It is a simple but highly-ingenious arrangement. A strong lamp is placed inside a glass case, which is shaped somewhat like a small bath placed edgeways, that is, having the front circular plate smaller than the back one, the sides being of opal glass. The front and back plates are opaque, but a large cross is left on the back plate. The effect of this simple case for the lamp is, that when the ship is coming straight end on towards a person, a round ring of light is seen; if the vessel steers to port or starboard a crescent of white light is seen, the horns pointing in the direction that the vessel is approaching. When going direct away the cross is seen, and in other positions, combinations of ring, crescent, rectangle, and cross are given, visible by the eye at a mile away, and with a glass at two miles, giving an immediate indication of the vessel's direction. When it is remembered that nearly a third of the casualties at sea occur from collisions, that this is the captain's greatest dread, that the sudden appear-



Siemens Central Station Set of Dynamo and Triple Compound Engine.

In the very centre of the Palace, in front of the orchestra, a wide and deep space in the floor has been fitted up as a beautiful underground grotto with fountain. This is to be lighted by electric light by **Messrs. Laing, Wharton, and Down**, and the fairy lamps will enticingly glitter and glisten amongst sparkling showers on rock and ferns springing up from the centre of the floor.

There are two novelties which we noticed at our last visit to the Exhibition which are worthy of particular attention. One of these is a new lamp for the better direction of ships' courses at sea, and specially for the avoidance of collision—termed the Crescent Course Indicator, the invention of **Mr. J. Fletcher Wiles**, of Lloyd's, Royal Exchange, and Crescent Works, South Croydon. As is known, the ship's lights usually consist of a red and green light. This arrangement, although until the present nothing better has been suggested, suffers from two defects: First, the green light does not always show as far as the red from difference in penetrating power; and secondly, and more important, the captain on another vessel cannot be certain of the *direction* in which the ship is going until one of the two lights disappears, sometimes too late to avert a catastrophe. The Crescent indicator is to

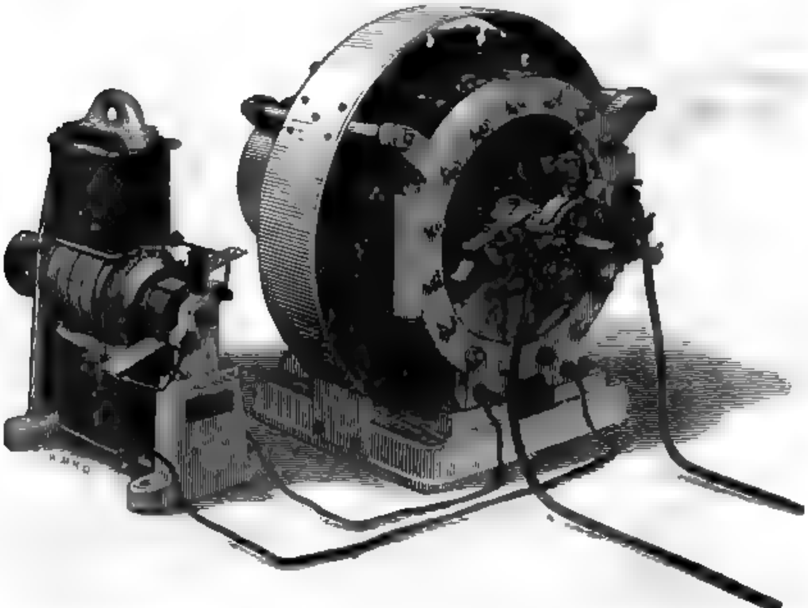
ance of lights in a fog do not now enable a captain to give his orders without a few moment's delay to ascertain the strange vessel's direction—moments that mean all the difference between a collision or otherwise; when it is stated that many companies only ensure their vessels against collision, taking all other risks themselves, it can be seen what an advantage a thoroughly distinctive light would become. This light can be seen at the Weymersch battery stand, and has received considerable attention from naval men. It is stated that seamen can tell the alteration of a single spoke of the wheel by the change in the look of the crescent or ring. It is proposed to make all lamps the same standard size, so that the size of the light gives some indication of the distance of the ship.

The other novelty we mentioned as worth attention is a new speed indicator—the "Showspeed"—invented by Mr. James Murdoch Napier, M.I.C.E., and shown by **Messrs. D. Napier and Son**, Vine-street, Lambeth. It is one of the simplest and most accurate and effective speed indicators we remember to have seen. All it consists of is a revolving drum filled with mercury, driven by a strap and worm gearing, the drum having an upright glass tube, in which is placed an ivory

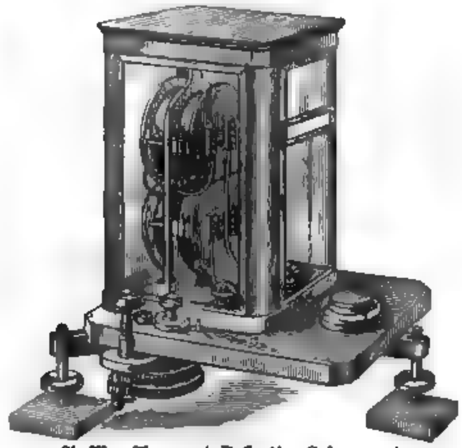
float having a black mark upon it. The rotation by centrifugal action forces the mercury up the tube in proportion to the speed, which is read off on a plainly visible scale attached to the tube. The indicators are constructed for various speeds, from 100 up to 1,000 or more revolutions, and already several of them are in use at the Exhibition for dynamos and engines.

No other exhibitors at the Crystal Palace have, we think, a collection of so many and important exhibits of electrical machinery, plant, instruments, apparatus, and practical applications of electricity generally for light, power, signalling, and all other uses under the sun, as have the world-famous company of **Siemens Bros. and Co., Limited.** We propose in this article to describe and illustrate some of their exhibits more particularly and in detail.

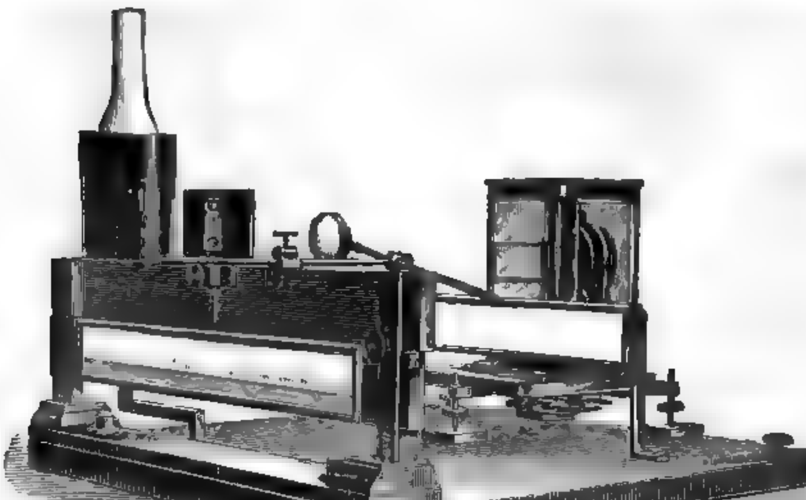
to supply the current at the recent Naval Exhibition, which, as we have mentioned, have been since purchased for the new station of the St. James's and Pall Mall Company at Carnaby-street. We likewise illustrate the well-known Siemens alternator with separate exciter, new types of which are also shown in the Machinery Department. From an historical point of view, there is nothing in the Exhibition likely to be of greater interest to electrical engineers than a small dynamo to be seen on Messrs. Siemens's stand in the Main Transept. This dynamo is within a few days of being a quarter of a century old, and is the first practical dynamo machine ever constructed, being the original machine made by Sir William Siemens, the forerunner of the innumerable progeny that now furnish the world with light and power. This dynamo was used in the Royal



Siemens Alternator.



Sir Wm. Thomson's Reflecting Galvanometer.



Siemens Testing Set.

Sir Wm. Thomson's Reflecting Galvanometer

The large central station dynamo and engine, direct-coupled, embodies the latest and best practice in the manufacture of continuous-current plant for supply of towns or districts. The dynamo is the largest size of the Siemens continuous-current type, with vertical two-pole field magnets, the armature being an immense drum laid rather than wound, with solid copper bars. Running at a comparatively slow speed of 350 revolutions a minute, this dynamo gives an output of 1,600 amperes at 120 volts, capable of supplying about 3,000 lamps of 10 c.p. It is coupled on the same shaft and bed-plate to a Willans and Robinson triple-compound engine, closed type, practically consisting of three separate engines driving upon one shaft, and supplied from the same steam-pipe, having its own steam separator. This central station set was one of several used

Institution and before the Society of Telegraph Engineers to furnish current for magnetising the large magnet.

In telegraphic and testing instruments Messrs. Siemens have a very fine and extensive show. Of these we illustrate several—the standard testing set, used for testing of all kinds, in the manufacture of cables, the testing of land lines or submarine cables, or electrical testing for resistance and capacity. The principal peculiarity of their instrument is the arrangement of the reflected beam of light from the galvanometer mirror. The lamp is placed beside the scale, its ray is taken by the lens and sent into the galvanometer, reflected from the suspended mirror upon an opal or frosted screen. This has two advantages—first, that the ray has a long distance to travel, and therefore shows delicate readings; and secondly, the spot of

light shows through the frosted screen, and is perfectly easy to observe without the observer's head coming into any awkward position. The constituent parts of this set, consisting of a Thomson reflecting galvanometer, lamp and reflector, lenses, and transparent scale, are shown separately. The telegraph station set of keys and resistances to be used with this galvanometer is also illustrated. This contains a resistance bridge (Siemens pattern), a set of comparison coils, branch coils, battery commutator, key, short-circuit switch, and peg commutators. The connections are permanent, and all necessary changes for testing cables and localising faults are made by simply altering the pegs. The galvanometer used for marine work is more strongly and compactly built and enclosed to stand transport. It is a dead-beat reflecting galvanometer, with tube arranged for liquid damping of the vibrations, as used for telegraphing and testing submarine cables and use on board ship. Two very different types of galvanometers are also shown. Tangent galvanometers (Obach's pattern), small and large size, have movable ring for the absolute measurement of powerful currents and E.M.F.'s; and Siemens's wire torsion electro-dynamometer, for the measurement of very weak currents. In this latter instrument there are two stationary coils (one removable) and a spherical movable coil. This coil is suspended by means of a very fine platinum wire at the top, and a spiral of fine copper wire at the bottom. Telephone currents can be readily measured by this instrument. A very convenient and useful set is that of the Siemens universal galvanometer, furnished with shunt, commutator, wire bridge, and resistance stopper, in mahogany case. It is a compact instrument, much used in ordinary work for taking resistances and finding the position of faults. The ordinary lineman's detector galvanometer used for all and sundry continuity tests, for telegraph or electric light wires, is too well known, even by non technical folk, to need more than mention.

Turning now to measuring instruments more definitely adapted for electric light work we have that most useful instrument, the Siemens standard electro-dyamometer. These are shown in various sizes to measure from 0·2 up to 500 amperes, and in portable form from 2 to 500 amperes. For measuring E.M.F. the potential galvanometer is a convenient and accurate instrument, measuring resistances from 0·01 up to 170 volts, or in larger form 0·01 to 1,700 volts. These are also made in portable form measuring 10 to 150 volts, or 20 to 300 volts. The ordinary Siemens voltmeter and ammeter is very largely used, especially on board ship for electric light plants. These are torsion instruments, read by turning the pointer till the needle is in equilibrium.

Several forms of Siemens's high-tension exploder for fuses and mines are shown, of which we illustrate two.

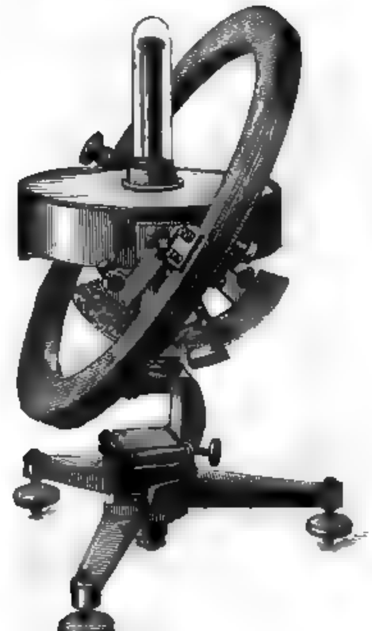
Telegraph Station Set.



Tangent Galvanometer—Dr. Obach's Pattern.

These are in reality small dynamos, giving, with vigorous rotation, 400 or 500 volts, capable of sending a strong spark through 20 or more fuses for simultaneous explosion.

The Hellesen dry cells, which are made and exhibited by Messrs. Siemens, are illustrated, showing the three usual types, and also the arrangement for house use in wall boxes. These batteries have an E.M.F. of 1·5 volt, and their internal resistance low—under 0·5 ohm for types Nos. 1 and 2, and under 1 ohm for No. 3. They can be used for closed as well as open circuit working, and are very constant with high recuperative power. The polarisation is very small, making them specially adapted for telegraphic, telephonic, and domestic service. They are very cheap, and mounted sections of cable is a complete set of the Siemens system of underground mains, both for low-tension and high-tension distribution, with street boxes uncovered to show method of connection—the high-tension connecting-box for concentric cable being specially interesting.

These exhibits are nothing if not practical, and one of the most practical, not being actual plant, will be the "portable testing set" on wheels. This is for the convenient use either of linesmen for street telegraph work, or for cable men laying mains for the electric light. It consists of a kind of covered van on wheels with handles for pulling, with door closing under lock and key, fitted inside with all the materials and instruments for careful testing.

give a large current for a considerable time, while being without liquid, are very clean and portable. For military field work, medical apparatus, and firing batteries they are much used. For household and hotel work they are fitted in wooden wall boxes to hold two or more cells.

At Messrs. Siemens's stand, besides the numerous instruments we have specially mentioned, are others well worth the attention of electrical engineers, to which we must do greater justice later. Two fine cases of cables show a large variety of telegraph, submarine, telephone, and electric light cables. Among these are specimens of the iron-sheathed concentric cables used on the London Electric circuits. But of more practical aspect than Three legs drop down to the ground and form a firm base for a reflecting galvanometer; a battery of 100 cells is stowed away at the back, and keys and resistances are conveniently arranged. The whole front is covered with a tarpaulin. The tester lets down a seat, lights his lamp, draws the curtain around him, and tests his mains. When finished he rapidly disconnects, packs up, and wheels his "testing van" to the next place of juncture.

Further practical articles are shown on the table for use of high-tension men. These consist of tools with handles covered with ebonite. Screwdrivers have their ordinary wooden handles covered ¼in. thick with ebonite; pliers the same beautifully covered with ebonite coating, and

safe to the hands of the worker. Chisels for cutting copper, and even spanners for unscrewing junction-pieces, are likewise coated with a thick covering of smooth and polished ebonite direct upon the metal. These tools should be found absolutely necessary where interference with live wires is required for station work.

In arc lamps Messrs. Siemens show fine specimens of projectors, not to mention an immense variety of lamp carbons.

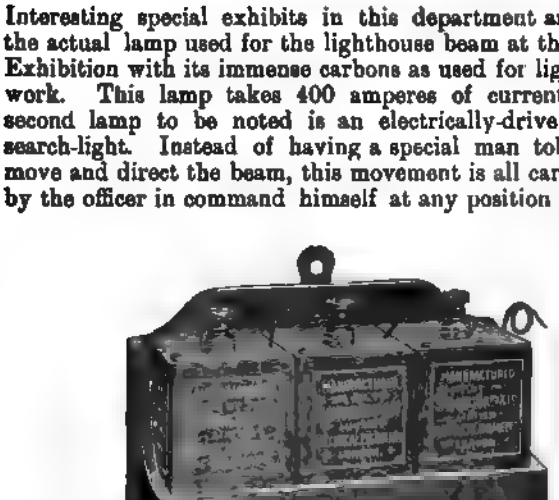
GIANT'S CAUSEWAY ELECTRIC RAILWAY CO.

The sixteenth yearly meeting of this Company was held at the Company's offices, Portrush, on Monday, Dr. Anthony Traill presiding.

The **Chairman** submitted the Directors' report for the year as follows: Your Directors beg to submit, for the approval of the shareholders, their annual report to December 31st, 1891, which completes the ninth year since the line was opened for traffic.

Hellesen's Dry Cells.

Interesting special exhibits in this department are, first, the actual lamp used for the lighthouse beam at the Naval Exhibition with its immense carbons as used for lighthouse work. This lamp takes 400 amperes of current. The second lamp to be noted is an electrically-driven ship's search-light. Instead of having a special man told off to move and direct the beam, this movement is all carried out by the officer in command himself at any position desired.



Hellesen's Dry Cells in Wall Box

The motion is brought about by magnets or motors, controlled by an ingenious switch, termed "bi-planer switch," the handle of which can move over contacts, up and down, or from side to side at the same time. The contacts control the light and movement of the projector entirely by slight movements of this one switch.

We have not yet exhausted the exhibits at Messrs. Siemens's stands; there is still their automatic electric block train signals; automatic defence mine exploders, besides the intricacies of the model electrically-lighted theatre in the Pompeian Court; demonstrations of the telephonic curves in the interior of the telephone; the experiments with the high-tension currents of 50,000 volts by means of their "electric sea-serpent," or cable shaped transformer, and the 50,000-volt transformer, which will be exhibited to the public after this week. Few exhibitors have taken such trouble to interest both the general public and electrical engineers, and their stands will certainly be one of the great attractions of the Crystal Palace Exhibition.

Your Directors are glad to be able to report another large increase in the passenger traffic in the year, the first-class passengers having increased to 9,292 from 8,943 last year, and 7,845 in 1889; and the third-class passengers having increased to 82,406 from 73,859 last year, and 56,822 in 1889—the total for the year being 91,698, with corresponding receipts, amounting to £2,830. 4s. 2d., as against a total of 82,802, with receipts £2,579. 19s. 5d. in 1890, and a total of £64,669, with receipts £2,338. 11s. 7d. in 1889. The goods and mineral traffic amounted to 181 tons, compared with 316 tons in 1890, and the receipts have been respectively £29. 1s. 5d. and £41. 8s. 11d. The receipts for parcels and miscellaneous traffic have diminished during the year from £77. 7s. to £19. 19s., so that the total receipts from the revenue account have been £2,895. 14s. 7d., as against a total of £2,698. 15s. 4d. in 1890. There has, however, been considerable increase on the expenditure side of the account, which shows a total of £1,945. 6s. 6d., as against £1,687. 12s. in 1890, and £1,732. 10s. 9d. in 1889. There is consequently a credit balance on the result of the year's working of £950. 8s. 1d., as against £1,011. 3s. 4d. in 1890, and £381. 18s. 7d. in 1889. This result has again fulfilled the anticipations of the Directors, and is traceable not only to the increase in the passenger traffic, but to the alteration made three years ago in the arrangements with regard to the goods traffic, which had previously been a constant source of loss to the revenue. It will be seen, on an examination of the above figures, that the ratio of expenses to receipts, which was 82 per cent. in 1889, and 62 per cent. in 1890, has been 67 per cent. in the past year. The value of electricity as a locomotive power, when generated by water power, as compared with steam, continues to be shown remarkably. The expenses of the electrical working amounted to £314 for 19,863 miles run, or less than 4d. per mile, while steam power cost £635 for 12,280 miles run, or 1s. 0½d. per mile. Your Directors regret the considerable increase in expenditure during the year, but they have found it necessary to refence the line for almost its entire length, to prevent accidents to cattle. They have also paid for the conversion of three waggons into cars out of revenue, and have spent a considerable sum in the renewal of the electrical apparatus, and, as the permanent way and steam engines have been kept in complete order, everything will be found in proper condition for the ensuing season. Your Directors regret that they are not yet in a position to offer a dividend to the shareholders, nor can they do so until the net revenue account is brought into a more favourable position; but they think it is evident from the great improvement which has taken place in the finances of the Company during the last two years, that the time is approaching when they will be able to do so; and they have to offer their thanks to their various supporters for their long-continued forbearance during trying times, not only for the Company, but for the country at large. The rapid increase in Portrush from year to year is most favourable to the prospects of the Company, as that town provides a constant stream of visitors to the Giant's Causeway and the intervening coast scenery; while tourists from distant parts, and the artisans from the manufacturing towns of Ulster, will add a large contingent, so long as the country generally is prosperous, and agitation is crushed out by firm government. Mr. Stuart and Mr. W. A. Traill are the directors who retire by rotation, and they are eligible for re-election.

Mr. Henry proposed, and **Mr. Stuart** seconded, the adoption of the report, which was passed.

Mr. C. M'D. Stuart and Mr. W. A. Traill, C.E., the two retiring directors, were re-elected.

NOTICE.

With this issue of the Paper is given a Supplement containing Portraits, taken from photographs, of **Mr. W. B. Esson, Sir Benjamin Baker, Mr. G. Binswanger, Mr. G. A. Grindle,** and **Mr. R. W. Wallace.**

Every reader should see that he gets this Supplement, and non-delivery with the Paper should be reported at the Publishing Office.

TESLA.

Although Prof. Ayrton in his presidential address has raised many points suitable for discussion, and although many questions of a practical character arise out of the meetings of the City and South London and the Central London Railway Companies, not to speak of those concerning the exhibition at the Crystal Palace, it is inevitable that we give the place of honour to our guest from across the Atlantic. Till a short time ago, Tesla was a name almost unknown to English ears. A few men had watched the announcements of his work in America, and Prof. S. P. Thompson, if we remember aright, introduced the name of the worker and his work in the borderland of science to the English public. But the man himself is now amongst us, and after his brilliant experimental lecture in the theatre of the Royal Institution on Wednesday the name will become as familiar as a household word. Geissler tubes have long been shown in the laboratory and the lecture-room, and many men have thought that in the dim and distant future something practical might arise from that root. De la Rue made many investigations; Spottiswoode, as will be remembered from his paper at the York meeting of the British Association, carried on the work; but perhaps above all others Crookes delved most deeply into this borderland of science. Now we have Mr. Tesla going many steps beyond his predecessors, mainly because he has called to his aid far greater "frequencies." The field of investigation has other explorers in Lodge, Hertz, J. J. Thomson, and we believe that the work done by Willoughby Smith ought not to be lost to view.

It was an excellent suggestion of the Institution to obtain the consent of the Royal Institution so that Mr. Tesla might expound his discoveries and show his experiments upon the spot which the immortal Faraday has made sacred to science. Hence it was that on Wednesday a brilliant gathering of members of the Institution met in the historic theatre to listen to the most recent and most wonderful discoveries in electrical science, and to witness experiments which to many of the audience undoubtedly came as one of the greatest surprises of the century. Mr. Tesla commenced his lecture by acknowledging his great indebtedness to Prof. Crookes, whose work first led him to undertake investigation into what at first sight seems a field rather barren of practical results. Perhaps, however, we are sometimes too anxious to see the end before the beginning is rightly grasped; still, we agree with those who consider blind experiment a waste of time. That is, the experimenter who, Micawber like, waits to see what will turn up, cannot be placed upon an equality with the one who has an object to gain and an end in view. It would be futile to attempt to describe Mr. Tesla's lecture or to discuss his investigations. That can only be done in a lengthy illustrated article, which no doubt will be duly forthcoming. It was perfectly evident, however, that Mr. Tesla's object is to obtain light, to supersede the present form of incandescent lamp by another form, to supersede the existing dynamo by another type. This is a very definite object, one that

G. BINSWANGER.

SIR BENJAMIN BAKER.

W. B. ESSON.

R. W. WALLACE.

G. A. GRINDLE.

deserves success, and one which, if it succeeds, will create a revolution in the industry. The scientific questions involved are of great interest, and will no doubt receive careful attention. Mr. Tesla kept his audience spellbound for two hours, and at the end of that time explained he had only performed about one-third of the experiments he wished to show. We trust that after all these years during which, as the lecturer said, the apparatus used has been common property, some practical development will be found to prove its utility.

CANTOR LECTURE—No. 2.

Prof. G. Forbes, in his second Cantor lecture on Monday last, discussed a number of interesting problems connected with distribution. Early in the lecture he referred to the term load factor introduced by Mr. Crompton, and stated that the definition of the term was indefinite. Mr. Crompton had made five distinct references, but Prof. Forbes would reduce the use of the term to three cases: (1) the machinery load factor; (2) the current load factor; and (3) the temporary load factor. It seems to us that (2) and (3) resolve themselves into one. The definitions given by Prof. Forbes are: (1) the ratio of the average current to the maximum current the machinery is capable of supplying, or

$$\frac{\text{average current}}{\text{maximum current of machinery}};$$

Similarly (2) is

$$\frac{\text{average current for period under consideration}}{\text{total current used in period}};$$

and (3) is

$$\frac{\text{average current for temporary period}}{\text{maximum current for that period used}}.$$

A brief review of the use of the multiple series method of distribution as in use at Temesvar and the Secteur Clichy in Paris, brought the lecturer to the important subject of alternate currents and transformers. A fairly exhaustive consideration was given to the use of transformers in each house and in sub-stations; the lecturer concluding with a description of some of the principal systems of mains in use.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CRYSTAL PALACE EXHIBITION.

SIR,—We have been looking anxiously for some specimens of electric welding apparatus in the exhibition in the Crystal Palace, but there are no signs thereof at present. We miss also the Parsons steam turbine. Is static electricity quite forgotten? A good influence machine shown in operation would be a great attraction. Those who can remember the beautiful machines in the Polytechnic in Regent-street will know what wonderful effects were produced from them. W.

THE ELECTROLYTIC LAW OF LEAST ENERGY.

SIR,—By the accidental omission of the words "the lowest," my letter, page 109, has become unmeaning. The extract should read:

"*At the electrode those ions are set free which absorb, in becoming free*, the lowest specific energy.—Yours, etc.,

J. T. SPRAGUE.

LITERATURE.

Electric Light Cables and the Distribution of Electricity. By STUART A. RUSSELL. With 107 illustrations. Whittaker and Co., London.

We have considerable pleasure in recommending to the notice of our readers Mr. Stuart Russell's book on "Electric Light Cables," which forms the latest addition to the "Specialists' Series," published by Messrs. Whittaker and Co.

Within the moderate compass of some 300 pages a large amount of useful information is contained; and although the treatment of conductors in regard to the *design* of a system of mains for any practical case can hardly be said to be complete, this little book should prove valuable to those electrical engineers who have not had experience in this branch of practical work.

After some introductory and historical remarks, Mr. Russell discusses the relative advantages of different materials for use as conductors of electricity, and he arrives at the conclusion, already well known in practice, that copper—soft or hard-drawn—and silicon-bronze are really the only materials suitable for practical work at the present time.

The relatively great cost of the insulation as compared with that of the conductor makes conductivity of supreme importance in the case of continuously insulated cables, but for bare overhead conductors the values of different materials may be fairly compared by tabulating the values of $\frac{\text{conductivity} \times \text{breaking stress}}{\text{specific gravity} \times \text{cost per ton}}$.

The question of economy in conductors next occupies Mr. Russell's attention, and he proceeds to discuss the particular case in which either a constant current or a variable current with a nearly constant pressure at the consumer's premises is employed. For this case Sir William Thomson gave the solution in 1881, and Mr. Russell shows how the solution is arrived at, and discusses the points which have to be taken into consideration when employing it in practice. He concludes the consideration of the economical aspect of design by a reprint of the tables given by Prof. Forbes in his Cantor lectures in 1885, and he very properly points out that the rise of temperature of the conductor and the loss of pressure in it must be carefully taken into account, and that these two considerations may make it advisable sometimes to use a smaller current density than that dictated by economy.

Mr. Russell gives a short account of Mr. Kennelly's experiments on the heating of conductors, and some useful tables based upon the results obtained.

After referring to the difference in the value of the ratio $\frac{\text{maximum current}}{\text{average current}}$ for direct and alternating currents, and to the bearing of this on the question of economy; and after printing Mr. Mordey's table of the virtual resistance of conductors for alternating currents with different frequencies, Mr. Russell proceeds to describe and discuss systems of distribution, with reference to the cost of the mains, and the greatest distances to which electric energy can be supplied from a central station.

Some very interesting chapters then follow on the construction and jointing of different forms of conductors, on the insulating materials employed, and on the considerations which determine the thickness of insulation in different cases, on lead-covered cables, on junction and terminal boxes, etc.

The important subject of testing of cables for conductivity, insulation, and mechanical strength is next dealt with, and the conditions under which such tests should be carried out to make them of any real value carefully described, and descriptions of the ordinary methods employed in practical testing are given.

A chapter on internal wiring next follows, in which Mr. Russell deals pretty fully with the prevention of fire risks, permissible loss of pressure in house wiring, and with practical methods of wiring and fitting an installation in a safe and durable manner.

We come then to overhead lines, with a discussion on their supports, insulators, lightning protectors, and on the calculation of the stresses in the lines and bearer wires.

We thoroughly agree with Mr. Russell that the Board of Trade rule, which insists on a factor of safety 6 for a wind pressure of 50lb. to the square foot, is altogether unnecessary, and we doubt whether there is an overhead line in the world conforming to this (in our opinion) absurd rule.

The remainder of the book is occupied with descriptions of various systems of laying underground mains and of the conduits for carrying them. The principal systems in use are clearly described and well illustrated, and form an interesting account of the present methods of putting down underground mains.

While we think Mr. Russell's book both a useful and interesting one, we must point out one or two points in which we think he is in error, and which we hope to see amended in future editions. To take the most important first, we are distinctly at issue with Mr. Russell when he decides that the cost of the energy wasted in conductors should not include an amount for interest and depreciation on plant. Loss of pressure and waste of energy cannot be considered separately in the way Mr. Russell apparently does. He says, on page 20, "In the design of a station, when the number of dynamos has been decided upon, it is usual to make them of such capacity that they can together supply current for the maximum demand plus an allowance for reserve, and that each can supply its current at such a pressure as will provide for the loss in the longest feeders which can be required in the district, and then to provide means for reducing the pressure as required by lowering the speed or adjusting the field strength. . . . This being so, it is evident that as long as no mistake has been made in the estimate of the maximum pressure required at any station, the first cost of the dynamo and machines is not affected by a variation in the amount of energy wasted in the conductors."

Now, if the dynamos are required to give a higher pressure than is required at the consumers', it means, of course, that their output and that of the rest of the plant is greater, on account of the resistance of the mains, in the ratio of the pressure at the station to that at the consumers', than it would be if the conductors were of such size that their resistance was negligible.

The extra output is directly necessitated by the fact that the conductors are of a particular size, and the interest and depreciation on the extra amount of plant required should be debited along with the cost of the energy wasted in the conductors, when we seek to proportion the conductors for maximum economy or minimum total expenditure per annum.

On page 51, Mr. Russell says that in the series system the speed of the engines and dynamos is reduced with the load, so that the work done per stroke is kept constant. In the Brush and Thomson-Houston systems, which operate the great majority of arc lamps in the world, it is customary to employ automatic regulators, which shunt the field magnets or move the brushes on the commutator, and we think that regulation by means of the governor (whether by hand or automatic arrangement) is but comparatively seldom used.

We notice that, while Mr. Russell uses the notation of the differential calculus (on pages 18, 19, 20, for example), he prefers lengthy expressions and reasoning to using the notation of the integral calculus. On page 24, for example, in place of the expression for the square root of the mean square of the current, we think he might write

$$C = \sqrt{\left\{\frac{1}{T}\int C^2\, d\, t\right\}}$$

with advantage, or as Dr. Rasch has done

$$C = C_{max}\ \sqrt{\left\{\frac{1}{T}\int i^2\, d\, t\right\}}$$

where C_{max} = max. current of the year considered.

$$i = \frac{\text{current at any instant}}{C_{max}}$$

Again, on pages 107, 108, and 109 we think

$$R = \frac{s}{2\pi l}\int_d^D \frac{d\,r}{r} = \frac{s}{2\pi l}\log_e \frac{D}{d} = \frac{s}{2{\cdot}728\, l}\log\frac{D}{d}$$

very much simpler than performing the integration by summing the series as Mr. Russell does; and the engineers who know that

$$\left(1 + \frac{1}{x}\right)^x = e \text{ when } x = \infty$$

know also that $\int \frac{d\,r}{r} = \log_e r$, while those who have to take on trust the value of e, may just as well be given the value of the integral at once.

At various parts of his book Mr. Russell writes

$$R = R_0 \times 1{\cdot}0021^t$$

when R = resistance of copper conductor at t deg. F.
R_0 = resistance of copper conductor at 0deg. F.

and we think the simpler, and as we believe more accurate, formula

$$R = R_0\,(1 + 0{\cdot}0021t)$$

would have been employed with advantage. We may point out that Matthiessen's results do not bear out Mr. Russell's formula so well as the simple one. Matthiessen's results were given by the formula

$$R = \frac{R_0}{1 - a\,t + b\,t^2},$$

which gives a curve of R and t at first concave towards the R axis, but at a quite low temperature there is a point of inflection, and the curve bends over and is concave towards the axis of t.

NOTES ON THE MANAGEMENT OF GAS ENGINES.

(Extract from "First Principles of Electric Lighting.")

The following notes are mainly intended for those who, although not mechanics or engineers, may find themselves in charge of a gas engine—a source of power the use of which is extending by leaps and bounds. The management of these engines is really a simple matter; at the same time, they will not run without some little care and attention. The writer has had many years' experience in the management of gas engines, and it is hoped that these notes will be of assistance to those for whom they are written.

Although many of these notes are applicable to various makes of gas engines, they especially refer to Crossley's "Otto" (slide-valve type) and the new Crossley "Otto," hot-tube ignition (without slide-valves), each being dealt with separately.

Starting.—See that everything is *clean* both inside and outside, that the water is properly supplied to the cylinder jacket, and that the moving parts are free and well oiled; then light the burner at bottom of chimney and adjust the inner light, which should be turned as high as possible without causing it to smoke.

Next move the governor to its middle position, and keep it there by means of the "stop" provided for this purpose, so that it can act on the gas-valve. The "stop" should disengage itself as soon as the engine begins to run.

How to Turn the Flywheel Easily.—To facilitate turning the engine by hand at starting, the roller on the exhaust valve lever may be moved further out so as to engage the *second* cam (or projection) on the shaft, the pin that secures it being changed to the other side of the roller for the moment, but when the engine has started *the roller must be replaced and secured* again so as to be moved by one cam (or projection) only as before.

In the vertical type of engines the exhaust roller is lifted *upwards*, and held there by the taper pin whilst starting; when started, the pin is pulled out and the roller drops into its working position and requires no securing. In the smaller sizes of engines no relief cam is required.

Quantity of Gas at Starting.—To prevent *too much gas* being given while turning by hand at starting (which often prevents ignition), close the tap *behind the bag* until the engine begins to work; if the bag be emptied before the engine has started, gas must be again admitted to fill the bag and another attempt made. After a short time a

position may be found in which to place the tap so as to admit the gas slowly, turning it *full on* as soon as the engine is fairly started.

Some engines being troublesome to start from this cause, a small by-pass tap (the main tap being closed) will be found very convenient in starting, or a gas pressure regulator can be fitted between bag and gas main. These matters being attended to, open the engine gas tap, turn the flywheel as quickly as possible a few times by hand, when the engine will at once begin to work. *It is useless pulling the engine slowly round.* It only wastes strength and fails to start the engine.

Difficulties in Starting.—If the engine should take long to start without apparent reason, examine the exhaust-valve, and ascertain whether any dirt or other cause prevents it closing tightly. If this valve is not at fault, look to the *gas supplies* at every point.

Sometimes water, by accumulating in the exhaust-pipe, may cause stoppage. A small hole or a tap at the lowest point of the pipe will prevent this.

If all attempts at starting the engine fail, do not tinker with it, but *get a man from the makers* to attend to it, carefully noting what he does and asking him to explain the cause of the difficulty, but if ordinary care be taken, and these instructions carefully followed, no serious difficulty is likely to occur.

Lubrication.—The two principal parts requiring lubrication are the slide-valve and the piston. Self-acting oilers are provided for both. These should deliver from four to twelve drops a minute to the cylinder, according to size of engine, and two to the slide-valve. See that they drop the oil as intended, as if allowed to run dry the surfaces will "cut" and the slide-valve will require to be "faced," or the duplicate valve, etc., put on before the engine will work again. The interior of the cylinder may also be seriously damaged.

Oil all the other bearings three or four times a day in the usual way, and see that none get too warm by being too tight or too dry.

Oil.—It is advisable to use oil supplied by the engine-makers. The price is rather higher, but it is worth it, and inferior oils always lead to difficulty from dirt left in the cylinder and ports, causing irregular working and sometimes a total stoppage. *The quality of the oil is a most important matter.*

Regularity of Ignitions.—Always see that an ignition occurs *each* time the small gas-valve is opened by the governor. If it does not, the cause may be dirt in the slide-ports, or want of regulation of the slide lights, or wear of slide-valve. The gear which opens the gas-valve may also, after a time, wear a little, and thus decrease the supply, causing loss of power or stoppage. If so, it is easily adjusted.

Water Vessel and Cooling.—Never work the engine without water in the jacket of the cylinder. The water vessel must be kept full by a ball tap.

See that the circulating pipes are acting. The pipe from top of cylinder to water vessel should slope upwards at every point, being nowhere exactly horizontal or sloping down. The cylinder should not get very much hotter than the upper part of water vessel. If the engine is exposed to frost when not working, burn a gas light under the cylinder, *to keep the water from freezing*, or if more convenient the cylinder may be emptied. Neglect of these precautions may cause the bursting of the cylinder jacket owing to ice forming.

Exhaust-pipe.—Never turn the exhaust-pipe into a flue, chimney, or drain, lest an accumulation of gas may accidentally take place and damage be done. Lead it to the open air, keeping it clear of all woodwork by 6in. or 10in., as it gets very hot when in use.

Cleaning Slide-valve.—Remove the slide-cover, take out the slide-valve, and clean all the passages in the various parts, especially the small hole in the slide-valve *leading from one* of the square ports to the small hole through valve just above the port. This hole, not being visible, often escapes attention. The small hole in back plate leading into cylinder also requires thorough cleaning to its full depth. After cleaning and freeing all the parts from grit, oil the surfaces thoroughly and replace the slide and cover, which must be adjusted as follows: Place the split stops on screw studs, then the springs and milled nuts, tighten up the springs by means of the milled nuts, move the engine round a few turns by hand, then tighten up the small nuts on the split stops with the short spanner provided for the purpose, and having afterwards slackened the milled nuts the slide will be ready. Small tools for cleaning are sent with each engine.

Changing Slides. — Difficulty in starting will occur after a time from slight wear of the surfaces of the slide-valve, or from injury from want of oiling. When this occurs the best plan is to send the whole set—viz., back plate, slide, and slide-cover—to the makers, as they will then be properly faced up, an operation requiring considerable skill and practice.

In the meantime the spare set of slides must be brought into use, taking care to clean out the tallow and white lead, not omitting the small hole mentioned in "Cleaning Slide-valve." The gas fittings must be carefully removed from the damaged set, and placed in the spare set. When placing the back plate on cylinder end, see that no dust or grit is on the surfaces, or the screws will not draw them into close contact, and a "blow-by" will result. See also that the screw-driver used raises no "burr" on the screwheads which might project above the surface of back plate; the slide-valve and cover are placed in position as described in "Cleaning Slide-valve."

The Piston.—The piston should not be taken out unless cleaning or new packing rings are needed. When it is taken out, scrape everything thoroughly out that may be left at the back of cylinder, but if the oil and gas are good nothing will be found. The crank-pin brass has alone to be uncoupled to draw the piston.

If it be necessary to fit new rings owing to an escape by the piston, only change one ring at a time, commencing at the back. The joints of all the rings should be at the bottom side of the piston. To draw the piston is easy, to put it back, turn it upside down, and when in the cylinder turn it round so as to bring the figures on connecting-rod to the top. Be careful to see that the small steady-pins in piston ring grooves fit into the slots in the rings, or the rings will get broken.

It requires some practice to readily replace the piston, and unless really necessary it should not be withdrawn when doing it, have patience, and do not use force.

In 16-h.p. engines the cylinder should be cleaned out inside once a week, *not by removing piston*, but by scraping the dirt out through the cover over exhaust-valve, which is made large enough to admit a youth's arm.

The Governor.—The governor performs two distinct functions—it cuts off the gas both when the proper speed is exceeded and when the engine stops. See that these are properly performed, and that the gas-valve shuts correctly, lest running away or waste of gas accidently follow.

The Gas-valve.—This only requires a little "grinding in" at long intervals. See that the stem is clean and free from stickiness, and that the spring causes the valve to close sharply.

The Air-valve.—This again requires little attention, and the remarks *re* gas-valve apply equally to this.

The Exhaust-valve.—This valve requires close attention if the engine is to work regularly and efficiently, it being exposed to intense heat and to the cutting and corrosive action of the exhaust vapour. If this valve does not close tightly, not only is there a large waste of gas into the exhaust-pipe, causing annoying explosions in the same, but the remainder of the mixture of gas and air is not properly compressed, causing great loss of power when exploded, and often missing exploding altogether, so causing further waste.

To test the condition of this valve (although it often makes itself known by a difficulty in starting the engine), turn the engine by hand without moving the exhaust-valve roller from its normal or working position. If the valve be in good condition, great resistance will be felt on the in-stroke of the piston during which the compression takes place, and if the flywheel be suddenly released, the engine

will make one or two revolutions backwards, owing to the reaction of the compressed air. If, however, the valve be leaking, the air can be heard "blowing through" it, and little or no resistance experienced in turning the engine by hand.

Owing to the neglect of this valve, from want of knowledge, a considerable amount of gas as well as power is lost by most gas engines, and is the cause of the gradual increase of the gas bills, although the work remains practically the same. To repair the exhaust-valve, remove the cover and also the connections at end of spindle, lift up the valve and smear the seat with a little emery and oil, and grind in by giving the valve a circular motion. To facilitate this operation, use a piece of iron rod screwed at one end to fit hole in valve head and squared at the other to fit an ordinary brace or stock; continue the operation until the edge of valve and valve seating show that the parts come into contact all round. When this is the case, wipe off, replace the valve and attachments, put on the cover, and screw down securely, first placing a little black-lead and oil on the threads of nuts and bolts, as the heat is apt to make the nuts "set fast."

Adjustment of Exhaust-valve Lever.—There should be nearly ⅛in. play between the roller on exhaust-valve lever and the body of the cam *when not lifting*, to ensure the shutting of the exhaust-valve. The operation of grinding in (above mentioned) tends to lower the valve, and so reduce this distance.

Protection from Dust.—Keep the engine clean and free from dust and dirt, taking particular care that none can fall on to the slide from roof or ceiling.

THE BERLIN UNDERGROUND ELECTRIC RAILWAY.

The Electricitäts Gesellschaft of Berlin, says the *Eisenbahnzeitung*, is not the only company which has applied for a concession for an underground electric railway in the German capital; but it is the company which seems to have the best chance of obtaining the same. The scheme for such a railway in Berlin has been accelerated by the success of the underground electric railway in London. The company named proposes to construct two lines crossing each other at right angles, and following the main traffic of the city. These two lines would divide the town into four quarters, which would again be connected by two concentric lines, with stations at the points of crossing. The main line, N.-S. (Friedrichs Strasse section), under the Chaussée, Friedrichs, and Belle-Alliance Strasse; and the E.-W. line (Leipziger Strasse section), below Landsberger, Konigs, Leipziger, and Potsdam Strasse. The crossing point of the two tunnels is situated at the cutting of Friedrichs and Leipziger Strasse. If from this point two circular lines, 6,000ft. and 12,000ft. apart, be drawn, we have the course of the two circular lines, but the outer one must be considered one for the future. On the other hand, the remaining lines are to be completed in two years. The lines will be distinctly separated, as the tunnels lie above each other. At the terminal points the metals would run into a loop, so that the train, without actual shifting, will run from one tunnel into the parallel one in the opposite direction. Thus there can be no collision of trains running in opposite directions.

The method adopted by Mr. Greathead in the construction of the City and South London line will be followed, iron tubes being used, whereby the tunnels will be impervious to their greatest enemy—ground water. For the tunnels, oval cast-iron tubes are to be used ⅛in. in thickness, 11ft. high and 9·6ft. wide at the bottom, and which will lie at a depth of from 20ft. to 45ft., or about 6ft. below the bottom of the River Spree. Each train will be composed of three cars, like the ordinary tramcars, having two pairs of wheels at each end, and being open from end to end, and affording seats for 40 persons. The train will be drawn by an engine, an electric locomotive of simple construction, as it will not generate but only utilise the electrical energy. The engines are to be equipped with slow-speed electro-motors, and the necessary brake and regulation apparatus and afford room for the driver and assistant. The trains are to be run every three minutes with a speed under 16 miles an hour. The difficult problem of platforms has been happily solved by placing them in the space between the two parallel tubes, about 30ft. apart. These platforms will be composed of several iron tubes, and access will be gained from the street by elevators or steps, with waiting-rooms above. The lifts will hold 50 persons. At the crossing stations there will, of course, be two platforms, one above the other, and communicating. For the section to be built first, the Friedrichs Strasse line, 14 stopping places are contemplated, and with the speed indicated, and allowing for stoppages, the journey would occupy 20 minutes. The total length in both directions would be about 13 kiloms. (8 miles), and the cost is estimated at £600,000.

MODERN APPLICATIONS OF ELECTRICITY TO METALLURGY.*

BY G. C. V. HOLMES, SEC.I.N.A.

(*Continued from page 94*).

It has been stated that in practice the difference of potential between the terminals of any one tank is between one-half and one-quarter of a volt. Taking, however, the figure of two-thirds of a volt as a standard, and briefly examining the cost of producing the current, at a consumption of 2·24lb. of coal per indicated horse-power per hour, one ton of coal should give exactly 1,000 i.h.p. for an hour. Assuming the combined efficiency of engine and dynamo to be 75 per cent., a figure well within the limits of the best practice, the above engine power should give us 750 e.h.p. or 750 × 746 = 559,500—watt hours. Supposing, for the sake of simplicity, that the whole of the work is done in one huge tank, the conditions of which allow the current to be passed through with a difference of potential of two-thirds of a volt. There would then be a current of 559,500 × $\frac{3}{2}$ = 839,250 amperes for an hour. Now, referring to Table I., a current of one ampere for a second can deposit 0·0003307 grammes of copper; therefore the amount deposited by the same rate of current in an hour = 0·0003307 × 3,600 = 1·19052 grammes, and therefore the current of 839,250 ampere-hours can deposit 839,250 × 1·19052 = 999,140 grammes, or almost exactly one ton of copper can be deposited with the consumption of one ton of coal under the assumed conditions. Of course, for the purposes of the calculation it would have done equally well to have taken the conditions which obtain in the actual process—namely, a much higher E.M.F. and a correspondingly reduced current, so long as we kept the product of amperes and volts constant.

Thus, if an E.M.F. of 100 volts had been selected, a corresponding current of 5,595 ampere-hours would have been taken, and while the copper deposited in each tank would have been $\frac{1}{150}$th of what it was in the first case, the E.M.F. would be sufficient to pass the current through 100 × $\frac{3}{2}$ = 150 tanks instead of one. It need hardly be mentioned here that these figures are only given as an illustration, for in working much smaller currents are dealt with.

To the cost of fuel necessary for producing the current has to be added that of labour, maintenance, stores, and that of refining copper matter, or rough copper, up to the standard pitch of purity, and also that of casting the anodes. The actual cost of producing a ton of pure electrolytic copper varies also somewhat with the design of the plant and the care that is spent in maintaining it. If the current be allowed to run to earth, if conductors of scant area, and if dirty contacts are used, if the electrolyte be not maintained in proper condition, if very impure anodes are employed, and if the current passed through the tanks be so dense that a high E.M.F. is necessary, the cost of electro-refining copper may easily be made ruinously expensive. But if the conditions are made and maintained favourable, as they can be with moderate care, the cost should not exceed from £3. 10s. to £4 per ton, and has in some instances worked out much lower. If due care be exercised in the selection of the brand of copper to be refined, this cost may easily be more than covered by the value of the gold and silver recovered from the sludge in the bottom of the tanks.

Treatment for Rendering the Deposited Copper Suitable for General Use.—The copper deposited in electrolytic refineries, though chemically pure, is of a crystalline character, and possesses but little cohesive strength. It is therefore, in its deposited condition, quite unsuitable for the manufacture of goods, and is, in fact, only used for the manufacture of high conductivity wire for electric purposes, and before being drawn into wire it has to be melted, cast into ingots, forged, rolled,

* Paper read before the Junior Engineering Society, Jan. 15.

and cut into strips. If the copper could be deposited in a tough, dense, and reguline condition at the same time that it was being refined, a great saving of expense would result.

The Elmore Process of Copper Deposition.—Numerous experiments were carried out from time to time with the object of attaining the desired end, but none of them resulted in anything like practical success until Messrs. Elmore invented the beautifully simple process of continuously burnishing the copper while it was being deposited, without removing the cathode from the bath.

The manner in which this is done may be described as follows: A mandrel of iron, or preferably of copper, is mounted on insulated bearings in the tank or bath, and a burnisher consisting of a small prism of agate is caused to travel, like the cutting tool in a lathe, along the surface of the mandrel in a direction parallel to its axis. While the current is passing, the mandrel is caused to revolve by wheel and chain gearing. The anodes are arranged at the sides and bottom of the mandrel, and as near the latter as can be conveniently managed. If the mandrel is of iron it must, before being mounted in the bath, be covered with a thin deposit of copper in a cyanide of copper bath, otherwise the surface would be attacked by the free acid in the bath. As the copper is deposited on the revolving mandrel the burnisher presses with even but gentle force on the surface, and breaks down the crystalline formation, converting the deposit into a dense, reguline metal of greater specific gravity than ordinary sheet copper. The speed of travel of the agate burnisher is so arranged in relation to the depositing power of the current that, on the average, a layer of copper of not more than $\frac{1}{500}$in. in thickness is deposited in the interval between two successive passages of the tool over a given spot.

The tanks are arranged end to end in double rows, and between two rows is placed the line of shafting which drives the chain and wheel gearing by which the mandrels are rotated. Between the same two rows is also placed parallel to the axes of the mandrels a piece of shafting as long as the row, which is propelled alternately backwards and forwards for a distance equal to the length of the longest mandrel in the tanks, by a screw, resembling the screw of a lathe, and which is placed between the pair of tanks at one of the ends of the double row. This long piece of shafting carries on slide-bars, resembling the slides of a lathe, rests, to which are attached the burnisher-holders. If the mandrels are of small diameter two or more of them can be mounted in the same tank, the object being to expose approximately the same surface of cathode in each. The current passes away from the cathode through a copper brush—somewhat resembling the brush of a dynamo—which bears against the revolving surface of one end of the mandrel. The above operations are purely automatic and go on night and day. One attendant can attend to 50 or 60 tanks, and thus the process, in addition to its other advantages, has the merit of being very economical of labour.

One of the great advantages secured by the use of the burnisher over and above the superior quality of the metal obtained is that the current density per square foot of cathode may be from three to four times that made use of in electro-refining, or in ordinary electroplating. A current of 20 amperes per square foot is commonly made use of, and even 28 amperes have occasionally been employed with perfect success. The author need hardly point out the saving to be effected in the first cost of buildings, tanks, and gearing by the power thus conferred of depositing at a rapid rate. A current density of 20 amperes corresponds to a rate of deposit of nearly 9lb. per square foot of cathode per full week of 168 hours.

As in all electric processes, so in this, the greatest care must be taken to ensure that there is no loss of current to earth—such as would be brought about by leaky tanks—and no unnecessary outside resistances—such as would be caused by imperfect contacts where the branch conductors are joined to the mains. All the observations regarding the means of ensuring a perfectly pure copper deposit which have already been made with reference to electro-refining apply equally here.

It is absolutely essential that in cases where perfect continuity is desired in the metal deposited there should be no interruption to the current. The density of the current may be varied without producing a severance of the continuity of the metal, but if the current were stopped altogether, and oxides were present on the surfaces of the anodes, there would be generated a back current in each tank which would result in the partial oxidation of the surface of the cathode, and a break in the metallic continuity when the current was put on again would be the consequence. Even if there were no back current the surface of the cathode would oxidise in time, for it is well known that the free sulphuric acid in the bath would attack the copper in the presence of air, and in consequence of the rotatory motion of the mandrels, it is highly probable that a considerable portion of air is drawn into intimate contact with the surfaces. Hence, in cases where metallic continuity in the finished product is imperative, as, for instance, in high-pressure steam-pipes, or in tubes which have afterwards to be drawn down to a smaller diameter, it is essential that means be adopted to render the current continuous.

When the metal has been deposited to the required thickness, the tank in question is cut out of the circuit, the mandrels removed from it, and the liquor run out into a settling-tank where the sludge separates out. The copper tube which has been formed on it is then removed in one of several ways. It may either be expanded off by superheated steam if deposited on an iron mandrel, as copper expands more per lineal unit, when heated, than does iron; or it may be put into a machine and be subjected to the squeezing action of rollers which gradually travel along its surface, the effect being to slightly enlarge the diameter of the tube, and thus enable it to be drawn off the mandrel. If the mandrel, however, be of copper, the tube requires neither heating nor rolling, because the first film of copper that is deposited can, by a most ingenious contrivance, be separated from the body of the mandrel while still allowed to adhere at the two ends. When finished, the two fixed ends are cut off in a lathe, and the tube can be easily withdrawn.

(To be concluded.)

EFFICIENCY AND COST OF ELECTRIC LIGHT.

An admirable lecture was given before the Peterborough Scientific Society last week on the above subject by Mr John C. Gill, A.M.I.C.E., city engineer and surveyor, of Peterborough. The lecture was fully illustrated by lamps and batteries lent by the India Rubber Company, of Silvertown.

Mr. Gill first explained in an explicit manner the efficiency of the electric light as compared with gas in lighting power. The official unit of light is the candle-power, the light of a standard candle, six to the pound, burning 120 grains of spermaceti wax per hour. The lecturer here explained combustion of gas at burner, showed and explained the glow lamp, and how the filament is made incandescent by passing a current of electricity through it. Dr. Julius Thomson, of Copenhagen, has made some careful tests of the energy consumed in producing light by sperm-candle, oil, and gas, and gave the result as 12·28 foot-pounds per candle-power per minute, and as this confirms the results of other independent tests where electricity was also used, the mechanical equivalent of artificial light, taken for these calculations, was 12 foot-pounds per candle per minute. In producing light by coal gas and electricity, we start at the same place—the coal, and finish at the same place—the light. The energy taken from the coal at the commencement, and that delivered in light at the end, can be compared. The last Board of Trade return on the manufacture of gas in the United Kingdom shows the total quantity of coal used in 1890 amounted to 10,240,000 tons, and this produced 103,100 millions of cubic feet of gas. This gives an average of 10,066ft. of gas for each ton The total heating power of 1lb. of average coal amounts to 14,320 units, one English thermal unit being equal to 772 foot-pounds of work. The average quantity of coal used in making one cubic foot of gas is, from the foregoing figures, ·222lb., and allowing five cubic feet to give 16 c.p. for one hour, we get 11,520 foot-pounds energy in light from each 1·11lb. of coal. But each 1·11lb. of coal contains originally 12,069,412 foot-pounds of energy, so only ·095 per cent. of the mechanical energy in the coal is utilised, or, it may be said, the efficiency of coal-gas is ·095 per cent.

Turning to lighting by electricity, coal is used in a very different manner to produce the same effect. But the efficiency of the light as compared with the energy in the coal may still be worked out. The average consumption of ordinary coal to drive the dynamos in central station lighting may be taken at 2½lb per horse-power hour. Each horse-power at the engine therefore absorbs 35,800 units of heat per hour, or 27,637,600 foot-pounds of work. Now, an incandescent electric lamp of 16 c.p. requires 60 watts of electricity per hour. The mechanical equivalent of one watt of electric current being 44·2 foot pounds per minute, the 16-c p. lamp uses 159,120 foot-pounds per hour. One h p. would therefore supply 12·4 lamps each of 16 c.p. for one hour, or a total of 198 candles, which at 12 foot-pounds per minute would have a mechanical equivalent of 142,560 foot-pounds per hour. But it has been seen that to get this energy at the lamps coal is used at the boiler, the energy of which amounted to over 27 million foot-pounds, and working it out exactly the efficiency is ·516 per cent. The respective efficiences are therefore coal-gas ·095 and electricity ·516 per cent., the proportion being as 1 to 5·4. Both processes seem at first sight to be exceedingly wasteful, as by the better of them there is less than 1 per cent. of the energy in the coal utilised, while more than 99 per cent. is wasted. But the great object of the comparison was to show that electricity will give five times more light than gas from the same amount of coal, or, to put it in another way, 1lb. of coal will give five times as much light when used through a steam engine and dynamo as when made into gas. This fact must in course of time tell in favour of electricity.

Mr. Gill then proceeded to explain the electrical units, watt, ampere, and volt, and remarked: The time is coming when every ordinary mind will have a fixed idea of a watt of electricity, just as it has now of a gallon of water or a yard of ribbon. For the present purpose it is sufficient to bear in mind that one watt is 1-746th part of 1 h.p. A 16-c.p. lamp requiring 60 watts per hour of electricity, for 1,000 watts we should have 265 candles. Taking a flat-flame gas burner to give 12 candles for every 5ft. per hour consumed, we have 2,400 candles for each 1,000ft. of gas. The ratio between the lighting power of 1,000ft. of gas and one kilowatt of electricity is therefore

as 9 to 1, and to be of equal cost, light for light, the price of one kilowatt of electricity should be ⅑th of the price of 1,000ft. of gas. With the price of gas at 3s. 4d. per 1,000 cubic feet, as in Peterborough, the price of electricity to supply the same light at the same cost should be 4½d. per kilowatt-hour or Board of Trade unit. At Newcastle-on-Tyne the price is 4½d. per kilowatt, and therefore electricity is sold at Newcastle at the same cost, light for light, as gas at Peterborough. But it is hardly fair to want the electric light supplied at the same price as gas. It is so much brighter, purer, cleaner, healthier, and safer that its market value is higher. Thus we find that there is a great and constantly growing demand for electric light in Bradford, where it is sold at 6d. per kilowatt, although the price of gas is only 2s. 3d. per 1,000ft. Electric lighting has large collateral economic advantages when compared with gas. Enquiring whether the present price of electric lighting will be maintained, or whether there is any prospect of its being cheapened, the lecturer gave the reply with the greatest certainty that it will become much cheaper than at present. The day of experiment is passed, and the permanent electric lighting plants now erected are amongst the most efficient of machinery. But there is a monopoly in the manufacture of the glow lamps which keeps up the price. Two years hence the Edison-Swan patents will expire, the manufacture will be open, and the cost considerably reduced. Another reason why we may safely predict a lowering in the price of electric lighting is that the interest on capital and the maintenance expenses of a large central station plant are just as heavy when supplying only one-third of their full capacity of lamps as they are when running with a full load. This is just what is happening now, and the electric lighting industry is passing through that season of heavy outlays and small returns through which every new industry has to pass. It was exactly the same with gas when first introduced, and gas companies now pay good dividends. As with gas, so with electric light – the greater the demand the cheaper the supply. There can be no denying the fact that the past year has been one of extensive progress in electric lighting. The Act of 1888 made successful lighting by electricity supply companies possible, yet there are already companies registered whose authorised capital amounts to £5,300,000. This will compare favourably with any other new industry, and it must be borne in mind that this sum of five and a quarter millions devoted to electric lighting is independent of the electricity supply works established in many towns by the local authorities.

A vote of thanks was cordially given at the close.

CANTERBURY.

The following is the report of the committee selected to report upon the drafts of agreement and deed of transfer submitted to the Canterbury Town Council by the solicitors to the Brush Electrical Engineering Company, Limited:

The committee having had under consideration the drafts of the agreement and deed of transfer submitted by the solicitors to the Brush Company beg to report that in the opinion of the committee one of the first and most important points to be assured is the stability of the company to which the transfer of the Canterbury Electric Lighting Order, 1891, is to be made. The original proposition was that the Council should transfer the order to the Brush Company, or to a local company to be formed in all respects to the satisfaction of the Council, but in any event it was understood that the capital was to be £50,000, for which the Brush Company was to be answerable, it being proposed that a sum of £15,000 should be called up to commence with. The draft submitted to the Council provides for a transfer of the order to the Canterbury Electricity Supply Company, Limited, a subsidiary company formed under the auspices of the Brush Company and at present existing only in name, having no capital subscribed except seven shares taken by the seven subscribers to their articles of association, who are officers and employés of the Brush Company. The draft provides that the capital of the Canterbury Company shall be increased to £50,000, but it is proposed to start with a subscription of £15,000 only, and it is provided by the agreement that if there is a failure to obtain subscriptions to the extent of £15,000 before June 1, 1892, either party to the agreement may determine it. It is scarcely necessary to point out the difference in point of stability between a company with £50,000 subscribed and £15,000 paid up, and a company with a subscribed capital of £15,000 fully paid up. Having regard to the importance of dealing with a company of stability, your committee consider that if this transfer is to be made to the Canterbury Company, the Council should have safeguard by the Brush Company's guarantee to the extent of the £50,000 capital, so that the money may be called up and may be forthcoming as required.

It was stated on the original proposition that the Brush Company would commence the work of electric lighting directly a transfer of the order was made, but the present draft makes the whole transactions depend on the raising of £15,000 by this Canterbury Company. If, however, the precautions suggested above as to transferring to a stable company are adopted, this difficulty disappears.

The committee further consider that the compulsory area of supply should be increased by the inclusion of Bridge-street, Broad-street, and Palace-street.

With reference to the powers for the Council to repurchase the undertaking, your committee consider that no claims should be made for compulsory purchase, and provisions are required that at the expiration of 42 years the Council may repurchase under the terms contained in the Electric Lighting Acts.

No limitation is contained in the draft as to the amount of dividend which the company taking over this order may make, but your committee consider that it is most important that there should be some limit, and propose that after the company has received a cumulative dividend of 7 per cent., one-half of the excess profit shall be applied in the reduction of the price of electricity and the remaining half shall be taken by the company.

Provision should also in the opinion of your committee be made for the following matters:

That the company taking the order shall not transfer to any other company without the consent of the Council.

That the expenses incurred by the Council in negotiations and in the transfer of this order be paid by the Brush Company, this being part of the terms arranged.

That the cost of obtaining the provisional order, not exceeding £350, shall be paid by the Brush Company on completion of the transfer of the order.

That the local authority or the undertakers may apply to the Board of Trade every seven years for revision of the maximum price.

That the usual provisions for security and execution of works—the keeping and audit of accounts – and other necessary powers and provisions for the protection of the local authority, and which are usually inserted in provisional orders granted to companies, be embodied in any document transferring the order.

That no promotion-money shall be paid by the Canterbury Company.

That the order shall lapse to the Council if the company taking the order fails to carry out its obligations.

Alderman Cross, in moving the adoption of the report, said they would see that the sub-committee had gone very fully into the matter of electric lighting. They had had the provisional order before them and had gone through it in detail, and also the agreement drawn up by the Brush Company. The whole of their proceedings had been embodied in the report, and he would, therefore, without any further remarks, move its adoption, and that a copy of it be sent to the solicitors of the Brush Company.

The report was adopted.

CHESTER.

The following report by Mr. Alderman Gilbert, Mr. Councillor Stevenson, and the city surveyor, after their inspection of various installations, has been presented to the Chester Watch Committee:

Brighton.—Brighton represents the two systems of distribution in operation in the same town—viz.: 1. The high-pressure alternating current, supplied by the Brighton and Hove Electric Light Company. 2. The low-pressure continuous current, supplied by the Corporation of Brighton. His Worship the Mayor received the deputation most courteously, accompanied by Mr. Moon, chairman of the Lighting Committee, and other members of the Town Council, with Mr. Tilstone, the town clerk, Mr. Wright, local manager, and Mr. Nebel, superintendent of works, from whom the following information was obtained: The high-tension electricity is distributed by means of overhead wires from the Brighton and Hove Electric Light Company's central station. The company has existed for upwards of 10 years, and the Town Council are somewhat indebted to them for working up the business which, though steadily increasing, is stated to be at present an unprofitable one. The company unsuccessfully applied for a provisional order, and opposed the one granted to the Town Council. Subsequently there were negotiations to purchase the company's goodwill and plant for £7,000; this was not carried through, as the Town Council would not adopt the Lighting Committee's recommendation. A slight variation in the light was observed for a short period at the hotel at which the deputation stayed, but printed testimonials show that consumers are very well satisfied. The installation was by Messrs. Hammond and Co., electrical engineers and contractors, who have also been engaged on the central stations, etc., at Eastbourne, Hastings, West Brompton, and Madrid. This firm's tender has lately been accepted for the first installation of the light for the Dublin Corporation, under Mr. Harty, the borough surveyor, and Mr. Manville, electrical engineer. The streets of Brighton are lighted by gas only; the gas works belong to a company, the charge for gas being 2s. 9d. per 1,000 cubic feet, and it was observed that the majority of the tradesmen were not supplied with the electric light, and that the larger hotels provide the electrical machinery and appliances for their own lighting purposes; and, notwithstanding that the town of Hove is served by this company, it has advertised its provisional order for sale. The Town Council of Brighton have borrowed £30,000 for a period of 30 years, and are now applying for a supplementary loan of £8,500; the eventual total cost of the installation (including £7,000 for site of station) is estimated at £42,000, and this sum it is calculated will supply 10,000 lamps (the usual average, 5,000, being lighted at one time). This station is now supplying 2,500 lamps with current at 7d. per Board of Trade unit, the number lighted at one time being, say, 1,200, and the largest single installation being 300 lights at the Alhambra. The Corporation cannot ascertain profit or loss, having had only two months' experience; an opinion was expressed that loss must arise

on the present output, but that if the maximum is supplied, profit may be made, as the only increased outlay will be in the direction of wages, fuel, etc. Coal costs at Brighton 22s. per ton, the best Welsh steam coal being preferred. The Mayor and members of the Council consider the low-pressure continuous-current and storage battery system the best for compact areas (1¼ miles greatest distance), and therefore for Chester. They advise keeping the order in the hands of the Corporation, having great faith in the future of the electric light. The electric light cost, calculated lamp v. lamp, is double that of gas, but greater illumination is obtained; the consumers' expectation is met by giving a better light, besides improved conditions of health and cleanliness; smaller fire risks, clearer atmosphere, and non-destructive effects are also advantages which are claimed for the electric light v. gas. A very successful installation was examined at the shop of Mr. Cowell, North-street, and that gentleman expressed himself highly delighted with the result, and from enquiry at the hotel the cost of five lamps supplied with current by the Brighton and Hove Electric Light Company for three and a quarter hours is 7d. The Corporation do not put in the fittings on the consumers' premises. It was noted from the experience at Brighton that sub-contracting would not give the best station results; that limited space is undesirable; that the testing-room should be away from the works; that duplicate steam-pipes would be advantageous; and that the appliances, such as switches, etc., should not be placed in immediate proximity to the engines. The area of supply equals one mile square, and up to the present time about 20 miles of cables have been laid in small subways under the footways, etc., of the streets. The land on which the central station is erected is about half an acre in extent, and the plant consists of: Three Lancashire boilers, 28ft. by 7½ft., one as a stand-by, with space for three additional; three compound direct-coupled engines, each developing 98 i.h.p. at 450 revolutions, and supplied by Messrs. Willans and Robinson; dynamos, apparatus, electric instruments, and appliances were supplied by Messrs. Siemens Bros, Goolden and Co., and others; two sets E.P.S. batteries, first cost £2,700, estimated life four to five years; several descriptions of meters in use, ranging from 25 to 100 lights, highest price £10, prime cost; the Aron £5, or on hire 10s. per year. One lamp will hardly register in certain meters. The Edison is considered very accurate. The Corporation keep in repair and regulate all meters. The working hours at the station are from 2 p.m. to 10 p.m., when steam is shut off, the batteries supplying current for the remaining 16 hours. Sixty-six lights were being supplied at the time of visit—11 a.m. The electrical engineer employed at Brighton, as also at Bradford, Portsmouth, and St. James's, Pall-mall, was Mr. Shoolbred; the principal contractors were Messrs. Sharp and Kent.

St. Pancras.—The Vestry of St. Pancras (pioneer in London of municipal enterprise in relation to electricity) commenced their supply on the 9th November, 1891. The installation is of a first-class type, and the latest example of the low-pressure continuous-current and storage battery system, as applied to street and house lighting, and for motive power. Mr. Pyecraft, the vestry clerk's representative, and Mr. Baron, the official in charge, were present at the inspection, and they considered that the low-pressure system would economically serve areas with distances extending three-quarters to one mile, and with sub-stations at 1¼ miles, the extreme distance in the lighting area of St. Pancras being 5½ miles from the central station. The capital expenditure is made up as follows—viz.:

The site	£10,000
Buildings and plant, including five miles of mains	50,946
Royalty for use of three-wire mains	909
Commission	1,988
Sub-station	550
Weighing machine	100
Public lighting (90 lamps)	900
Meters	1,000
Opening expenses	50
Contingencies	3,557
Total	£70,000

This sum is to cover an installation of 10,000 16-c.p. lamps or their equivalent. The charge per Board of Trade unit is 6d., and contracts for supplies equal to 6,000 lamps have been sealed by the Vestry. The lamps for street lighting are supplied direct, and are of excellent design and fixed on the central line of the carriageways at average distances of 50 yards. The current is supplied by two dynamos for this direct lighting. The steam is shut off at certain hours for the house lighting, and if current is then required, it is served by storage batteries and the three-wire system of main distribution. The cables are laid in brick and concrete subways under the footways and carriageways, and dry air is driven through the subways from the central station to expel moisture, etc. The chimney stack is 170ft. high, and the exterior is utilised to assist the condensation of steam, by means of large exposed surfaces of corrugated iron plates affixed thereto. Coal is supplied to the station at 21s. per ton. Six Babcock and Wilcox boilers, working up to 240lb. pressure; 11 Willans and Robinson's triple expansion engines, 170 h.p., with a system in application for condensing; Kapp's dynamos; Brockie-Pell arc lamps for street lighting; Electric Construction Company's No. 55 battery, having transparent glass containers. The loss on storage equals 15 per cent. Measurement of electricity by meters. Charge 2s. 6d. per quarter (smallest size). Prime cost of Ferranti's meter, £6. Frager's meter working similar to clockwork. Prof. Henry Robinson was the electrical engineer employed by the Vestry.

Eastbourne.—The Eastbourne Electric Light Company is stated to be the pioneer company of electric lighting. Capital £28,000. Debentures pay 6 per cent. The old central station has been removed, and changes have been and are being made in the machinery, and this is now fixed in an old building formerly used as a brewery. The Corporation opposed the company's provisional order up to the last moment; and the Board of Trade imposed underground wires, which are carried under public streets in cast-iron pipes; 12 miles of mains are laid. The majority of the shops take the supply; the furthest point of supply being 2½ miles distant from the station. The high-pressure alternating current of 1,800 volts at the central station is transformed by converters to 100 volts on the consumer's premises. The Brush electrical machinery, driven direct from a special engine, is used for the Parade lighting, starting one hour before sunset, and closing down at 11.30. This public lighting consists of 16 Brush arc lamps, 1,000 c.p. to 2,000 c.p., each of which costs 3¼d. per hour, or a total for the 16 lamps of £480 per year. The number of incandescent 16-c.p. lamps is given as 2,000 to 3,000, and a total of, say, 6,000 could be supplied with the present plant, price 10d. per unit—coal 26s. per ton. The day's run commences two hours before sunset, and ceases at 1 a.m., an ordinary semi-portable engine working the remainder of the 24 hours. The plant, as altered, includes Fowler's tubular boilers, 140lb. pressure; Fowler's 150-h.p. compound engines, driving dynamos by belting, and working up to 200lb. steam pressure; Elwell and Parker's dynamos, running at 400 revolutions per minute; Westinghouse meters hired at 5s. per quarter; prime cost ranges from £3. 10s. to £5. The engineers and contractors employed were Messrs. Hammond and Co.

West Brompton.—The West Brompton House-to-House Electric Company was formed in 1889, and the provisional order was unopposed by the Vestry. Capital of company, £70,000. Last week's net profit said to be £180. The installation was the best example which came under the notice of the sub-committee of the high-tension alternating current system with transformers to low tension conveniently placed at or near the premises and small areas supplied with electricity. Mr. Gay, manager, lucidly explained the arrangements, aided by a plan of the district showing all the wires laid permanently or temporarily, with buttons indicating the number of lights for each consumer. The central station is designed for extension up to 12 engines and dynamos to supply 40,000 lamps; at present there are 19,000 lamps installed, the number lighted at one time being about 8,000. The charge made is 8d. per unit; coal 22s. per ton. The representatives of the company are strong advocates of the method of distribution by means of high-tension electricity, the great advantage claimed being the easy method of supply to one or more consumers at considerable distances from the central station; it is said there will be little difficulty in transference to low tension when the area of supply becomes more compact. It is stated that the first heavy cost of machines and mains to supply a few consumers at long distances on the high-tension system is fully counterbalanced by the cost of the four required sub-stations to the square mile, and the battery storage loss rising up to 30 per cent. under the low-tension system. There are 20 miles of mains laid in cast-iron pipes the largest diameter of pipe being 6in. The plant consists of four Babcock and Wilcox boilers, 120lb. to 145lb. pressure; four Fowler's compound horizontal (non-condensing) engines, one only working after 12 p.m.; Lowrie-Hall type of dynamos, driven by ropes from grooved flywheels of engines; Westinghouse meters, small size hired at 5s. per quarter. Messrs. Hammond and Co. were the electrical engineers and contractors to this company.

It will be observed that the coal cost at Chester is but one half the price paid in the towns visited, and this fact, coupled with information derived from various returns, documents, pamphlets, and estimates, demonstrates that Chester is well circumstanced and favourably situated for an installation of the electric light, and as "time" is an important element as regards the lapsing of the Town Council powers under the provisional order, the members of the deputation advise—

1. The introduction of electric lighting for part of the area within the city boundary.

2. That the central station be so designed as to be capable of development with the smallest possible rebuilding, or alteration of machinery.

3. That not more than £15,000 to £20,000 be expended in providing a first installation.

(*Signed*) LEONARD GILBERT, ANTHONY STEVENSON.

COMPANIES' MEETINGS.

CITY AND SOUTH LONDON RAILWAY COMPANY.

The fifteenth ordinary general meeting of this Company was held at Winchester House, E.C., on Tuesday morning, the chairman, Mr. Charles Grey Mott, presiding.

The **Secretary**, Mr. W. F. Knight, having read the notice convening the meeting,

The **Chairman** said: Before proceeding to move the adoption of the report, I am sure I shall be expressing your feelings as well as my own in saying how much sorrow and sympathy we have felt with the Prince and Princess of Wales in the loss of their son the Duke of Clarence. His loss has been a sorrow to the whole country, and the whole country has sympathised with it. But to us it comes home especially, for it is now little more than a year

ago since he was present at the opening ceremony of this railway. He came there at his own request. He took a strong interest in the line, and showed that he fully appreciated the great benefits that a line like this might bring to this country as well as to others. I am sure that we all feel and will desire to express our deepest sympathy with the Royal Family in their sad bereavement.

It now becomes my duty to move that the report and accounts now presented be received and adopted. I regret that we have to meet you again without the declaration of a dividend on the ordinary stock. During the first half of the present year we had, in company with many other lines, an unsatisfactory traffic. Our line is especially affected during the holiday season by the absence of our regular travellers, but we expected that this would be far more than made up by the increased traffic which we should receive owing to the cricket matches at the Oval. Unfortunately, the weather was so extremely bad, as you know, during the whole of that period that there was hardly a match that was in any respect a success, and we got little or no additional traffic from that source. The result was that our average receipts for the first quarter of the half-year were only £704 a week. After the holiday season was over, and people began to get more confidence in our line, our traffic began steadily to increase; so much so that in the second quarter of the half-year our average receipts were raised to £802 per week. We have tried to improve. We thought that part of the want of increase in traffic in the first half might be due to our fares being in excess at some periods of the day, and that a reduction of these fares might produce an increased income. We did reduce and vary them, and on the whole we think that so far the reduction has been successful. But in some cases we have since found that we can increase them again without losing the traffic, and we are taking every opportunity we can of carrying out that policy. The reduction of the fares is evidenced in the following way: The average fare for a passenger in the first half of last year was 1·9d. In the second half it was reduced to 1·7d., inclusive of season-tickets. The reduction of that decimal between ·7 and ·9 amounts to more than £2,000 in the half-year, but it has been more than made up by the increased number of passengers we have carried, and so on the whole of the half-year we show a total increase in receipts of some £600. When we began to raise the fares, as we did on the 1st November last, we introduced a system of season-tickets which has been largely availed of, and the number is steadily increasing, and I am glad to say that those which have just expired are nearly all being renewed, showing that the season-tickets have met a demand, and that we are giving satisfaction to their holders. The great fault of the line is the want of traffic and of sufficient receipts. Our receipts per train mile are 2s. 1½d. Now the average receipts of some of the railways in England are about 5s. per train mile, and on passenger lines they usually somewhat exceed that figure. Our expenses per train mile have been only 1s. 7¾d. The expenses of an ordinary steam railway are 2s. 9d. So that, you see, our expenses per train mile are very much lower than in the case of steam trains. But, of course, our trains don't carry as large a number of passengers as those on an ordinary steam railway. I will come to that point directly. Our total expenses appear to be very high—they always are high in the early stages of a new railway—they amount to 76 per cent. of the receipts for the half-year. But when you compare them with those of an ordinary railway you must recollect that we have, in addition to the traffic of a steam railway, the lifts which take the passengers up and down, which are, of course, quite extraneous to ordinary railway working on the surface. If you deduct the cost of working these lifts, you will find that our expenses for the past half-year are reduced to 66½ per cent. of our earnings, which is a fair comparison with a steam railway. If our receipts had also increased at so fair a rate that instead of having a little over £20,000 we had had £30,000, we could have carried that traffic at little or no practical increase in expenses, and our working expenses would have been reduced from 66½ per cent. to 45 per cent., which is lower, as you know, than almost any steam railway in the kingdom. In the early stages of a railway, as I said, the percentage of expenses is always higher than is the case afterwards, as the traffic develops. I will give you one or two instances which will show you this. The Brighton Company's expenses in 1867 were 85 per cent. of their receipts. Their expenses last half-year were 48¾ per cent. of their receipts. So that you see the growth of traffic brings down that percentage very largely. About the same time the London, Chatham, and Dover's percentage was 71. Therefore, as far as our position compares with theirs in point of age, we are very much in advance of what they were at that time, because we are only a year old, but at the time I have quoted these railways were many years old. Our expenses this half-year have shown certain decreases, which have unfortunately been counterbalanced by certain increases on the other side. Some of these are such items as increase in compensations, one or two claims brought against the Company which we thought it better to settle. They were not very just claims, but they were small things, and have cost us £92. Rates and taxes increased to the extent of £152 over last half-year. Locomotive expenses have decreased by £383, and traffic expenses have decreased by £38. Maintenance of line has increased, because we have the whole maintenance upon us this half-year, whereas we had not in the last half-year. There is a small increase in general charges. The result of this is that the expenses as compared with the previous half-year show a trifling decrease. I am sure it will be very interesting to you, after we have had a year's experience of working by electricity, that I should give some facts and comparisons in regard to it, which we were not able to give before. Of course we cannot say for a moment that the present condition of our working is by any means perfect. We are improving it every day, and I hope we are going to lessen its cost. I will give you a few of the results which we have learned so far during our experience of the last 12 months. Look, first, at our locomotive expenses, which are, after all, the key to the question of electricity *versus* steam. These expenses are 7·88d. per train mile. Now, the locomotive expenses of the main lines of the country, such as the North-Western, Great Western, Midland, and Great Northern, will be something over 9d. per train mile over the past half-year, against our 7·88d. But that is not all. Our charge of 7·88d. includes a price for coal which covers all the carriage from collieries and carriage to our depôt. In the accounts of the other companies the coal is charged as at the pit's mouth, and there is no cartage put on it at all. If you deduct from our accounts for coal the amount which we should have paid for it if we had been in the position of the other companies, you will find that our cost per train mile is reduced to 6·6d. against their charge of 9d. The expenses per train mile of the large companies which pay carriage on coal, such as the Brighton, are not 9d., but over 10d. In reference to the relative economy of electricity and steam, it will be interesting to consider what are the advantages which we can claim for electricity. We have told you in our report that "after the experience of the past year, there is every reason to be satisfied with the use of electricity as a motive power for the working of this railway, and for a confident belief that when all the details are fully perfected it will be found to be at once safe, convenient, and economical." Its safety we have proved, because we have had no accidents. Its convenience is, I think, proved, and will be far more so in the future than in the past. Its economy is what I am now coming to. I have told you that our expenses were 1s. 7¾d., against the usual steam railway figure of 2s. 9d. per train mile. Their (the steam railways) reply to that is, of course, "Your trains are very much smaller and lighter." Well, that is perfectly true. But you must recollect this, that the average number of people that we take in a train—in fact, have taken in the last half-year—is 47. We are really capable of taking three times that amount. The ordinary steam trains all over the country carry 45 passengers per train mile, and the rest of what they carry is deadweight, that is not paying them. I hold that, instead of running huge trains only partially filled, it is better to run smaller and lighter trains which hold a vastly larger proportion of passengers to their weight; and that you had better increase the number of these light trains than have fewer ones of very much heavier weight. It is more conducive to the public convenience, and in the end will, I think, be found more economical. One of the results of our working is this: In an ordinary steam train it is generally reckoned that a ton weight of carriages will provide for three passengers. Of course I am not speaking of trains like the Pullman, but of ordinary ones. In our trains for every ton of weight we can accommodate five persons, so you will see that in our electrical arrangements we have a decided advantage in point of weight over a steam railway. I was very much surprised on reading a report of the Metropolitan Railway meeting the other day to see it stated that that very able and experienced railway chairman, Sir Edward Watkin—whom we look upon as an especial expert in railway matters, and whose opinion is always valuable—had told his shareholders that he had considered the question of electricity, but that he understood that an electrical engine could only draw a train equal to its own weight. Now let us see how far that is correct. An ordinary steam-passenger locomotive such as run on our main lines will take, it is usually reckoned, three times its own weight behind it. That is to say—I am speaking of passenger trains—that if you have an engine 80 tons in weight, it will take 240 tons behind it. Our electric engines are at the present moment always taking more than three times, and even four times their own weight. And you must recollect that in running over our line we are taking that weight up an incline, the ruling gradient of which is 1 in 27, with a reverse curve of about two chains in radius. Now Sir Edward has not got a steam engine which will take an incline like that. We are therefore surpassing with electricity the powers of steam relatively to the work done. These are important facts to have learned in our last twelve months. Our average speed of working at the present moment is 13 miles an hour, including stoppages. We ought to work, and we reckon to work, rather faster than that, and we hope to do so one of these days, but you will recollect that that is considerably above the average speed of Metropolitan Inner Circle trains. They don't attain a speed of 13 miles an hour including stoppages. I think I have shown you in figures that although electricity is only in its infancy as regards this line, which is the first of its kind, and has only been in operation a year, and there has been no time or opportunity to really perfect it, though we improve it from day to day, I think you will see that electric power in the future is not a matter that the engineers can afford to despise. I confess that, having had a very long experience of the management of steam railways in this country and elsewhere, I cannot help feeling that the facts that we have learnt in the past year point to the substitution very largely, and at no very distant date, of electricity for steam over the railways of the world. It is always well when you have got to a certain point to look back and see what your expectations were. If you will look back to our original prospectus—it only referred to the line to The Elephant and Castle—you will find that we estimated for a very high traffic. I believe, if you will follow our advice and allow us to carry out the plans that we have in view, that the time is not very distant when these traffic expectations may be realised, large as they were. If you look also at the expenditure, you will find that in our first estimate—and you recollect that that was an estimate based upon what was supposed to be an extremely economical mode of working,

viz., the cable system—the amount of our expenses proportionately per mile rather exceeds the amount at which we are now working. After I had gone into that estimate very carefully, I considered it very doubtful if it could be adhered to, that it was too low, and in the second prospectus we raised it considerably. I don't think, from what I know, that it would be possible to work this line by a cable system, even if we desired to do so. The cable is an excellent system for certain purposes, and it is extremely good where there are a number of hills, because there you get the effect of gravitation one way helping to ascend the other. On the other hand, to work a railway such as this with the enormous traffics we should have, and are likely to have, by the cable, would involve an enormous strain on that cable, and would require a very strong and heavy one—so heavy that its weight would probably be twice the weight of all our locomotives put together. Then the difficulty of working round a curve, and the friction involved in working over pulleys in a line of this kind, would be very great. It appears to me, therefore, that our views as to expenses are fully borne out. It is clear that if you have that very large weight (the cable) to move before you move the train, combined with friction, you cannot have as economical an arrangement as with light electric engines. I think, therefore, you will see that we are justified in what we have stated in the report, and that the future of our electrical working is a very promising one indeed. Most of our line—nine-tenths of it—is a good one and well constructed; one-tenth, I am sorry to say, has been an engineering blunder—that is to say, King William-street Station and the inclines leading to it. The station is too short, the inclines are too severe, and the curves are very heavy indeed as you come into it. We want, if we can, to add another carriage to our train. We can't do it because of King William-street Station. The inclines also up to that station are at the present moment involving us in a vast expense for additional power, that would be quite unnecessary if we could get rid of them, and if we could do this we could work the line very much cheaper. The station cannot be enlarged, because there is the Monument in front of us, and we are not allowed to approach nearer to that structure, while on each side we have very large buildings, the ground on which they stand being mostly made ground, having been raised at the time that London Bridge was built. Therefore we have only to consider if we cannot in some way get rid of the station and inclines, which constitute only a very small portion of our line, a few hundred yards, and fortunately not a very expensive portion, while it would always be extremely useful even if we substituted other lines for it at a future date. In order to improve and get our line into such a condition that we can work it economically and meet the growing traffic, we think there is no means other than by making a through station in the City instead of having a terminable one. All the steam railways that come into the City, with the exception of the Metropolitan, have terminal stations, and much they regret that this is so. Everyone of the terminal stations are taxed to their utmost with a constantly increasing traffic, and have a problem to solve which it will take the very wisest heads to deal with in the future. With a terminal station it takes from four to five times as long to deal with a train as it would if it was a through station. So you have to have large siding accommodation, which is always getting choked, and yet it is almost impossible to extend it. You know the enormous expenditure the Great Eastern are going to in widening Liverpool-street Station, and yet it will only be a few years before the block will come upon them again. With all this knowledge before us we feel that before we have gone to the expense of making an extensive terminal station, it is wiser at once to take the line through the City, and make our terminal station where we can acquire land at very small cost. If we can have through services you will at once see the enormous difference they will make. We can deal at once with the growing traffic; we can accommodate the excess traffic in the morning and evening, and at very much less cost per train mile than we are doing now. We have power far in excess of our immediate wants—if only we could utilise it we could work a much longer length of line than we are able to do now. All this points to the wisdom and desirability of carrying out the plans which we have now deposited in Parliament (Islington Extension Bill). We have looked about us to see in what way we can make these plans work as economically as possible. We have arranged with the Brighton Company for a station at the bottom of Denman-street, and they will be able to throw upon us at once a large passenger traffic. The moment that station is opened it would be utilised to a very large extent quite apart from the additional facility it would give to our own line, and the traffic that would naturally come from passing through the City, and the traffic promises for that line are exceedingly good in every way. But we felt, in our present financial condition, we might have some difficulty in raising capital to carry out the work; we have therefore taken power for carrying out such portions of it as are necessary by independent capital. Having control of it, however, we can make arrangements by which this Company will have all the benefit without the risk, and I think we see our way to find the capital. This question of independent capital or not, is not to be determined now, but after the Bill has been obtained. It will then rest with the Company whether they carry out the work or not. I would gladly have postponed the application to Parliament if we could. We considered every possible means of coming to you and saying, "It is desirable to postpone it"; and it is only under the strongest feeling that you cannot, with proper regard to the interests of this Company, postpone that application—no! not for a year—that we put it before you. We have considered the matter in every way, and we have come to the absolute positive conclusion, that it is essential to the interests of the Company that that Bill should go on. We ask you as Directors—we have a good deal of knowledge which we cannot quite impart to you, because it would only injure the Company—we ask you for your confidence and to pass the Bill. If there are any here who think that that Bill is not in the interests of the Company, then as far as I am concerned I must bow to your decision, but I say that I am not prepared to carry on the business of the Company if this is your mind. I am so thoroughly and completely convinced that the future success of this line is promptly assured if that Bill goes on, and is certainly risked if it doesn't, that I am prepared to place my position before you on that question. I now beg to move that the report and accounts be received and adopted.

This was seconded by **Mr. Sampson Hanbury.**

Mr. Turnbull asked as to the hitches that had occurred on the line from time to time.

Mr. Drake thought their little enterprise ought not to be compared with large railway undertakings. Theirs was a useful and might prove a profitable line, but it was very small, and if they carried out the Clapham extension in accordance with the Bill they had obtained but not utilised, he thought they might hope eventually to attain to a fair remuneration for the money they had expended. Whatever was the outcome of the application to Parliament for the extension to Islington, one thing was very certain—viz., that heavy charges would come upon that Company. Lawyers, philanthropists though they were, did not work for nothing as a rule. The line was esteemed by all to have the three points of safety, speed, and comfort. It was a necessity now for the locality through which it ran. He would submit that having 3d. to spend, they should not try to make it do the work of 2s. 6d. or 3s. He advocated the carrying out of the extension to Clapham, by doing which they would be making certain if slow progress.

Mr. Middleton congratulated the Board on the reduction in running expenses, but would impress on them that there was yet scope for considerable further reduction in his opinion. He hoped they and the officials would devote their energies to this question rather than to that of the extension.

Mr. Van Laun asked whether it was a fact that electricity as a motive power had practically failed on that line. He felt sore at coming year after year to hear the same story that they were not to receive a dividend. They did not want to be too hard on the Directors; still, they were responsible for what the engineers had done, and the engineers had practically misled the Company. He noticed, with a certain amount of bitterness, that they were asked to extend this failure. He represented two companies that held £10,000 in the Company's shares, and they wanted to know why the shares stood at the price they did. His directors were under the impression that this experiment had failed, and although the Directors had succeeded in paying debenture interest by careful management, yet they were in the unfortunate position that if some mistake the engineers had made was not corrected they would never receive a dividend on the ordinary shares.

The **Chairman** said he would reply to Mr. Van Laun first. He could certainly assure that gentleman that, so far from considering electricity a failure, he thought, from what they knew of it, it was the most decided success from the point of view of locomotion, and promised to be in every way a most satisfactory mode of working that line of railway. Of course, they could not be supposed to earn a dividend until they had worked the line, and they had only had one year in which to work it. During that time they had not only paid their debenture interest, but they had carried forward an amount that might have been distributed in a very minute dividend. The Board did not wish this, however, because they believed that when they next met the shareholders it would be to declare a dividend on the ordinary stock. He confessed he did not see any reason to suppose that they would not be in a position to do so, provided everything went on as they arranged. If shareholders thought the Directors were not to be trusted, then, of course, they must not hold the Board responsible for the results of the future. He could only say that their experience was that electricity was in every way a satisfactory power. As to the stoppages on the line. They were under the glare of the light of public opinion, which was directed on them at the present moment as a new undertaking, and people tried to find out every possible fault they could. They did have stoppages, and not unfrequently, generally lasting from five to ten minutes, seldom more than that. Unfortunately, they always occurred during the busy time, and arose from the strain that was put on the motors of the engines in coming up the incline into King William-street. It had been found in the course of time that the mode of winding the original armatures was not perfectly satisfactory, and owing to this short circuits took place. These would have been remedied at once if the Company had had a large surplus stock of locomotives, but they had not, and they could only take them off as they could be spared. This had been going steadily on for some time. They were rewinding the armatures, and had had no breakdowns with those that had been rewound. As the process could only be carried out by degrees, every now and then an old armature would break down. But if they were delayed 10, 20, or 30 minutes on any of the leading railways entering London, they did not at once write to the papers. Whereas, if they were delayed on the City and South London for 10 minutes, such was the confidence of the public in it that they were always expected to be punctual, and so it was thought more of. In course of time, when the armatures were completed, these breakdowns would be of very rare occurrence. The strain of coming up the incline to King William-street was, however, very great (a steam locomotive could not do it), and would always involve a waste of power. They were doing all they could to reduce expenditure, and so far from being unable to make the line pay, there was no doubt they could make it remunerative up to a certain point. He was quite sure that if they did not look forward

and go for that Bill (the Islington Extension), they would be very sorry for it in the future. He had no interest in saying this beyond the interest of the concern. He told them, from his experience and knowledge and from information the Board possessed, that they would be extremely foolish if they did not authorise the Directors to carry out the policy they had most carefully considered. He then put the motion for the adoption of the report, which was carried unanimously.

Mr. C. R. Grenfell proposed the re-election of the retiring director, Mr. C. G. Mott (the chairman) remarking that they must have come to the conclusion, from what they had seen of him, that he was the right man in the right place.

Mr. Edwin Tate seconded, and the motion was carried unanimously.

The **Chairman** briefly returned thanks for his re-election, remarking that the City and South London had hardly been out out of his thoughts for years. He was most thankful that at last he saw daylight, and a future which, if only shareholders would trust the Board, would place it in a far better position than any other railway in this country.

The auditors, Messrs. Turquand, Youngs, and Co., having been re-elected, the **Chairman** moved that the dividend of 5 per cent. on the preference shares be declared, which was duly seconded and carried.

The meeting then resolved itself into a special general meeting to approve or otherwise of the Bill empowering the City and South London Company "to make an underground railway to Islington, and for other purposes," which is being promoted in the present session of Parliament.

The **Solicitor** having read the principal clauses of the Bill,

The **Chairman**, in moving that the Bill be approved, said he had already dealt with it, but he would like to explain more exactly the necessity for it. He had touched on the objections to that part of their line running under the Thames and into King William-street Station. They had already got power to make a station at the end of Denman-street, which led from the Borough to the London Bridge Station of the Brighton Company. They were unable to carry out this work, however, because they found that the Brighton traffic was very large, and came in in immense quantities just at the time when they were busiest on their own line, so that if they had made the station they could not carry the traffic, because they could not work sufficient trains into King William-street Station. It would require a very large and rapid train service in addition to that which they had now. There was a great outcry amongst both South-Eastern and Brighton travellers because they had no means of getting into the City, except by walking over London Bridge, and he (the Chairman) did not see that there was any other mode than by such a line as he had proposed. Other companies were in the same condition. The South-Western had deposited a Bill for making an electric railway from Waterloo Station to the Mansion House, and the Great Northern had deposited a Bill for making a similar line from their junction at Finsbury to Finsbury-circus. All of them thought that these railways were the best and only means of getting into the City. The Brighton Company had agreed that they (the City and South London) should construct a subway from their proposed station to the former company's platforms, and passengers would walk down to Denman-street Station and thence get into the City. In order to get rid of the present incline, and have a fairly good one into the City, they proposed to go back further than Denman-street, and join on to their present line, and to make two new tunnels from that point past Denman-street under the river, coming out at the upper part of King William-street, near Lombard-street. The line would then be continued under the Central London Railway, with whose Mansion House Station it would have communication, and thence up Fenchurch-street and along Moorgate-street to the Metropolitan Station, with which it was proposed to connect, and also with the Finsbury Station of the Great Northern Railway. The line would then be continued by the City-road, with two intermediate stations, until it got close to The Angel at Islington. Here there was plenty of space and cheap land, and here they could deal with a rapid morning and evening service at a moderate cost. The line should collect an enormous mid-day traffic, which was one thing they wanted to make large dividends. The cost of carrying out the proposed line would be very moderate per mile, not as much, he thought, as the present line had cost. The only special expenses would be for stations, and in connection with the most expensive of these they had promises by which they would be able to largely recoup the expenditure. The line had been very carefully laid out with a view to the greatest possible economy in construction. The Chairman then reiterated his former remarks as to the impossibility of postponing the Bill, and explained the reasons for not doing so. It was a matter on which they must have confidence in the Board. Had they, he said, with some feeling, deserved a want of confidence, had they done anything that shareholders ought not to have confidence in them? On the contrary, he thought the time was come when the shareholders would acknowledge that the labours of the Board had not been in vain.

Mr. Hanbury seconded the motion.

Mr. Middleton, before going into the merits of the case, wished to entirely disabuse the mind of the Chairman and his colleagues as to any opposition on this point having anything to do with a matter of personal confidence in the Board. He thought the way n which the Chairman was re-elected should show that. As to the proposed Bill, he entirely and absolutely—speaking on behalf of £270,000 worth of stock—disapproved of this extension to *Islington* for many reasons. He—and his co-shareholders—thought the short line, the City and South London, should have a fair trial' that everything should be done that could be done to prove whethe or not it could be worked at a profit. The time seemed somewha distant when they were to have any ordinary dividend The Chairman himself had said that the line was a good one, and a good and improving property, and he would counsel shareholders to remain with that and work upon the lines of improving rather than extending it until they saw where they were. He was afraid there was a feeling abroad that they were a railway only, and wanted to get further afield. The original idea of that line was one to get the people of South London into the City; let them carry that out and improve the working before expending their capital of £800,000, and adding to it a capital of one million odd. He would beg to propose an amendment, that in the opinion of that meeting the Bill be not proceeded with for the present. The time might come when they might find it advantageous for them to go to Islington. If they could get a three minutes' service on the line it would add 25 per cent. to their receipts without adding anything hardly to their costs. He thought they should delay extensions until they were justified in carrying them out. There was the Clapham extension which had not been gone on with, why was that?

The **Chairman** pointed out that there was no object in moving an amendment, because that was a direct negative. It would be enough to vote against the motion.

Mr. Mocatta said that it had been stated that if the Bill were gone on with, it could be carried out by an independent company. It had also been stated that the great advantages to be derived in the future would not come to them unless the matter was taken in hand at once. Was it not advisable to take the step recommended while not committing themselves to anything, because others would carry out the Bill?

The **Chairman** was very sorry Mr. Middleton should take the view he did upon the subject. He could not help thinking that the wiser course was represented in what Mr. Mocatta had said. They were not going to propose to carry out the extension without the further assent of the shareholders. It was merely a question whether they would get the power. They could decide afterwards as to carrying it out. The Board thought the arrangements should be in the hands of that Company rather than that an independent party should come in and the Company have to make terms with them afterwards instead of they with the Company. Mr. Middleton asked why the Clapham extension had not been carried out. He thought it was all the more creditable to the Board that it had not been carried out, because they did not quite see until more perfect arrangements were made that the Clapham extension was going to add materially to the line. Having once again made a strong appeal to the shareholders to have confidence in the Board, he put the motion; the figures for which were announced as 26 in favour, and 5 against. The Chairman accordingly declared it carried.

Mr. Middleton demanded a poll, which was fixed for that day week (next Tuesday) at the office of the Company at 12 o'clock, the poll to remain open until 2 o'clock. Mr. James L. Oliver, of Newcastle, was nominated as scrutineer on behalf of Mr. Middleton, and Mr. Donald MacMillan for the Directors.

The proceedings then closed with a vote of thanks to the Chairman.

ANGLO-AMERICAN TELEGRAPH COMPANY.

The half-yearly general meeting of this Company was held on Friday last at Winchester House, Mr. Francis A. Bevan presiding in the absence, through illness, of the Marquis of Tweeddale (the chairman of the Company).

The **Chairman** said he could quite understand that on reading the report there might have been a certain amount of disappointment at the result of the year's working. There had been scarcely any increase in the receipts, for he might explain that of the increase of £6,000 odd, about £4,000 was really a matter of account. There had been an increase in their expenses, but they had had to open new stations in order to meet the very powerful competition which they had to contend against, and they had had to spend rather more than usual upon cable repairs. He was glad to say that the new year had opened better. From the 1st to the 28th inst. there had been daily increases of £50 in their receipts, and if business became better there was no doubt that they would share in the good results that would ensue. A shareholder had suggested that they should increase the dividend by taking something from the renewal fund. It appeared, however, to the Directors that this would not be a wise proceeding. The renewal fund was the backbone of their Company. At the present time their Brest-St. Pierre cable was broken in deep water, something over 1,000 fathoms, and they were endeavouring to repair it. They could not say how much the repair would cost; they could not say even whether they could repair it, though probably they could. It would be most unwise, therefore, to whittle away, as he might call it, their renewal fund. They heard sometimes that they compared very unfavourably with their rival, the Commercial Company, but they had to pay on a very large capital as compared with their rivals, and therefore the comparison after all was not so unfavourable, taking also into account the further fact that the Commercial Company had two new cables, which did not require the repairs that old cables did, and that they had an enormous pull in their connections in America.

The motion was seconded by **Sir James Anderson** and carried after a discussion.

CENTRAL LONDON RAILWAY COMPANY.

The first ordinary general meeting of this Company was held at the offices, 30, St. Swithin's-lane, E.C, on Wednesday afternoon, the Chairman, Mr. F. A. Lucas, presiding.

The **Secretary**, Mr. Matesdorf, having read the notice convening the meeting,

The **Chairman** said he was not going to make a speech, as this was merely a formal meeting held in pursuance of the Act of Parliament. No shares had yet been issued to the public, and so that was practically a meeting of corporators. The only business was to re-elect the retiring directors, and he proposed that the following gentlemen be re-elected—viz., Messrs. De Crano, F. A. Lucas, H. Mosenthal and D. Parish.

This having been seconded, was carried unanimously.

The meeting then became special to consider and approve of the Bill promoted by the Company, which has been deposited in the House of Commons.

The **Chairman** called upon the solicitor, Mr. Morris, to explain the objects of the Bill. In doing this the **Solicitor** said that by the Act of 1891 the Central London Company, which was incorporated by that Act, was authorised to make a railway six miles in length from Shepherd's Bush to Cornhill. By the Bill then before the meeting it was proposed to abandon so much of the authorised railway as was in Cornhill, and instead of having a terminal station there, to continue the line up Threadneedle-street and Broad-street to the Liverpool Station of the Great Eastern Railway, with which, as well as with the station of the North London Railway at Broad-street, it would be connected by subways.

The **Chairman** moved the approval of the Bill, which was seconded by **Mr. Mosenthal**, and carried unanimously.

BUSINESS NOTES.

West India and Panama Telegraph Company.—The receipts for the half-month ended January 31 were £2,735, against £3,791.

Direct Spanish Telegraph Company.—The receipts for last month were £2,195, against £2,147 for January, 1891, showing an increase of £48.

Eastern Telegraph Company.—The receipts for January were £63 436, against £60,005 for the same period of 1891, showing an increase of £3,431.

Eastern Extension Telegraph Company.—The receipts for January amounted to £42,805, against £46,575 in the corresponding period, showing a decrease of £3,770.

City and South London Railway.—The receipts for the week ending Jan. 31 were £823, against £703 for the same period of last year, being an increase of £120. The total receipts for January show an increase of £320 over last year. As compared with the week ending Jan. 24th, last week's receipts show an increase of £11.

The Cuba Submarine Telegraph Company, after providing for the dividend on the preference shares, recommend a dividend on the ordinary shares at the rate of 8 per cent. per annum, tax free. The traffic receipts for January were £3 500, as compared with £2,439 in the corresponding period of last year, an increase £1,061.

Edison and Swan Company.—At a meeting of the Directors on 2nd inst., it was resolved that a payment on account of the dividend of the current year be made on the 89,261 shares, £3 paid, of 5s. 3d. per share; on the 5,000 fully-paid shares, allotted to the Edison Company, 8s. 9d. per share; on the 12,139 fully-paid shares, allotted to the Swan United Company, 7s. 8d. per share. The dividend warrants will be issued on the 22nd inst.

St. James's and Pall Mall Company—The poll on the question as to whether Mr. Egerton Clarke should be re-elected a director of this Company, which was taken last Tuesday at the Company's offices, resulted in his favour by a small majority. He therefore returns to the Board. The circumstances which led to his re-election being challenged were fully given in our report of the above Company's meeting, *vide* last week's *Electrical Engineer*.

Companies Registered during January.—The following electrical companies were registered during the past month:

Electric Fittings Hiring and Maintenance Company, Limited, £5 and £1 shares	£200,500
Elmore's American and Canadian Patent Copper Depositing Company, Limited, £2 shares	200,000
Reading Electric Supply Company, Limited, £5 shares	75,000

PROVISIONAL PATENTS, 1892.

JANUARY 18.

969. **An improved brake for electromotors or for machines driven by electromotors.** Henry Robert Low and Benjamin Creigh, 41, Beaconsfield-road, St. Margaret's, Twickenham, Middlesex.

982. **Improvements in or connected with the manufacture or production of chloride of zinc and alkaline sulphates, and of zinc and chlorine by electrolysis of solutions thereof.** Thomas Parker, Alfred Edward Robinson, and Charles Henry Parker, 47, Lincoln's-inn-fields, London.

JANUARY 19.

1038. **A new or improved manufacture of an exciting material for galvanic batteries.** Hugo Koller, 46, Lincoln's-inn-fields, London.

1041. **Improved means of generating electricity for buildings.** Sarah Jane Rolleson, 50, Goldhurst-terrace, South Hampstead, London.

1061. **Improvements in bleaching and disinfecting starch and fecula by electrolysis.** Eugène Hermite, 11, Wellington-street, Strand, London.

1096. **Improvements in electric signalling on trains.** Alexander Shiels, 70, Wellington-street, Glasgow.

JANUARY 20.

1125. **Improvements in or connected with the side and other lights of electric or other launches or vessels.** Kerbey Deveron Bowen, 57, Chancery-lane, London.

1141. **Improvements in dry electrical elements.** Cæsar Vogt, Temple-chambers, London.

1143. **Improvements connected with electric elevators and motors.** American Elevator Company, Incorporated, 55, Chancery-lane, London. (Otis Bros. and Co., United States.) (Complete specification.)

1145. **Improvements in the manufacture of siliceous insulating material for electrical and other purposes.** Henry Alford Walker, 433, Strand, London.

1147. **Improvements in telephones.** Henry Edward Newton, 6, Bream's-buildings, London. (Parnell Rubbidge, New South Wales.) (Complete specification.)

JANUARY 21.

1163. **Improvements in connection with the brushes of electric generators and motors.** James Young and Robert Simpson, 4, Moorfields, London.

1185. **Improvements in stopping and starting pendulum clocks by means of electricity; the same applies to double pendulum movement as used in electricity meters.** William Green, 11, Stormont-road, Lavender-hill, London.

1216. **Improvements in electric cut-outs.** Hugo Korton, 54, Fleet-street, London.

JANUARY 22.

1254. **The automatic electric intermittent illuminating sign or lamp.** Frederick James Jones, 21, Foregate-street, Chester.

1298. **An improved table for telegraph instruments.** Katie Vonbora Miller, 55, Chancery-lane, London.

1308. **Improvements connected with electric targets.** John Forrest Walters, 166, Fleet-street, London.

1313. **Improvements in electric motor cars.** Sidney Howe Short, 18, Buckingham-street, Strand, London. (Complete specification.)

JANUARY 23.

1337. **Improvements in brushholders for dynamo machines.** Joseph Platt Hall, 17, St. Ann's-square, Manchester.

1340. **Improvements in electrical switches and other apparatus for making and breaking contact.** Henry James Shedlock Heather, 2, Chancellor's-road, Hammersmith, London.

1375. **Improvements in indicating apparatus for high-tension circuits.** Bernard Mervyn Drake and John Marshall Gorham, 66, Victoria-street, Westminster, London.

1391. **Improvements relating to the coating of articles with a new metallic alloy by electro-deposition.** The London Metallurgical Company, Limited, and Sherard Osborn Cowper-Coles, 45, Southampton-buildings, London. (Complete specification.)

1396. **An automatic electric circuit breaker.** Anton Eichler, 4, South-street, Finsbury, London. (Complete specification.)

1402. **Improvements in heating by the electric arc, and in apparatus therefor.** Henry Howard, 24, Southampton-buildings, London.

JANUARY 25.

1426. **Improvements in electrical batteries.** Cresacre George Moor, 13, Market-street, Penistone.

1436. **Improvements in friction driving gear for dynamo-electric and other like machinery.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Armand de Bovet, France.)

1459. **Apparatus for adjusting commutators of dynamo-electric machines and motors to varying speed.** William White, James Radcliffe, and Frederick William Cooke, 28, Southampton-buildings, London.

1464. **Improvements in holders or sockets for incandescent electric lamps.** Thomas Jenner, 77, Chancery-lane, London.

JANUARY 26.

1479. **An electrical signalling and braking apparatus specially applicable to railway trains.** Guy Hamilton and Ernest Cockburn Day, 2, Lugar-place, Kelvinside, Glasgow.

1484. **Improvements in and relating to secondary batteries.** Justus Bulkley Entz and William Alfred Phillips, 70, Market-street, Manchester. (Complete specification.)

1497. **Improvements in couplings for electric wires.** Alexander Shiels, 159, Coldharbour-lane, Camberwell, London.

1552. **Improvements in telephone transmitters.** Joseph Goffin, 45, Southampton-buildings, London.

1557. **Improvements in electromagnetic apparatus for producing a reciprocating motion and for supplying intermittent electric currents for that purpose.** Richard Threlfall, 45, Southampton-buildings, London. (Complete specification.)

1571. **An improved incandescent lamp.** Ernest Frenot and Georges Nouville, 46, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1883, Section 103, July 21, 1891, being date of application in France.)

1580. **An improved electric low-water alarm.** Stephen Martin Mathews, 53, Chancery-lane, London. (Complete specification.)

JANUARY 27.

1626. **An improvement or improvements in the holders or carriers of electrical incandescent or glow lamps.** *Richard George* Evered, 7, Staple-inn London.

1637. **Improvements in and connected with telephones.** George Lee Anders and Walther Köttgen, 55, Chancery-lane, London.

1641. **Improvements in electromotors for electrically-propelled vehicles.** Alexander Siemens, 28, Southampton-buildings, London.

1656. **Improvements in electric brakes.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Armand de Bovet, France.)

JANUARY 28.

1666. **Improvements in electrically-operated means for preventing railway collisions.** George Coles, Bristol Bank-buildings, Bristol.

1682. **Improvements in electrical arc lamps.** Oliver Firth, Sunbridge-chambers, Bradford, Yorkshire.

1695. **Improvements in instruments for the measurement of electromotive forces.** Thomas Parker and William Armistead, The Electric Construction Corporation, Limited, Wolverhampton.

1734. **An improvement in electric compasses and course recorders.** Joseph von Peichl, 28, Southampton-buildings, London.

1737. **Improvements in electric clock mechanism.** Alfred Julius Boult, 323, High Holborn, London. (Frank Alexander Ellis, ——.)

JANUARY 29.

1748. **Improvements in dynamo-electric machines.** Eugen Conrady and George William Brown, 56, Low-street, Keighley, Yorkshire.

1752. **Improvements in microphones.** Gustav Binswanger, 71, Queen Victoria-street, London.

1786. **Improvements in or relating to tanning by electricity.** Raffaele Pinna, 323, High Holborn, London.

JANUARY 30.

1829. **A portable electric planing and polishing machine.** Malcolm Sutherland, Leven Shipyard, Dumbarton.

1852. **Improvements in apparatus for registering electric and other currents.** Henry Raison, 27, Martin's-lane, Cannon-street, London.

SPECIFICATIONS PUBLISHED

1891.

2518. **Electro-depositing.** Gibbings. 8d.
3426. **Brushes, etc., for electric machines.** Dowsing. 8d.
3553. **Electric railways.** Thompson. (Reed.) 8d.
3738. **Electrolysing and bleaching.** Marx. 8d.
3893. **Electrical cables.** Glover and Preece. 8d.
3957. **Measuring electricity.** Miller and Woods. 6d.
4120. **Electric incandescent lamps.** Fryer. 8d.
5003. **Incandescence electric lamps.** Johnson. (Mace.) 8d.
12985. **Electric railway signalling.** Annesley and others. 8d.
14386. **Electric motors.** Dymond. (Gutmann). 8d.
14702. **Secondary batteries.** Hauser. 8d.
16870. **Dynamo-electric machines.** Sutcliffe and Atkinson. 6d.
17614. **Electric wire couplings.** Shiels. 6d.
17731. **Electric motors.** Linders. 6d.
17732. **Electric motors.** Linders. 6d.
20604. **Electric motors.** Lake. (Stanley and another.) 8d.
20629. **Incandescent electric lamps.** Dorman and Smith. 6d.
20678. **Electric burglar alarms.** Pohl. 6d.
20840. **Dynamo-electric machines.** Nebel. 8d.
20913 **Electrically-propelled vehicles.** Dewey. 8d.
20924. **Electric fire engines.** Dewey. 8d.
20930. **Electrically-propelled vehicles.** Dewey. 8d.
21442. **Secondary batteries.** Lake. (Roberts.) 4d.
21448. **Incandescent lamps.** Pitt. (Böhm.) 6d.
21449. **Electrical switches.** Howard. 6d.
21565. **Microphone.** Redfern. (Deckert.) 6d.

NOTES.

The Telephone Bill.—Various local boards are joining together to oppose the National Telephone Company's Bill.

Lambeth.—The formal notice of the revocation of the Lambeth electric supply order has been received by the London County Council from the Board of Trade.

Chichester.—The Lighting Committee of Chichester are thinking of establishing a telephone line between the city and the water works pumping station at Fishbourne.

Bury.—At the Bury Town Council meeting last week the report of the General Purposes Committee upon electric lighting was brought forward, but further consideration was adjourned.

Aberdeen.—It is proposed to extend the tramways at Aberdeen for 1½ miles to the suburbs. Aberdeen should be informed of the work of Leeds in running suburban tramways by electricity.

Journalistic.—The two editors of the newly-established American *Electricity*, Mr. Herbert Laws Webb and Mr. George H. Guy, together with Mr. Paine, their business manager, have resigned.

New Zealand.—Messrs. Postlethwaite and Stephenson have purchased the going business of the New Zealand Engineering Company in Dunedin. Special attention is to be given to electrical engineering.

Swansea.—The speculative builder is not going to be behind the times. One contractor at Swansea is fitting up for electric light, inside and out, whole rows of middle-class houses he is building in the suburbs.

Birmingham.—The process of electric welding was explained and exhibited by Mr. A. Driver, engineer to the Small Arms Company, at the company's works, at a meeting of the Birmingham Mechanical Engineers.

Royal Meteorological Society.—A "Note on a Lightning Discharge at Thornbury, Gloucestershire, July 22nd, 1891," will be read by Ernest H. Cook, D.Sc., before the Royal Meteorological Society on Wednesday next.

Fulham.—The Fulham Vestry has affixed its seal to a petition against the application of the Putney and Hammersmith Electric Light and Power Supply Company for a provisional order to supply the district with electricity.

Gibraltar.—It will be remembered that some time ago Mr. W. H. Preece, F.R.S., was commissioned to report upon the lighting of Malta and Gibraltar for the Government. We learn that the lighting of Gibraltar has now been determined upon.

Cheltenham.—The surveyor of Cheltenham, finding that the cost of lighting the town destructor would be £70 for pipes and fittings alone, and that for less than that sum an efficient system of electric light could be provided, has fitted up the installation, which the Council have approved.

Liverpool Telephonic Dinner.—The second annual dinner of the Liverpool branch of the National Telephone Company's employés was held on Saturday, when 70 persons sat down to dinner, music, and speeches. The transmission of the remarks and music in this case was by ordinary old-fashioned sound vibrations.

Church Telephones in Glasgow.—The proposal of the National Telephone Company to establish a telephone service with St. George's Church, Glasgow, was referred to the Kirk Session for remarks, some members of the council observing it would be a distinct encouragement to non-attendance, and might influence the seat-letting.

Personal.—Mr. W. J. Hammer, the well-known electrical expert, who organised the Edison exhibit at the Paris Exhibition, is now in London, and is staying at the Hotel Savoy. For the past two years he has been carrying on a consulting practice, and is now visiting Europe in the interest of some of his clients in electrical matters.

Society of Arts.—The last of Prof. Forbes's lectures on "Electrical Distribution" will be given before the Society of Arts next Monday, dealing with generators of electricity by water power and by steam from destructors; account of destructors; hydraulic accumulator; utilisation of local circumstances; probable developments in the future.

Bermondsey. — At last week's meeting of the Bermondsey Vestry the General Purposes Committee reported that the surveyor had seen the engineer of the London Electric Supply Company, and found there was no difficulty in lighting the streets by electricity. The surveyor would bring up an estimate of the cost at the next meeting.

Blackburn.—The Blackburn Corporation are taking up the electric lighting question vigorously, and have commissioned Mr. Thomas Burton, electrical engineer, to map out a large central area for illumination with the electric light. The Corporation's parliamentary powers expire in August next, and it is intended to have at least 2,000 lights going before then.

Train Lighting.—An experimental train, consisting of new American buffet and drawing-room cars, was run on Tuesday over the South-Eastern line to Dover. The cars, which are very commodious, are luxuriously fitted and have all the latest improvements, including the electric light. It is understood that they will be run in connection with the continental service.

London School Board.—A recent meeting of the London School Board adopted a recommendation of their Works Committee to spend £3,600, exclusive of fittings, for an electric light installation for their enlarged offices. The committee find that the whole of the offices can be lighted by electricity for £550 a year, whereas even the present gas bill is over £600 a year.

Clerkenwell.—The Clerkenwell Vestry intend to offer no opposition to the application to the Board of Trade by the Brush Electrical Engineering Company, asking for an extension of time for making the deposit under the order of 1891 until one month after the confirmation, refusal, or withdrawal of the order now being applied for by the County of London Electric Lighting Company.

Dufftown.—A display of electric light has been given in Dufftown by Provost Symon in order to show the superiority of the electric light over gas, and so popularise the introduction of electricity into the town. A 2,000-c.p. lamp was supplied by a dynamo driven by a traction engine. At a meeting subsequently held it was almost unanimously resolved to introduce the electric light at once.

Coast Communication.—Amongst the notices of motions before the present Parliament is one for March 4 by Sir Edward Birkbeck to call attention to the loss of life and property on our coasts, and the necessity for improved telegraphic and telephonic communication. All the forces of naval, commercial, and electrical circles should be called up to give force to Sir Edward Birkbeck's motion.

Design of Dynamos.—A meeting of the Association of Birmingham Students of the Institution of Civil Engineers was held on Thursday evening at the Midland Institute, the president, Mr. J. Edward Willcox, A.M.I.C.E., being in the chair. A paper was read by Mr. T. Rooke,

Student Inst.C.E., "On the Design and Construction of Dynamos," which was followed by an interesting discussion.

Inverness.—The proposal to light Inverness by electricity has been abandoned for the present. At a meeting of the Town Council on Monday a motion was definitely adopted discharging the committee appointed to investigate the matter on the ground that the scheme would cost between £30,000 and £40,000. At the same meeting it was resolved to extend the gas works at an estimated cost of £9,800.

Electric Light and Fog.—A correspondent of the *Scotsman* points out, with reference to the wreck of the "Eider," that an electric beam can usually be seen at a far greater distance if sent vertically into the sky instead of horizontally. This was, we believe, found to be the case at the Naval Exhibition, and it would be interesting to have the combined experience of lighthouse engineers and seamen upon this increasingly-important subject.

Godalming.—The Godalming Electric Lighting Committee recommended at the last Town Council meeting that the sum of £25 be paid to Messrs. Day and Co. for charges and fees in connection with the electric lighting. Alderman Gammon (one of the committee) stated that the sum of 10 guineas was for getting up specifications for the town and for plant, and was an entirely separate item. The recommendation was unanimously adopted.

Lynton.—At the Lynton Local Board meeting last week a letter was read from Mr. Green stating that he had assigned all his rights in the electric works at Lynmouth to Mr. Benn. A petition was read, signed by most of the residents at Lynmouth, asking for a 2,000-c.p. arc light to be placed on the Tower for the benefit of the fishermen and the lighting of the Esplanade and lower part of Lynmouth. This was referred to the Lighting Committee.

City Meat Market.—At the meeting of the Commissioners of Sewers on Tuesday the clerk read a letter from the town clerk relative to a petition from Messrs. Julius Sax and Co. to light the central markets with the electric light, the Central Market Committee being anxious to know the position in which the Commissioners stood in regard to the present lighting arrangements. On the motion of Mr. Sayer, this letter was referred to the Streets Committee for consideration.

Gas.—One of our gas contemporaries throws out a challenge to the electrical press to give an opinion upon Colonel Makins's figures in his speech to the Gas Light and Coke Company. What would be the use of such an opinion even in conjunction with any statement of Mr. Preece's? What conclusion does our gas contemporary come to from these figures? Ours is favourable to the electric light, and there is no difficulty in stating why it is so; but first let us hear what gas says.

Torquay.—At the Torquay Town Council meeting last Friday, Mr. Harrison said that seeing they had spent £500 in acquiring powers for lighting the town by electricity, he thought they should proceed with the matter, as the compulsory powers would soon expire. The Board should get the advice of an expert. Dr. Richardson said the license giving compulsory powers would not expire until July, 1893, so that there was a year and a half to run. The Electric Light Committee were giving the matter consideration.

Marseilles.—A strike of a novel character has occurred at Marseilles. The inhabitants have long been complaining of the exorbitant charges of the gas company, and recently a league of the largest consumers has been formed. A notice has been sent in that after the 25th, if a reduction *is not made,* the league will use no more gas, and pending the introduction of the electric light many have laid in stocks of lamps and petroleum, and on Monday many of the establishments on the Cannebière were illuminated by oil lamps.

Electric Tramway for Perth. — At a special meeting of the Perth Police Commission last week, consent was given to the proposed provisional order authorising the construction of an electric tramway between Perth and New Scone on condition that the clauses as agreed to by the Commission be accepted by the promoters. The Commission ask £50 towards the cost, stipulate that operations be not commenced till two-thirds of the capital is subscribed, that the promoters pay £250 towards the cost of widening High-street if necessary, and pave between the rails on Perth Bridge.

London Railway Schemes.—The London County Council have decided to petition against the Baker-street and Waterloo Railway Bill, the Central London Railway Bill, the City and South London Railway Bill, the Great Northern and City Railway Bill, the Hampstead, St. Pancras, and Charing Cross Railway Bill, and the Waterloo and City Railway Blll, with a view to securing the insertion of clauses prohibiting the companies from bringing forward their buildings beyond the general line of frontage of buildings in streets; and also to obtain sewer, bridges, placard, or other necessary clauses.

Strikes.—Messrs. Ernest Scott and Mountain, Limited, Close Works, Newcastle-on-Tyne, are fortunate in being in full work during the present extensive strike on the Tyne, as their men remain at work in all departments. They, however, were the victims of a strike about a year ago of a very similar character to that now going on, and which arose from disputes between two classes of their foundrymen, resulting in the entire loss of employment to all the brassfounders in their works, the work being since then satisfactorily accomplished by men brought from other departments, against whose use in the brass works the brassfounders had struck.

Coloured Glasses.—It is seldom our pleasure to notice such an elaborately printed catalogue as that just issued by Messrs. Paterson and Cooper of electric globes, shades, and reflectors. Broad shades and narrow shades, plain, crinkled, twisted, convoluted, veined, and variously streaked and coloured—some scores of different patterns are beautifully represented in their actual colours; and, if we may believe the figures, there must be some thousands of different varieties. This is evidently a catalogue that no good electrical contractor can afford to be without, either to choose from himself or to charm the heart of the lady of the house he is wishing to light up. The shades can then be selected in perfect harmony with their other surroundings. For London customers, the shades themselves can be seen at the firm's West-end branch in Princes-mansions.

New Bahamas Cable. — Another link between England and one of the colonies has been completed by the successful termination on the 4th inst. of the laying of a cable by W. T. Henley's Telegraph Works Company between the Bahamas and Jupiter Inlet, on the coast of Florida. The Act authorising the construction of the cable was passed last session, and the contract for the manufacture and laying of it was made with the company, whose cable ship "Westmeath" left England at the end of December last. Congratulatory telegrams passed between the company and Sir Ambrose Shea, the governor of the Bahamas, expressing hope of the usefulness of the cable in binding together the colony and the mother country in close bonds of commercial intercourse and affection,

The return message said "Cable worked splendidly—contract most faithfully performed."

Paterson and Cooper—A Disclaimer.—Mr. W. B. Esson writes taking exception to the statement in our biographical note, that the extension of Paterson and Cooper's "work in various directions is due entirely to the energy and ability of the manager." "The success of the firm," he observes, "can be attributed to no particular individual, and it must not be forgotten that the partners themselves work most energetically in their respective departments. To run an electrical business successfully all concerned must work hard, and work together, and in this respect the firm of Paterson and Cooper is no exception." We scarcely think our note likely to be misunderstood, for it is well known that the principals of the firm have been most energetic in developing the several branches of their now extensive business.

British Association.—The meeting of the British Association at Edinburgh this year, under the presidency of Sir Archibald Geikie, is likely to be exceptionally well attended, for not only is the locality very attractive, but a very strong list of presidents of sections has been made. At its last meeting the council of the association was informed that the following had accepted nominations as presidents of sections: Section A, Prof. Schuster, F.R.S.; Section B, Prof. H. McLeod, F.R.S.; Section C, Prof. Lapworth, F.R.S.; Section D, Prof. W. Rutherford, F.R.S.; Section E, Prof. J. Geikie, F.R.S.; Section F, the Hon. Sir C. W. Freemantle, K.C.B.; Section G, Prof. W. C. Unwin, F.R.S.; Section H, Prof. A. Macalister, F.R.S. The Committee upon the Prehistoric Remains of the British Islands is continuing its work, and it is expected to present its report to the committee of Section H at Edinburgh.

Electric Vehicles.—The Parliamentary Committee of the London County Council report that the object of the Ward Electrical Car Company's Bill is to authorise the Ward Electrical Car Company, by agreement with local authorities, to use electrical carriages, and on being licensed, to ply for hire with them. This being the first application for licensing for hire electrical power, with the concurrence of the Highways Committee, they consider that the present opportunity should be taken for making the Council the licensing authority for the user of the cars, and that the licensing should not be left to the Home Office. As the Bill is at present framed, nothing can be done without the consent of the local authority. They recommended at the County Council meeting on Tuesday that the Bill should be amended so as to make the Council the licensing authority for plying for hire, and that a petition be presented against the Ward Electrical Car Company's Bill. This was agreed to.

Southend Pier.—The tramway at the Southend Pier seems to have had a satisfactory result in stimulating passengers to pay for rides, for we find last week at the Southend Local Board Mr. Wood proposing to extend the facilities. The Pier Committee reported that they had under consideration the question of the desirability of providing additional plant and rolling-stock, and recommended an engineer should be appointed to advise. The chairman opposed this report, as he thought with a little alteration the old tramcars might be utilised. He would advise them to first get a perfect system with the present arrangements, and then consider this further increase. Mr. Allen said they must have a duplicate engine, in case of a breakdown. Besides, they wanted more light, as they wanted to light the pier from one end to the other; which, when done, would make the fortunes of the watermen, who could row their fares round it. Mr. Pawley complained of the present cars. The recommendation was carried.

Liverpool.—At a meeting of the Watch Committee of the Liverpool Corporation on Monday, the question of the provisional order applied for by the Liverpool Electric Supply Company, Limited, was again under consideration. A letter was read from the solicitors of the company, Messrs. Ayrton, Radcliffe, and Wright, expressing willingness to negotiate on the terms suggested at the Council meeting for the purchase of the undertaking of a going concern any time after the year 1895, upon giving 12 months' notice to the company of their intention to do so, and on condition that the Corporation extend the ordinary time for the purchase under the terms of the Electric Lighting Act to 40 years instead of 21 years and 42 years respectively, as at present. After discussion it was resolved that the town clerk be authorised to communicate with the company on the subject. It is stated that the committee were willing to proceed with the negotiation to purchase, as a going concern, on the basis of the proposal submitted and at a fair valuation.

Reading.—The Reading Town Council last week had before them the report of the General Purposes Committee. In this report it was stated that the town clerk reminded the committee that the license proposed to be granted to the Laing, Wharton, and Down Construction Company, Limited, to supply electricity for lighting purposes within the borough had remained in abeyance for some time past, the Board of Trade having refused to allow the insertion in the license of a clause providing for the transfer thereof to a prospective company, and that in these circumstances a company had been in process of formation. The town clerk further submitted recent letters on the subject from Mr. H. F. Kite, the solicitor to the Laing, Wharton, and Down Construction Syndicate, Limited. It was resolved to recommend that the Council give consent to a license being granted to the Reading Electric Supply Company, Limited, subject to the form of the license being finally settled to the satisfaction of the town clerk, and being approved by the Council. The Council have decided to light the municipal buildings.

Hampstead and Charing Cross Railway.—The promoters of the proposed Hampstead, St. Pancras, and Charing Cross Railway scheme have deposited the parliamentary estimates for the construction of this railway, prepared by Sir Douglas Fox, C.E., and Mr. J. H. Greathead, C.E. The total cost of constructing this line, with all subsidiary works, is estimated at £1,255,815, of which £1,030,656 is for the main line, four miles four furlongs in length, from Charing Cross to High-street, Hampstead; £185,809 for the short line, six furlongs four chains in length, from under the Hampstead-road to the King's Cross Station of the Great Northern Railway; £7,150 for the subway under the Strand to connect with the Charing Cross Station of the South-Eastern Railway; and £2,200 for a bridge for foot passengers between St. Pancras and King's Cross Stations. The railway, if sanctioned, is proposed to be constructed in two separate tunnels, one for up and one for down traffic, and of the total cost, it is estimated that £729,860 will be expended in the actual tunnelling. The acquisition of land and buildings will, it is estimated, cost £240,000; the construction of stations, £107,100; and for general contingencies a sum of £118,170 is allowed.

Bradford.—The electric light station at Bradford has made a profit of nearly £1,000 during the last half-year. At the meeting of the Bradford Town Council on Tuesday, Alderman Priestman, chairman of the Gas and Electricity Committee, presented a detailed statement for the half-year ending Dec. 31st. He was pleased to be able to say that his anticipations a year since had been amply fulfilled.

For the supply of electricity the balance to net revenue account was £2,001. 14s. 6d. The net profit for the half-year was £971. 4s. 10d. The first half-year's loss was £1,079, the second £733, the third £315, and the fourth £30, being a total of £2,157. Thus, with the profit made during the past half-year, there had been only a loss of £1,186, after having paid interest on sinking fund from the very first day of borrowing money for the electric works. As to the cost of coal in the production of electricity, he said the average was 7s. 7d. per ton, or 1·258d. per Board of Trade unit, which was regarded as equal to from 1½ h.p. to 2 h.p. He believed that, as compared with what was done at other electric lighting stations, the works of the Corporation would be found to be most economical; and he believed that if they had to start again they would not be able to improve upon the system which had been adopted.

Glasgow.—At the meeting of the Glasgow Town Council on the 4th inst., the special committee on electric lighting recommended that the business, heritable property, plant, and machinery belonging to Messrs. Muir, Mavor, Coulson, and Co. should be acquired by the Corporation at the price of £15,000—the Corporation to receive possession on 1st March next. Mr. Mitchell moved the approval of the minutes. Mr. Bell, in seconding the motion, said that Messrs. Muir, Mavor, Coulson, and Co. some time ago offered their works at £30,000. The committee did not entertain the offer, but now, as it had been reduced to £15,000, the committee were unanimous in recommending that it should be accepted. Bailie James Martin wished to know what was included in the £15,000, and pointed out that when the time came for the Corporation to supply electric lighting, they would require to put the wires underground, and the overhead wires would have to be taken down. Mr. Bell said the committee appointed two commissioners to go over the works, and their valuation amounted to £13,000, without taking into account anything for the goodwill of the business. Seeing that they were only asking £15,000, the committee were unanimous in thinking that the business should be acquired. Mr. Alexander Murray asked the amount of the valuation of the overhead wires. Mr. Bell said he did not know that the overhead wires were separately valued, but the valuation would probably be £1,000 or £1,500. The minute was then approved.

Mains in Berkeley-square.—The Highways Committee of the London County Council report that they have considered a notice from the London Electric Supply Corporation of intention to lay distributing mains, consisting of concentric lead-covered cables drawn into cast-iron pipes, in Charles-street, Berkeley-square, and Chesterfield-street. Similar works having been approved by the Council on previous notices of this company, they recommend that the sanction of the Council be given to the works referred to in the notice upon condition that the company give two days' notice to the Council's chief engineer before commencing the works; that the mains be laid under the footways, and be kept 9in. below the under side of the paving wherever it is practicable to do so; that where the mains cross the carriageways they be kept at the same depth below the concrete or the road material, as the case may be; that the positions of the street boxes, and the mode of construction of them, shall be submitted to and approved by the Council's chief engineer; that all pipes or openings from or into the boxes shall be of such shape as to remove all risk of injury to the covering of the cables; that all cables crossing the boxes shall be supported from below in the boxes; that all service lines or small cables shall be protected, where leaving the boxes, by an extra lead covering or by wooden stoppers, and shall also have a copper wire of sufficient size carried from the service to the main cable, in good connection with the lead or iron outer casing; and that the ends of all mains terminating elsewhere than in a box shall be securely protected by iron caps, in addition to any other covering.

Waterloo Electric Railways.—The parliamentary estimates for the construction of the proposed railway from Waterloo to Baker-street have been prepared in accordance with the Standing Orders of the House of Commons. These estimates, which are signed by Messrs. Galbraith and Church, the engineers to the London and South-Western Railway Company, and Mr. J. H. Greathead, the engineer to the City and South London Railway, set down the total cost of constructing this line, including £32,000 for contingencies, at £990,000, or at the rate of just under £330,000 per mile, the total length of the proposed railway being three miles six chains. The cost of the actual tunnelling is estimated at £438,435, including the tunnel under the River Thames near Hungerford Bridge. The erection of the stations will absorb £189,500, whilst laying down the permanent way is estimated to cost £5,000 per mile. The railway for its entire length will be constructed underground. The parliamentary estimates for the construction of the proposed underground railway from near Waterloo Station to Mansion House-street have also been duly deposited by the promoters. These estimates set out the length of the line as one mile four furlongs 6·80 chains, and the total cost of construction at £499,769, or at the rate of about £333,178 per mile. Of this sum it is estimated that £144,300 will be required for the acquisition of land and buildings. The cost of tunnelling is set down at £208,615; of the erection of stations at £66,500; and for general contingencies a sum of £46,365 is allowed. These estimates are signed by the same engineers as the Baker-street and Waterloo railway scheme.

Thermo-Electric Stoves.—There seems to be something fatally "low," if one may so express it, about the vibrations of ordinary heat which prevents them from being used, except at several degrees of transformation, for the generation of electric currents. Notwithstanding Lord Rayleigh's *pronunciamento*, many investigators are hard at work at that most difficult and elusory problem of the present age, the direct generation of electricity from heat. Several recent attempts at advance in this field have come under our notice, and the direction of these seems to be at present more in the desire to utilise waste heat for the production of electricity as a by-product than in any direct attempt to force the heat vibrations to a higher scale on an efficient and economical footing. One of the recent ideas is the employment of the thermo-electric couples in a tubular form, each tube forming itself a Bunsen burner. The idea is clever, and the efficiency considerably higher than forms in which the white light of gas burners is used. A further development has been introduced by Dr. Giraud, of Chantilly, near Paris, who wishes to utilise the heat from an ordinary stove to furnish electric current as well. The products of combustion rise through an inner tube and descend the annular space between this and the walls of the stove. The heated gases are brought into contact with elements of nickelled and tinned iron and a zinc-antimony alloy, contained in stamped iron boxes. The capacity is given at 40 watts, the cost being about 1s. 3d. a unit, considering the total cost of coke. The idea may quite well be worth while being taken up tentatively by stovemakers, in conjunction with electrical engineers, for the utilisation of the waste heat in grates and stoves, and the study of these problems might lead to greater knowledge of the best arrangement for the use of heat on larger scales for the direct generation of electricity.

Town Lighting in Queensland.—We are able to report the immediate establishment of a central station at Rockhampton, Queensland, by the Rockhampton Gas and Coke Company, which has now an active electrical department. In November, 1889, this company procured an amended Act of Parliament from the Queensland Government to supply electricity for all public and private purposes within the municipality of Rockhampton and the borough of North Rockampton, including the bridge over the River Fitzroy that separates the two townships. The company have been carefully watching the growth of the electric supply companies in England, Europe, and Australasia, and a month or two ago issued a circular notifying customers of their intention to erect plant for supply at the rate of 1s. per unit, including meter rent, to see with what success the company would meet with if they put down a central station. This circular met with such success that the company decided to put down at once a plant for the supply of electricity. For this purpose they have since purchased a very central site in the busiest part of the town, and on this they will erect a central station. The method of distribution will be on three systems—viz., for 500 yards in each direction of the central station the system will be low tension (two wire) at 110 volts; beyond this area the system will be alternate-current transformers; and for the public street lighting (negotiations for which have been opened up with the Town Council), the system will be direct-current series arcs. The town is laid out on the block system, as in Melbourne, and the lamp columns for the arcs will be placed on refuges at the intersections of the various streets. A plant for 1,000 16-c.p. lamps for the low-tension, and 500 10-c.p. lamps for the alternate-current system will be put down at once. So far, 850 16-c.p. lamps have been taken up. The supply will begin about July next. The whole of the work has been planned out, and will be carried out under the supervision of Mr. A. E. Neal, the company's electrical engineer. The company will also carry out isolated installations in Queensland. Gas in Rockhampton is from 7s. 6d. to 12s. 6d. per 1,000ft., according to quantity consumed, or for lighting or heating, so that the company will have a good chance of successful competition with itself.

The Lighting of Larne.—A meeting of the residents of Larne was held on Thursday last week for the purpose of considering the question of the electric lighting of the town. The Commissioners adopted electric lighting on August 1 last, and their action has recently been called in question, with a result which has vindicated their progressive policy. Mr. John Fullerton, chairman of the Larne Town Commissioners, presided. Mr. Picken moved: "That the lighting of the public streets of Larne during the past six months has been imperfectly and insufficiently performed, in consequence of which the ratepayers and inhabitants have suffered serious inconvenience; and that the agreement entered into between the Larne Town Commissioners and J. E. H. Gordon and Co., Limited, London, has been effected without due regard to the interests of the ratepayers of Larne, who disapprove of the action of the Commissioners, particularly in attempting to concede to Messrs. Gordon and Co., Limited, the sole right of public and private lighting of the town by electricity for 42 years from 1891. That before entering into such an agreement the ratepayers should have been consulted, and their opinion taken in the matter." Mr. Thomas M'Cormick formally seconded the resolution. Mr. James Boyd moved the adoption of the following amendment, amid loud cheers: "1. That the ratepayers of Larne, in public meeting assembled, hereby express their great satisfaction with the public lighting by electricity of the principal streets of the town. 2. That they express no opinion (at present) in reference to the minor streets and suburbs, seeing that as soon after the new dynamo is in operation as possible, the contractors will replace the temporary lights now in use by more powerful ones, which it is expected will give every satisfaction. 3. That the agreement entered into between the Commissioners and the contractors, Messrs. Gordon and Co., being the usual one prescribed by the Board of Trade, is considered satisfactory, and that the Commissioners deserve the best thanks of the town for their enterprise and public spirit in introducing the electric light, and hereby have our confidence and support." Mr. John Bain seconded the amendment. Those who were not ratepayers were then asked to go upon the platform, and tellers having been appointed the chairman put the amendment, with the following result: For the amendment, 74; against, 48. The proceedings then terminated.

Burnley.—At the monthly meeting of the Burnley Town Council, on the 3rd inst., the Gas Committee reported that the question of electric lighting had been engaging their attention. When the provisional orders were granted in 1890, the Burnley Corporation followed the practice of other corporations, and adopted a waiting course, but action had now been forced upon them. The Co-operative Stores had intimated that if the Corporation did not take the matter in hand they would take steps to supply themselves, and the Tradesmen's Association had intimated that they also were prepared to do something in a similar direction. The term granted would expire at the end of August, and any outside company would be at liberty to come into the town and establish a central station. It was felt also that if application were made to the Board of Trade for an extension of time it might possibly be refused, as the Corporation had been inactive so long. A deputation from the committee accordingly went to London and gathered a good deal of useful information. They were convinced that the question of electric lighting had now passed the stage of experiment and that electricity would supply a steady, good, and reliable illuminant. Burnley was very favourably situated for laying down the installation. The land to be used for the station was close to the canal and the gas works, and the area to be supplied was exceedingly compact. In response to the circulars which had been sent out, promises representing 1,800 incandescent lamps of 16 c.p. had been received, and the committee considered that that was sufficiently encouraging to justify them in recommending the Council to sanction the calling in of a consulting electrical engineer. If his report was satisfactory, and he assured them that they could supply electricity at about double the price of gas, then the sanction of the Council would be asked to the work being proceeded with. It was proposed at first to provide sufficient power for 4,000 lamps, and the initial outlay of providing plant, building the house, laying the mains, etc., might be roughly placed at £20,000. It was very probable that the experiment would ultimately pay, but for the first year or two they could not expect to get much profit out of it. If it could be made to pay in other towns, surely it could be done in Burnley, which was so favourably situated. The electric light would greatly conduce to the health and comfort of those who had to work by the aid of gas light, and it would form an attraction to the town itself. Alderman Collings observed, in reference to this report, that when the committee had consulted with an electrical engineer they would be fully prepared to give further information.

THE CRYSTAL PALACE EXHIBITION.

At Stand 107, in the North Nave, **Messrs. Croggon and Co.**, of 16, Upper Thames-street, E.C., have a neatly arranged stand of electric fittings, bells, batteries, etc., and a model church tower, with a peal of tubular bells, which proves a great attraction to visitors. Our sketch gives a very good idea of the general appearance of Messrs. Croggon's stand and church. The latter is a model, 30ft. high, of St. Martin's, Guernsey, which the firm have fitted with their system of copper-tape lightning conductors, in the way shown on the model. Care is taken in fixing these conductors to connect all metal work with them. In the belfry is a peal of tubular bells, which are rung by means of current supplied from the Weymersch battery at an adjoining stand. The hammers are worked on the principle of single-stroke electric bells, from a keyboard. The electrical energy required to ring bells like these is very small. Messrs. Croggon state that those at the Palace can be rung with half an ampere, at a pressure of six volts. Country clergymen about to set up a peal of bells might do worse than adopt the tubular variety, with electrically-worked hammers. If the sexton proved obnoxious, the keyboard could be fitted up at the rectory, and the "last bell" timed to suit the parson's convenience.

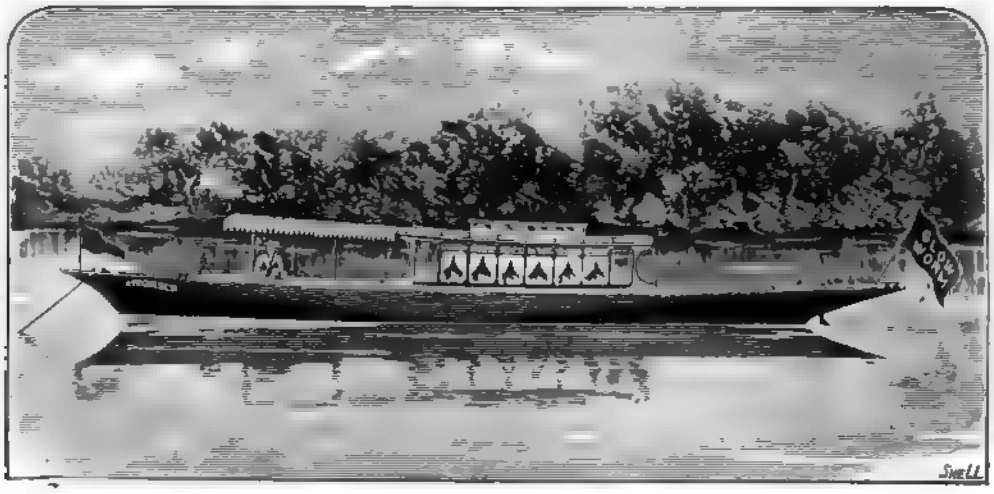
At their stand Messrs. Croggon show a large number of electric bells of all sizes, from the smallest house bell to one for factory use having a diameter of 12in. The firm have introduced a new contact pillar in their bells. This is cast on to its own base, and in this way the risk of shrinkage or shifting which sometimes occurs with the ordinary form of contact, and consequent failure of action, is obviated. Messrs. Croggon have supplied a number of their large bells, single-stroke and otherwise, to mines, factories, and large institutions such as asylums. The mining single-stroke bells, which are used to signal from the engine-room at the pit's mouth to the bottom of the shaft, are worked by an ordinary Morse key. A new design of bell, which obviates the necessity for a drop indicator where several bells are fitted up in one room, has two armatures, one of which is attached to a pendulum visible below the dome. When the bell is rung, the pendulum armature is attracted and suddenly released, causing the pendulum to vibrate for a minute or two, and so indicate the particular bell which has been rung. A new pattern ship's indicator is also shown. In a heavy seaway, ordinary drop indicators are apt to break loose by reason of the ship's motion. The

Sketch of Messrs. Croggon and Co.'s Stand at the Crystal Palace Exhibition.

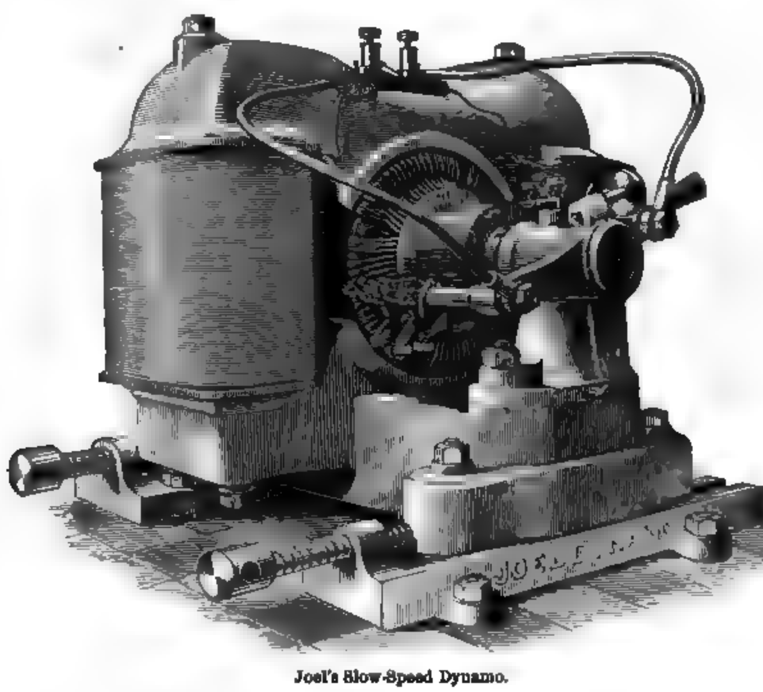
new one is so held by a catch on the armature that it can only fall when a current passes, no motion of the ship having any effect on it. For lifts, a useful indicator is provided which shows the liftman which floor has rung him up; while each floor is provided with an indicator which can be dropped by the man to show he has heard the call and is coming. Messrs. Croggon have brought out a new design of telephone which they sell outright at a very cheap rate, and which, when we tried it at their offices, certainly worked very well. Of the firm's specialities in the way of electric light fittings in wrought iron and copper, there are many elegant and pretty examples at the Palace. Their new pendant for electroliers or single lamps is very simple, and acts well. A ceiling rose contains a roller round which is wound the insulated leads. On pulling the cord a cam is released in the rose, and the roller unwinds until the action is stopped, when the cam engages again and holds the whole in position. The pendant works easily and with certainty. A new wall plug which we noticed on their stand is designed to do away with the objectionable projection noticeable in ordinary wall plugs, and which often leads to their being broken. In Croggon's plug this is obviated by having a push contact-piece at the top, so that the whole thing projects but little from the wall.

The firm have lately carried out several important contracts for wiring and fitting in private houses, as well as hotels and larger establishments, and report that they have their hands full at the present time.

Messrs. Woodhouse and Rawson, as we have previously stated, show, among other exhibits, a model of an electric launch. Many visitors stop and admire this elegant craft, which we understand was built by the Thames Electric and Steam Launch Company. Our readers will remember that Messrs. Woodhouse and Rawson have been particularly active in pushing the merits of electrical apparatus as applied to pleasure boats, and in conjunction with the Thames Company great energy is being put into the business. A rapid glance at the history of such boats is intimately connected with the name of Mr. W. S. Sargeant, who has recently established the company of which he is manager at Eel Pie Island. He designed and constructed the early floating and charging stations on the Thames. He also designed and built the well-known electric launch "Viscountess Bury," 65ft. 6in. by 10ft. 6in. beam, which has been running for the past three years on the Thames as a public pleasure-boat. The charging station at Eel Pie Island will consist of a 100-h.p. engine, transmitting power to two shunt-wound dynamos for charging accumulators. Suitable resistances are arranged that any E.M.F. between 100 and 300 volts, with an aggregate current of 200 amperes, can be obtained, which can be divided into 12 circuits by means of a switchboard. An ammeter can be put into any of the circuits by means of a switch, so that the energy supplied to customers can be measured and charged at a fixed rate. These dynamos will also transmit the current to the motors in the workshops, which will



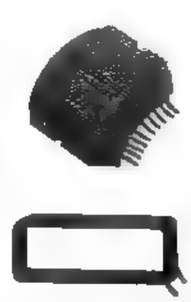
The Electric Launch "Glow Worm."



Joel's Slow-Speed Dynamo.

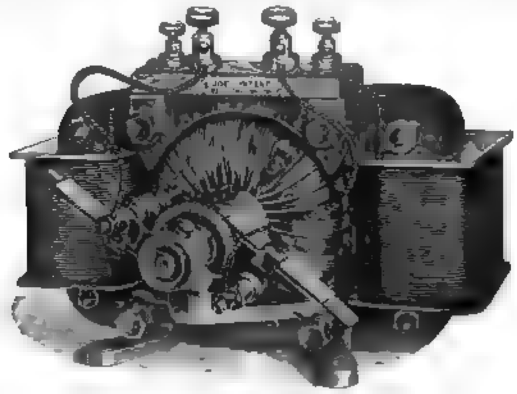
be used to drive the works' machine. Various suitable buildings are being erected for carrying on the business. Adjoining the works is The Island Hotel, and arrange ments have been made to light it throughout by electricity to be supplied from the works.

Joel's Armature and Commutator.



Segment of Coils.

We understand that Mr. Andrew Pears, (of soap fame) has given Mr. Sargeant another order. The new vessel is to be at the next Henley Regatta. She is designed especially for speed, and in appearance will somewhat resemble a torpedo-boat. This is the fourth order Mr. Sargeant has received from that gentleman. The first was the "Pioneer," an electrical launch designed and built by Mr. Sargeant to carry 20 passengers. She is 40ft. long with 5ft. 8in. beam, has a mean draught of 18in., and a displacement of 5¼ tons.



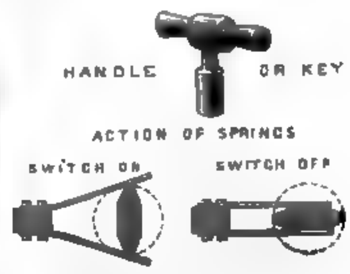
Joel's Motor.

The hull is constructed of three skins, the inner being diagonal, with outside planking longitudinally in narrow widths; the keel, which runs from stem to traffrail, is in one length of American rock elm. There is no dead wood aft; this has been entirely abandoned, thus giving a clear run and obtaining greater efficiency from the propeller. A speed of 8½ miles an hour will be obtained. The second order was the "Pilot," an electric launch designed as a sea-going pinnace, 26ft. 6in. by 5ft. 4in., and constructed to carry 15 people—draught aft 18in., and

Joel's Ammeter.

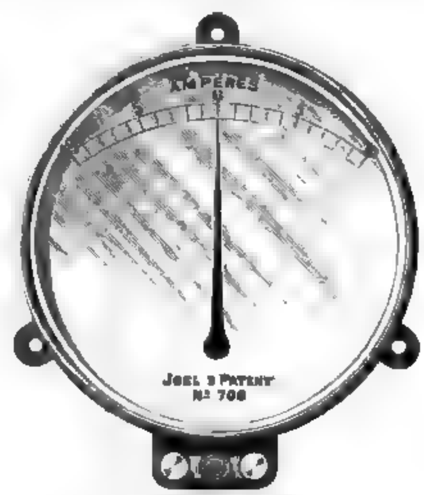
a displacement of 2¼ tons, speed eight miles an hour. The third order being the "Glowworm," which Mr. Sargeant also designed and moulded, together with the working model, now being exhibited on Messrs. Woodhouse and Rawson's stand at the Crystal Palace Exhibition, and which we illustrate herewith. The "Glowworm" is 53ft. long, with 7ft. 2in. beam, has a draught aft of 2ft. 6in., and displacement of 6¾ tons. The accumulators are placed under the seats, and the motor is aft, under the floor.

Joel's Main Switch.



Details of Joel's Main Switch.

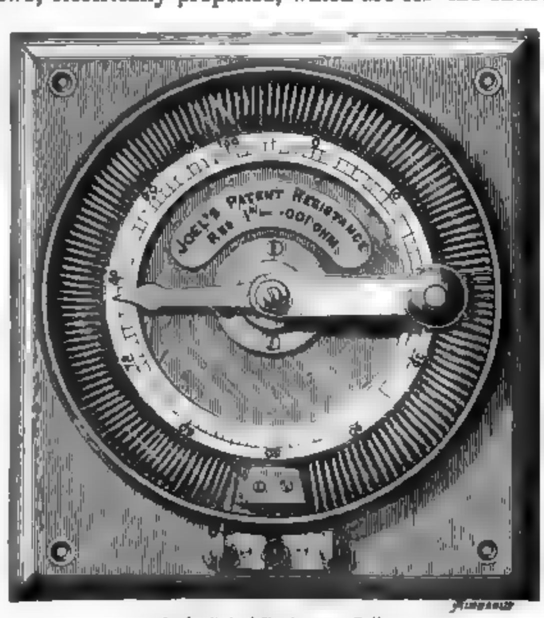
She carries 40 passengers, with a mean speed through the water of 9½ miles an hour, and is lighted as well as propelled by electricity. The potential is 126 volts, with a discharging current of about 35 amperes at full speed, the propeller rotating at 650 revolutions per



Joel's Engine Room Ammeter.

minute. The latter is connected direct with the armature shaft. This vessel has gained the reputation of being the fastest and handsomest electric launch on the Thames.

Amongst other launches in course of being laid down are two, electrically propelled, which are for the entire use



Joel's Spiral Resistance Coil.

of The Star and Garter Hotel, for pleasure parties during the summer months; they will be used for trips to Hampton Court Palace and back. There will be electrical communication between the hotel and the charging station at Eel

Pie Island, so that the launches can be alongside Messum's boat-raft in the time visitors are coming down from the hotel to the river. These launches will be 75ft. long with 13ft. beam, draught aft 3ft. 6in., built in three thicknesses of bright mahogany, with teak fittings throughout, a saloon deck the whole length of each vessel, fitted up with ladies' cabin, and for first and second-class passengers, refreshment bar, w.c.'s, pantries, and everything to meet the Board of Trade requirements; under whose survey they will be built. The saloon will be illuminated with incandescent lamps of 100 volts; port, starboard, and masthead lights will also be electric. The steering-wheel will be placed on the saloon deck amidships, so that the steersman has full view of the river. Alongside the wheel will be the switch, controlling the electrical power, which consists of one single lever, patented by Mr. Sargeant, and is arranged for full speed ahead, half speed ahead, full speed astern, half speed astern. The electrical power will be stored in the same way as the "Viscountess Bury." The accumulators are to be of the latest type in ebonite boxes, and will be supplied by the Electrical Power Storage Company, Limited. The pressure to be used will be 400 volts. The propeller will be connected up direct with

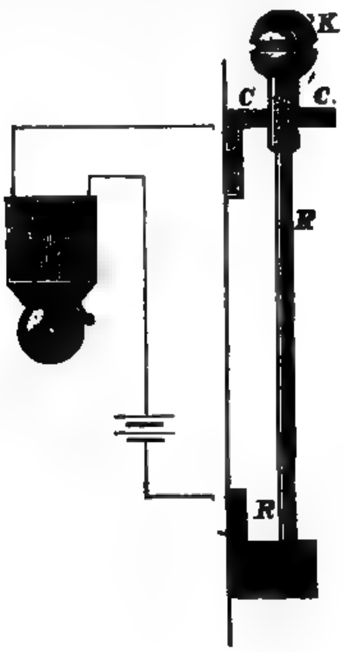


Diagram of Bagnold's Bell-Pull.

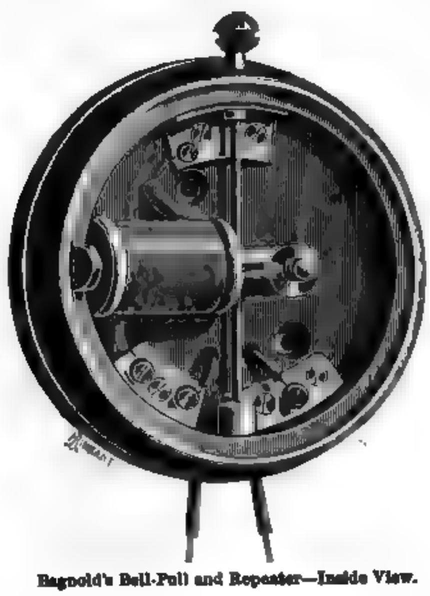
the armature shaft, and will rotate at 600 revolutions per minute. The lines of these vessels are calculated to give a speed through the water of eight knots, the displacement being 16½ tons. They will be running during the summer months from the new lock at Richmond to Teddington, between the hours of 10 a.m. and 8 p.m., calling at the following stations: Steamboat landing stage, Richmond; Messrs. Messum and Sons, the Pigeons and Club House, adjoining Buccleuch House (Sir J. Whittaker Ellis's residence), Eel Pie Island Hotel, Teddington Lock, and then returning.

The stand of **Messrs. Joel and Co.**, No. 157, in the North Nave, contains a good assortment of the apparatus manufactured by the company. The most conspicuous object is the dynamo, which, as it has often been described before, will require only a short description now. The illustration shows the newest type. The complete armature, is also shown in the figures, one representing the armature and commutator with segment of coils removed (showing pulley on end of axle), and the other representing segment of coils from armature and single armature coil. The armature is built up of sections or groups of laminated iron plates of segmental shape. These sections interlock, fit into each other, and are fastened by bolts to spokes, and thus form the rim of the wheel. The insulated wire coils are separately wound and are threaded on the core sections. The ends of the coils are connected in a special and convenient manner to the commutator, and can be quickly disconnected. The mechanical details are worked out to secure great simplicity, and to enable the dynamo to be easily and quickly taken to pieces and put together again without special skilled labour. This is useful on board ship, in the country, and other places where an easily repaired machine is necessary. For use on board ship a spare set of armature coils is provided, in the event of damage by steam, water, or any unavoidable cause, such as is frequently the case owing to the cramped space usually available for the electric light machinery; the engineers can then easily repair the machine and put in the new coils if necessary. The annexed illustration shows one of Joel's motors, being the result of many years of experiment and testing. They are made to run with either continuous or alternating currents.

Bagnold's Bell-Pull Without Cover.

Hitherto, the want of such an alternating-current motor has been the great drawback to the extension of the alternating-current supply system, and it is considered that this motor will prove of immense importance in the future of electrical supply enterprises. The special feature of the motor is the use of very thin laminated iron in the fields and armature. The field magnet cores and poles are made in one piece of thin stampings of iron of the exact size and shape, and any number of these (according to the size required, are bolted together and thus make up the iron frame without any after tooling, and having the greatest possible magnetic efficiency. A number of these motors have been made and supplied, and are said to give an efficiency of 90 to 92 per.cent.

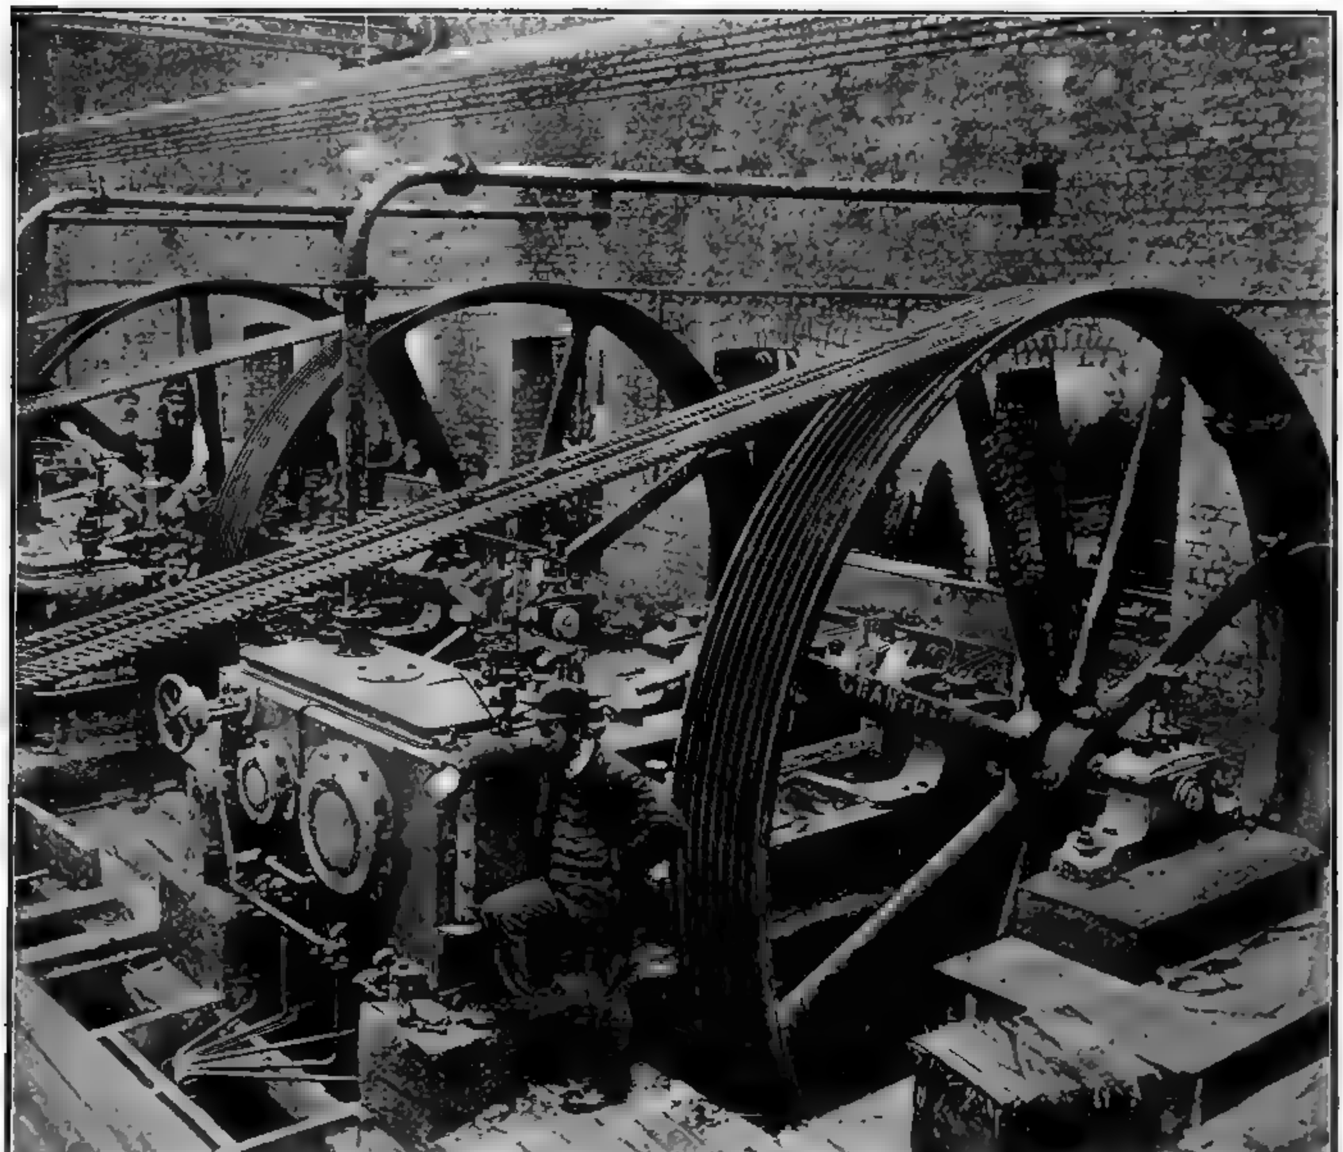


Bagnold's Bell-Pull and Repeater—Inside View.

Messrs. Joel and Co.'s patent main switches are made with porcelain backs and glass fronts with detachable key. We also illustrate these. The moving parts are completely closed in, and a key is needed for operating the switch. The contact bar is made of hard-rolled brass, and is slit so as to form a springy comb at the ends; the object being to make as many contact points as possible. These contacts pass under sparking shields fixed upon the terminal blocks. The switch has a double break; the sudden break being obtained by two flat steel springs, which press upon a stem of an elongated oval section, so that the springs are compressed when the switch is on and cause the contact bar to leave the terminals suddenly.

The makers claim that one of the special advantages of this type of switch is that it is completely protected from dust and interference, while its action can be readily observed through the glass case. Messrs. Joel and Co. also exhibit their patent ampere-meters, suitable for use with storage battery installations, as shown, and their central station engine-room ampere-meter, for use with arc lamp and continuous-current series circuits, and also their spiral resistance for adjusting circuits in central stations and many other purposes.

An improved bell-pull, which deserves to have a widely extended sale, if not to entirely supersede the "push-button," is shown on **Messrs. Siemens's** stand. For over 40 years the familiar push-button used in conjunction with electric bells has remained unaltered, except as regards the artistic design of its exterior, notwithstanding that considerable inconveniences are connected with the use of this simple household fitment. The ordinary push-button must be pressed in a direction at right angles to the surface of the wall or other support to which it is fixed. Again, the contact made is not always of the best; it is essentially a "butt" contact, and possesses little or no self-cleaning powers. When definitely established, say, in the immediate neighbourhood of a bed, or of an office or dinner-table, it is difficult to actuate these push-pieces from any other position. Pull-pieces have been devised, but these need to be pulled, as a rule, in one particular direction; flexible cord connections are also used, connected to "pear" pushes, but these again are seriously liable to derangement, and may be said to contain the elements of their own destruction. Generally speaking, there are many instances of daily occurrence in which the shifting of a bed, of an invalid's chair, or of a writing-table necessitates the advent of the electric bell-hanger and the moving of the contact-piece from one position in the room to another. In order to obviate these inconveniences, Messrs. Siemens Bros. and Co. are now supplying, under license from Major Bagnold, a simple and effective arrangement of bell-pull which, no matter where fixed in a room, can be easily actuated from any point in that room by attaching a thin cord, and leading this cord away in the desired direction; a very slight pull on the cord is necessary to make contact and ring the bell. In the diagram of the bell-pull and connections shown, an elastic rod of steel, R R, is set vertically with its lower end firmly fixed into a brass block, B; on its upper end is screwed a brass knob, K, the shank of which passes through a brass ring, C C, the conducting wires are attached to B and C. A slight pressure applied to K in almost any direction other than in that of the axis of the rod, R R, will deflect that rod, and cause the shank of the knob to touch the ring, C C, and make the necessary contact. This contact needs no silvering or platinising, as the knob can at any time be given a circular motion, which will clean the contact surfaces and ensure the establishment of the circuit. If it be desired to actuate this contact-piece from a distance, it is only necessary to tie a fine cord round the horizontal groove on knob, K, and this cord can be led off in any required direction, such as to a bed, a chair, or a dinner-table.



Engines at Sydenham Electric Light Station.

This bell-pull is made in various patterns and sizes. It can also be conveniently combined with a sound-repeater. When a bell-pull or push is actuated, it is often of great importance to be able to know that the electric bell is rung. The other illustrations show a new form of sound-repeater,

which, combined with the contact previously described, makes a most convenient and efficient fitting for this purpose. The repeater is shown both complete with the nickelled steel bell dome, and without the dome. When the latter is screwed on, one pole of the electromagnet is presented to the sound-boss of the bell; as soon as the contact is closed and the circuit is intermittently interrupted at the distant "chattering" bell the bell dome of the repeater is set into vibration, and gives out a clear ringing sound sufficient to indicate that the distant bell has acted, but not so loud as to be inconvenient to the occupants of the room in which the contact is made. The above-described system of ringing a steel bell magnetically can be applied in other ways. Thus, supposing it is desired to actuate several bells in series on one circuit, one of these can be an orderinary "chattering" bell and the others can be simply "sound-repeaters" without contacts. No difficulty of adjustment is experienced as in the case when ordinary chattering-bells are joined in series.

SYDENHAM ELECTRIC LIGHT STATION.

Continuing our illustrations of this station, we give this week views taken from photographs of the engines and dynamos. As we have previously said, the engines were built by Messrs. Hornsby and Sons, of Grantham; the dynamos at the works of the Electric Construction Corporation, Wolverhampton. These generators are each designed to give an output of 80 amperes at a pressure of 1,080 volts, with a speed of 370 revolutions per minute. The armatures are drum-wound. The magnets have a resistance of 9·5 ohms when hot, and are excited with a current of 14·2 amperes from a small machine driven by rope gear from a pulley keyed on the main shaft, as shown in the illustration. The generators themselves are also driven by rope gear, the pulleys being carried between two bearings. A coupling between pulley shaft and armature allows of the latter being removed without taking off the ropes. Each machine weighs 15 tons.

LARNE.

It is the simple straw that tells which way the wind blows, and notwithstanding the immense efforts to keep the real wire-pullers in the background, some simple matter ofttimes enables us to trace home an attack upon the industry. We rather admire plucky combatants, but the man or men who are constantly trying a stab in the dark are neither worthy of sympathy nor commiseration. The attack of the gas interest upon electric lighting is scarcely or never straight. Puppets are put up and the wires pulled, the real organisers remaining in the background. We have no fault to find with gas for attacking electricity; rather it is the duty of those interested, but they might make an effort or two by means of pitched battles instead of lying in ambush. Distinctly, we do not believe in all the rubbish talked about gas not suffering from the introduction of electricity. It has got to suffer whatever may be said to the contrary, and the sooner the fact is recognised the better for all parties concerned. The coaching interest suffered from the introduction of steam. It is the natural law. Horses, indeed, were turned to other purposes, so may gas, and attention might well be directed to these other purposes. The *Larne Times* of Feb. 9 devotes almost an entire page to the report and consideration of a meeting of ratepayers, called to "give expression to the unsatisfactory lighting of the town; and also as to the forty-two years' agreement entered into between the Commissioners and Messrs. Gordon and Co." Immediately upon the result of the poll at this meeting being known, a voice was heard to say: "The gas promoters have lost the day"—hence the straw pointing to the real opponents of the electric light at Larne. The brief history of the whole matter may be given in a few words. As is well known, scores of local authorities have for years been off and on discussing the possibilities of electric lighting, and among others the Larne Commissioners. Messrs. Gordon and Co. have been very energetic in bringing plans for lighting before many authorities, and, again among others, before the Larne Commissioners. This activity succeeded in convincing the Commissioners that not only was such lighting practicable, but in this particular place compared favourably, as regards cost, with gas. As a result, the Commissioners entered into a three years' agreement with Messrs. Gordon and Co. The work of the installation was proceeded with, and as time was an object, temporary arrangements were made; the final permanent arrangements have yet to be finished. Here, then, was the chance of opponents. They laid hold of what they termed the unsatisfactory state of the lighting. Yet little stress was laid upon this at the meeting, while the fiercest battle raged round the "forty-two years' agreement," which is non-existent. Mr. Picken, a dissentient commissioner, was the leader of the opposing faction. He undoubtedly is a brave man. His audience was hostile, yet he put forward his case, reminding us of him whom Horace describes in the lines:

Si fractus illabatur orbis,
Impavidum ferient ruinæ.

In the end, the opponents of the electric light were beaten by seventy-four votes to forty-eight, and we trust the contractors will now go on their way undisturbed, complete the permanent apparatus, and by its success induce the ratepayers to go in for what one described is very much wanted—more light.

We are glad to find that Mr. Fullerton, the chairman of the Commission, condemned without qualification the argument that so crudely was the agreement drawn that it contained no clause to prevent the contractors going away and leaving the town in utter darkness. Electrical engineers will probably agree that the difficulty is in getting a foothold, and that after having invested eight or ten thousand pounds to put down an installation, there is little likelihood of abandoning the work. Before entering upon a contract, it may be assumed that the engineers carefully considered the probable income, and did not enter into a binding agreement till they were certain of their position. Opponents seem to consider that our Cromptons, our Gordons, and the managers of various firms and companies are not business men. We can assure them that few keener business men will be found in any industry than those who are now the ruling spirits in electrical engineering. It must be remembered, too, that it would not pay a firm of any repute to put its hand to the plough and afterwards turn back.

CANTOR LECTURE—No. 3.

Prof. Forbes at the commencement of his third lecture spoke in terms of great praise of Mr. Tesla's recent lecture, and took the opportunity of having a fling at some technical journal which had incurred his censure on the question of the practical man *versus* the scientific. It has been our misfortune to occasionally have a tilt at the arrogance and conceit of some so-called scientific men, but in this case we do not plead guilty, yet it may be assumed the guilty party will have little difficulty in combating Prof. Forbes's views. Mr. Tesla starts as a practical man, with a definite, practical end in view, and this distinguishes him, and others like him, from the inane dandy who experiments with the object of finding out something somehow. One millionth of such investigations prove useful to mankind—the rest are waste labour. Mr. Tesla's aim is, if we read him aright, to give us artificial sunlight—it may be a less powerful light, but softer, and as diffused over those areas in which the influence is at work. Passing from Mr. Tesla's work and the practical man, Prof. Forbes agreed upon the great value of oil as an insulator. The late David Brooks was the apostle of this system. For twelve or fifteen years before his death we held constant communication with him on the subject. Oil has always seemed to us the ideal insulator, and we regret Brooks is no longer among us to see that at length his views are becoming more common. The lecturer passed in review the necessity of so designing stations that big engines should not be running to waste, but rather, while obtaining economical engines, multiplying them and bringing them into use as the load comes on. He pointed out the difference between distribution of power and distribution of light, and, although we do not agree with all his conclusions, it must be admitted that a great difference exists. The lecturer concluded with a brief examination of the rotary-current system, and reference was made to recent experiments carried out with the apparatus now in London.

MR. TESLA AND VIBRATORY CURRENTS.

The lecture given by Mr. Tesla on Wednesday last week before the Institution of Electrical Engineers, and repeated on the Thursday before the Royal Institution, will live long in the imagination of every person in the brilliant scientific audiences that heard him, opening as it did, to many of them for the first time, apparently limitless possibilities in the applications and control of electricity. Seldom has there been such a gathering of all the foremost electrical authorities of the day, on the tiptoe of expectation to witness the experiments, details of some of which had already been given to us from the other side of the Atlantic, but of which no written account could convey the true significance and beauty. Long before the hour of meeting the hall was crowded, and Mr. Tesla was watched throughout with the keenest interest as he adjusted his apparatus quivering with lightning-like discharges, and now lighted a vacuum tube by grasping it in his hand, now brought to incandescence the filament of an ordinary lamp attached by a single wire, there rendering the air in the interior of a large ring luminous with flame, or sending streams of light from wires stretched over the audience, and, most fascinating of all, after electrifying the whole space of air between his table and an iron plate above him, waving a luminous tube in his hand totally unconnected to any wire whatever. It was, indeed, curious to see the most prominent and noted electricians of the day as interested in Mr. Tesla and his experiments as any child with the first friction machine, asking whether it was safe to do this or that, to touch the wires, and whether they might be allowed to try. For full two hours Mr. Tesla kept his audience spellbound, with easy confidence and the most modest manner possible displaying his experiments, and suggesting, one after another, outlooks for the practical application of his researches; and it was difficult to realise that this memorable lecture was the second only that he had ever delivered. Even at the end Mr. Tesla tantalisingly informed his listeners that he had shown them but one-third of what he was prepared to do, and the whole audience, after Prof. Ayrton had proposed the vote of congratulation and declared the meeting over, yet remained in their seats unwilling to disperse, insisting upon more, and Mr. Tesla had to deliver a supplementary lecture.

It is not for us here to describe the lecture in its details, as a full and illustrated report, revised by Mr. Tesla, is being prepared for the *Journal* of the Institution of Electrical Engineers, which will appear in due time, and containing much even that could only be glanced at in the lecture itself, and this will be the proper material for electrical engineers to fully discuss. But it may be allowed us to dwell a little upon the scientific *modus operandi*, and give certain particulars which our readers, no doubt, are looking for with interest.

In the first place, it may be stated, as Mr. Tesla mentioned, but which hardly seems to be realised, that practically the whole of the experiments shown were new, and had never been shown before, and were not merely a repetition of those given in his lecture in America. That of lighting tubes in an electrostatic field and of bringing filaments to incandescence on a single wire were shown before, and being of the most importance, naturally were not left out. But all the other experiments, together with most of the apparatus itself, was novel, and was supplementary to that of his American lecture.

In the next place, it is important to understand—as also stated by Mr. Tesla at the time, but hardly, perhaps, yet

realised—that nearly the whole of his experiments and effects were produced by means of an ordinary alternating current from an ordinary commercial alternating-current dynamo—such, in fact, as can, in many places, be obtained from a central supply company's mains. These effects can be, and were, brought about also by means of the currents from his special alternator, but the chief benefit of the use of this alternator is in being able to obtain perfectly harmonious currents of a known number of alternations per second, and in research work this knowledge is evidently of immense value.

Without going deeply into the detail or the theory of the working of the apparatus used, it is seen, therefore, that the effects are produced by using an alternating current, either generated direct at high potential and with high frequency of reversal per second, or ordinary currents converted into such currents. Mr. Tesla termed these currents "alternating currents of high potential and high frequency," but in the same way that the term rotary current (first proposed, we believe, in these columns) has now gained acceptance to indicate alternating currents varying in phase for producing a rotating magnetic field, so we may, perhaps, venture to use the term "vibratory currents" for those of high potential and high frequency. To generate vibratory currents from an ordinary alternating-current circuit, Mr. Tesla uses first an ordinary transformer in oil to transform upwards; the secondary current from this he passes into a second transformer having in its circuit a magnetic spark interrupter, and from the secondary circuit of this second transformer (which it may be noted is of comparatively thick short wire) he obtains discharges in all respects similar to those of the great induction coils, but of very high frequency. Connecting this circuit to a properly-adjusted condenser, in his case a set of Leyden jars, a surging effect is produced on the currents, which raises the frequency of vibrations from 25,000 or so per second to some millions per second, and the potential to some hundreds of thousands, or even, perhaps, millions of volts. The frequency in the case of the use of the Tesla dynamo can of course be accurately determined. The potential, it seems, cannot be accurately arrived at by calculation, or, rather, the calculation does not give an accurate result correspondent with the actualities achieved in these effects—a fact, as we shall see, that may have very important theoretical results upon the wave theory of electricity.

Having at command a vibratory current of this nature, the results shown by Mr. Tesla were the first outcome of continued and careful experiments. Not only does the molecular bombardment of the molecules of highly-exhausted gases in vacuum tubes show phosphorescence, but gases at low states of exhaustion do the same, and even ordinary air at ordinary temperature, as Mr. Tesla showed at his lecture, where the space between two concentric rings glowed with discharge like a vacuum tube itself, while the vacuum tube glowed when at some considerable distance from the plates to which the two poles were connected. In this manner, by vibrating the air molecules at speed correspondent to that of the vibration of light, phosphorescent effects could be shown with ease. Phosphorescence, Mr. Tesla explained, he regarded as incandescence in another form. Ordinary incandescence accrues after the filament has passed interiorly from the state of cold to that of intense heat; while if we regard a bombardment of molecules with sufficient intensity upon the surface of a material, we may conceive an infinitesimal film of that material rendered continuously incandescencent without the trouble of heating the whole—in a word, we obtain the light vibrations without passing through the whole gamut of heat vibrations—which has long been the electrical engineer's most ardent desire. To obtain a concrete idea of the difference between the ordinary alternating current and the vibratory current, we might imagine the first as a large ordinary steam engine reciprocating at 100 revolutions, while the second becomes a smaller and smaller material engine as its reciprocations mount from hundreds to thousands, or hundreds of thousands, in the same unit of time. In the latter we have the greatest efficiency with the smallest of first outlay.

We need not go further into the detail of the experiments shown by Mr. Tesla based upon these considerations, as they will be given, as we have said, fully in his paper. We merely mention here that Mr. Tesla hinted at illumination of houses without wires, transmission of light and power to a distance without wires, the synchronising of various wave-lengths for multiplex telegraphy without wires, the use of motors with but one wire, or even possibly without any, and the recovery of the solar energy radiated around us direct—"gearing," as he said, "our motors to Nature's wheels."

He demonstrated that our ideas upon dielectrics required modification, and that it was a mere question of potential to make every material or gas a conductor. It was shown that the interposition of a plate of ebonite, in fact, facilitated, rather than otherwise, the discharge. He showed that the vanes of the Crookes radiometer would rotate under the influence of his vibratory current, a rotation, curiously enough, the reverse way to that induced by light. We believe a similar result was first pointed out in a paper read before the Institution at Edinburgh by Mr. A. R. Bennett.

Mr. Tesla incidentally showed that the glow discharge in a tube under certain conditions would revolve and then become extremely susceptible to the feeblest magnetism, and he hinted that possibly by this means the rapidity of transmission of telegrams through submarine cables might be greatly increased.

A word remains about one or two personal and scientific problems. In the first place, it will be interesting to know Mr. Tesla's own ideas as to the future practicability of his researches—ideas which, of course, will have to await their fulfilment for some time for actual application in practice. The question naturally arises, How can the vibratory current be applied to lighting? Should we expect to have incandescent or phosphorescent lamps of a pattern similar to those we know in the Edison-Swan lamps or the Geissler tubes, or should we expect rather to discover a practical means for rendering the whole mass of the air in a room softly and beautifully phosphorescent? Both, Mr. Tesla thinks, if we understand him aright, may occur, but he looks certainly to the possibility of the last and most fascinating project. Further, many of those who witnessed his experiments must have asked themselves a question as to the danger of the vibratory currents, which Mr. Tesla handled so unconcernedly. We took an opportunity of enquiring of Mr. Tesla with reference to this point, how, indeed, he came to dare to take the current through his body? It was the result of a long debate in his mind, it appears, that caused him to attempt the experiment. Reason and calculation showed him that such currents ought not to be dangerous to life any more than the vibrations of light are dangerous. The self-induction and frequency of alternation should be too great for any current to pass, and for a current to be dangerous a certain quantity must pass. Conceive a thin diaphragm in a water-pipe, with to and fro piston-strokes of considerable amplitude the diaphragm will be ruptured at once. With reduced strokes of the same total energy the diaphragm will be less liable to rupture, until with a vibratory impulse of many thousands per second no actual current flows, and the diaphragm is in no danger of rupture. So with the vibratory current—yet in spite of reason and analogy it was with the feelings of a man about to plunge from Brooklyn Bridge (as one might well believe) that Mr. Tesla took his first shock from his apparatus. The result justified his daring, and he suffered no more than a slight shaking in the arms. A spark, of course, passes and this punctures the skin and causes a slight burn, but that is all. This can easily be avoided by holding a conductor of suitable size in the hand and receiving the shock upon that.

There lurks in one sentence of Mr. Tesla's lecture a statement which will cause much discussion in high scientific circles. We shall not further refer to it here than to say, that if the voltage obtained is not exactly calculable from the data laid down of the condenser and the frequencies—if, in a word, the result is not approximately that calculated, but considerably lower, then this would certainly seem to show that Hertz's experiments and results are not final, and the

way is open to further experiments and research in this direction.

From the way in which Mr. Tesla alluded feelingly to the impulse in research given to himself from perusal of Crookes's experiments in high vacuum, the effect upon students and scientific men generally of the publication of his own promising researches must be great. We can only hope that others, now that the way has been shown, will take up the work, and before many years have passed produce for the world at large the thoroughly practical outcome hinted at in the "wonder-full" lecture by Mr. Tesla at the Royal Institution, on Wednesday, the 3rd of February, 1892.

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

III.

(Continued from page 67.)

Measurement of Electrical Resistance.

Resistance.—The retarding influence exercised by any substance to the free passage of an electric current is technically known as Electrical Resistance. Speaking generally, if the sectional area of any homogeneous metallic conductor is uniform, then its resistance is proportional to its length, provided its temperature does not vary; and further, if its length remains constant, then its resistance varies inversely as its sectional area, the temperature again remaining constant. As a rule, if a metallic conductor is heated its resistance increases. This is true of all the best-known conducting substances with the notable exception of carbon, whose resistance decreases as its temperature rises.

The reverse property to Resistance is called Conductivity, the conductivity of any conductor being a measure of the freedom which it affords to the passage of an electric current. Thus the greater the resistance of a conductor the less is its conductivity, and *vice versâ*.

Absolute electrical non-conductivity—that is, infinite resistance—is unattainable, and similarly, perfect electrical conductivity, or absence of resistance, is unknown. If all known substances were to be arranged in order of their conductivities, we would find the metals headed by silver and copper at the top of this list; carbon, graphite, and some solutions of salts and dilute acids, about the middle; and such substances as guttapercha, shellac, and dry air, at the bottom.

In the following table, chiefly due to Culley, there is given a list of the more important substances arranged according to this plan. Culley has further divided his substances into three classes: conductors, semi-conductors, and non-conductors or insulators; but this division is of course entirely arbitrary.

Table 2.—*List of Substances arranged in order of their Electrical Conductivities* (Culley).

Good Conductors.	*Semi-Conductors.*	*Insulators.*
Silver	Carbon	Wool
Copper	Graphite	Silk
Gold	Acids	Sealing Wax
Aluminium	Saline Solutions	Sulphur
Zinc	Sea Water	Resin
Platinum	Melting Ice	Guttapercha
Iron	Pure Water	Indiarubber
Tin	Stone	Shellac
Lead	Dry Ice	Paraffin
German Silver	Dry Wood	Vulcanite
Antimony	Porcelain	Glass
Mercury	Dry Paper	Dry Air

If a material is required which will carry an electric current with as little resistance as possible, it would be chosen from as near the top of this list as is compatible with cost of material, suitability for the special work, and various other conditions which will readily suggest themselves; and similarly, a body which is to act as an insulator would be chosen from near the bottom.

As a result of the foregoing considerations, the laws governing the electrical resistance of all metallic bodies may be stated as follows:

1. The total resistance of a uniform metallic conductor at any fixed temperature is directly proportional to its length, if its sectional area remains constant.

2. The total resistance of a uniform metallic conductor at any fixed temperature is inversely proportional to the area of its cross-section, if its length remains constant.

3. The total resistance of a uniform metallic conductor of any given length and cross-section at any fixed temperature is directly proportional to the specific resistance, and inversely proportional to the conductivity (taken at that temperature) of the material of which it is composed.

Specific resistances are usually expressed as the resistance in ohms, or microhms, of a cubic centimetre of the material, at 0° C. or 32° F. Specific electrical conductivity is the reciprocal of specific resistance.

If R represents the total resistance of the conductor in ohms,
r „ its specific resistance, or the resistance in ohms, of a cubic centimetre of the material,
L „ its length in centimetres,
and A „ its sectional area in square centimetres;

$$\text{then } R = \frac{r\,L}{A}.$$

Electrical resistances, however, are not usually obtained in this way, but by comparison with other conductors of known resistance (such as graduated coils of German silver, platinoid, etc., suitably mounted in a resistance-box) by one or other of the methods to be described later.

In the course of these articles constant reference will be made to specific or comparative resistance, conductivity, and insulating properties, of the various materials employed in the manufacture of electrical instruments, or of the substances for the determination of whose characteristics, delicate measuring instruments are employed. The following table, compiled from Dr. Matthiessen's experiments, gives a list of the more important conducting materials, in column 1; their specific electrical resistances in B.A. microhms (one microhm equals one-millionth of an ohm), in column 2; their approximate comparative resistances, taking the resistance of annealed silver as unity, in column 3; and their approximate percentage increase of resistance per degree centigrade increase of temperature, in column 4.

Table 3.—Resistances of Metals and Alloys at 0° C. (Matthiessen.)

Name of Metal.	Specific Resistance.	Comparative Resistance.	Percentage Increase of Resistance per deg. Cent
	B.A. Microhms.		Per cent.
Silver, annealed	1·521	1·00	0·377
„ hard-drawn	1·652	1·09	„
Copper, annealed	1·616	1·06	0·388
„ hard-drawn	1·652	1·09	„
Gold, annealed	2·081	1·38	0·365
„ hard-drawn	2·118	1·39	„
Aluminium, annealed	2·945	1·94	„
Zinc, pressed	5·689	3·75	„
Platinum, annealed	9·158	6·08	„
Iron „	9·825	6·80	„
Nickel „	12·60	8·30	„
Tin, pressed	13·36	8·80	„
Lead, pressed	19·85	13·60	0·387
Antimony, pressed	35·90	23·65	0·389
Bismuth „	132·7	87·20	0·354
Mercury, liquid	96·19	62·50	0·072
1 platinum + 2 silver, alloy	24·66	16·10	0·031
German silver, alloy	21·17	14·87	0·044
2 gold + 1 silver, alloy	10·99	7·22	0·065

(To be continued.)

INSTRUCTIONS FOR WORKING CROSSLEY'S "OTTO" GAS ENGINES (NEW TYPE).

(Extract from "First Principles of Electric Lighting.")

These engines are a great improvement on the slide-valve type, but at the same time it is necessary, for their safe management, that careful attention be paid to the instructions herein given.

The new ignition apparatus supplies the long-felt want of a reliable hot-tube ignition, and when kept in fairly good order and the instructions strictly adhered to, it is free from danger to the attendant.

Before Starting.—See that all the bearings and working parts are perfectly cleaned and well oiled, and that water is supplied to the cylinder-jacket.

Next, move the ignition-valve in and out by hand to make sure it is not sticking.

Starting.—1. The gas flame in the chimney should be lighted *ten minutes* before the engine is required to work. See that the flame does not light back and burn at the air-holes in Bunsen burner.

2. A blue flame should just surround the tube in centre of chimney, *and no more*, and should not burn above the top of chimney.

3. The engine must not be started until the tube has arrived at a bright red heat.

4. Move the handle on cams at side of engine *as far as it will go to the left* to release compression, and to put the ignition bowl on late safety cam. This is necessary for safety, as well as to make starting easy. After starting, reverse this handle when the engine has got up speed. *Don't leave it half-way.* In the smaller engines no handle is required, but the bowl of exhaust cam is to be moved opposite a small secondary cam, and held in position there by a pin until the engine has started.

It is *dangerous* to put one's foot on the flywheel arms in starting the engine, as with "tube ignition" the engine, *if out of order*, may turn in the wrong direction at the first explosion. Lay hold of wheel on *outside, not inside* next crank of engine.

Lubricating.—Regulate the supply of oil to the crank-shaft and connecting-rod by means of the worsted trimmers. Take the trimmers out when the engine has stopped, to prevent waste of oil, also renew the trimmers occasionally.

Oil.—It is always advisable to use oil supplied by the makers; buying oil indiscriminately nearly always leads to clogging, premature explosions, and consequent loss of power, and the mistake is not found out till the mischief is done. It should be borne in mind that the oil used in a gas engine has to stand flame temperature, and that, therefore, oils of low flash-point are not suitable, however good they may be for ordinary purposes.

The Ignition-valve.—The ignition-valve is a small brass valve, placed in some cases below the chimney, but usually alongside it. When taken out, it will be found to have a projecting end $\frac{5}{16}$in. diameter. This closes the hole leading to the cylinder during compression of charge. If it becomes too slack in this hole—permitting too great escape—it should be replaced. Interchangeable duplicates are kept by the makers. *The proper stroke or lift of this valve is $\frac{5}{16}$in.* When putting in a new one see that it has this stroke.

When wear of the cam and roller reduces this stroke to $\frac{1}{4}$in., the worn part should be changed at once, and the original stroke regained; this is *necessary for safety*, as, if neglected, the engine may reverse at starting, turning back sharply, and so endanger the attendant.

A slight escape is intended to take place through the vent-hole, in the casing, near the flange of this valve—this is necessary for safety. The hole is to be kept clean to allow of this escape; if the escape becomes too great through wear it is not to be stopped by filling up the vent-hole, which would be dangerous, but by renewing the valve if the head is worn, or, if not, by grinding in the mitre valve part.

Cleaning Ignition-valve.—The ignition-valve should be taken off weekly and cleansed with an oiled rag—*not with emery*; oil it at both ends when working.

When replacing the *ignition-valve gland in ignition block* be careful to tighten up both nuts equally, so that the valve spindle may slide up and down quite freely.

Ignition-tube.—A new ignition-tube should be put in after every 30 to 60 hours' work, as after that time they are liable to break if of wrought iron. The makers, however, supply tubes of special metal that may last 12 months.

A spare tube-holder is sent with every engine, which should always be kept at hand with a new tube in it ready for insertion in the chimney. The tubes must be firmly screwed into the holder, so as not to leak at the joint; proper tools for removing old tubes and inserting new ones are sent with each engine.

Chimney.—The perforations in the top of chimney must be kept clear. If looking down the chimney while the engine is working, shut off the cylinder gas supply, lest an accidental escape should blow dust into the eyes.

Cleaning the Cylinder.—The piston should not be taken out unless cleaning or a new ring is needed. When it is taken out, scrape out all dirt that may be found at the back of cylinder, and thoroughly clean and oil the cylinder before replacing the piston.

The big end of the connecting-rod has only to be uncoupled to enable the piston to be drawn out. The joints of all the rings should be at the *bottom of the piston.* When replacing the piston be careful that the steady-pins in the grooves fit into the gaps in the rings, or the rings may be broken when pushing in the piston.

When wear of the piston-rings occurs, *change the inside ring only at first.* Do not use force in replacing the piston.

Valves.—The exhaust, admission, and gas valves should be examined occasionally, and, if necessary, ground into their seatings with emery powder and oil. As mentioned in the instructions for the slide-valve type engines, too much attention cannot be paid to the condition of the *exhaust-valve*, and the remarks thereon apply equally to the slideless type of engine.

Water-tanks and Cooling.—Never work the engine without water in the jacket of the cylinder. The water-tanks must be kept full by a ball-cock. If the cylinder of the engine becomes much hotter than the water in the tank, the circulation is obstructed, and should be attended to.

The water-pipe from top of cylinder to top of tank must slope upwards at every point. The pipe from the bottom of cylinder to the bottom of the tank must have no bends where air can lodge.

Frost.—If the engine is exposed to frost whilst not working, burn a gas light under the cylinder *to keep the water in the cylinder-jacket from freezing*, or the water may be drawn off. *Neglect of this precaution may cause breakage of the cylinder-jacket.*

Dust and Dirt.—Protect the engine as far as possible from dust and dirt, and take care that it does not draw its air supply from a heated or impure source.

Gearing up Side Shaft.—Although in erecting these engines special instructions are given to gear up the wheels to the marks on the teeth, "O O," it is advisable to call attention to this point, as mistakes are often made in putting these wheels together.

AN INTRODUCTION TO QUALITATIVE CHEMICAL ANALYSIS.

BY BARKER NORTH, ASSOC.R.C.SC. (LOND.),

Joint Author of "Introductory Lessons" and "Hand-book of Quantitative Analysis."

[When Prof. H. E. Armstrong spoke at the Society of Arts on Mr. Robertson's paper on "Secondary Batteries," he deplored the lack of chemical knowledge among those who had the care of such batteries. The columns of a technical paper cannot contain all the information required on these subjects, but we herewith commence a short series of articles by Mr. Barker North, intended to serve as a general introduction to the study of qualitative analysis.—ED. *E. E.*]

In the following articles it will be assumed that the student has already obtained a knowledge of elementary chemistry, and as the latter is, as a rule, now taught in a more practical manner than heretofore, it will be taken for granted that the pupil has already obtained experience in the experimental portion of chemistry, such as the prepara-

tion of gases and demonstration of their properties. It is too often the case, however, that when a student has acquired skill in this branch of the subject, that he is told to at once commence the reactions of the various metals without any previous knowledge of the tests he is applying, and he thus works for a considerable time in the dark, as it were, whereas if special attention had been paid to teaching him systematically how to apply the various tests by well-chosen examples, much of his valuable time would have been saved, besides which he would have obtained a much better grasp of the subject.

It is therefore proposed to make the following a comprehensive survey of the operations which the student will have to perform in the various processes of analysis, and by working through the examples given, and making notes as he proceeds, he will acquire that manipulative skill in the carrying out of reactions which is essential for successful after-work.

Qualitative Analysis is that branch of chemical science by means of which we ascertain the nature of bodies—that is, the constituent or constituents of which they are composed. This is done by applying reagents or chemicals of known composition under certain conditions to the substance under examination; and by observing the changes which take place, such as the formation of an insoluble substance, change of colour, etc., the absence or presence of any particular element or compound may be inferred.

There are two methods of analysing in qualitative analytical chemistry—viz., by dry and wet reactions. The latter is the more reliable, and for this reason the former is too often neglected; yet the dry method will often give us the "cue" to the composition, and in some cases will even tell us the whole of the constituents present in a substance.

The dry method will be treated of first, as it should always precede the wet, in order that the latter method may be adapted, if possible, to the information thus acquired.

Chemical Manipulation—Dry Reactions.

In the Closed Tube.

This should always be the first of the dry reactions, and consists in heating a little of the dry powdered substance in a small bulb tube.

How to Make a Bulb Tube.

A piece of soft glass tubing, about 5in. or 6in. long and ¼in. in diameter, should be chosen, and held in the Bunsen flame till the middle of the tube is quite soft, when the two ends are drawn apart, thus obtaining a shape such as shown at *a*, Fig. 1. The tube is cut into two pieces at the drawn-out portion, and each is made into a bulb tube by heating the end uniformly so as to obtain the shape shown at *b*, and then by blowing gently into the open end while the other is still hot we obtain the bulb tube, *c*.

Reactions Observed: Change of Colour, Sublimation, etc.

Many changes may be observed by heating substances in the bulb tube, such as change of colour without decomposition (as in ZnO, Fe_2O_3, PbO, etc.), sublimation (Am, As, Hg, Sb, etc.), and evolution of gas (HgO, carbonates, nitrates, etc.).

After the reaction by heating the substance alone in the closed tube has been observed, a little of the substance should be mixed with dry carbonate of soda and again heated, when, if mercury or arsenic is present, a black shining mirror will be obtained in the cool part of the tube.

Experiment 1.—Heat a little of the red oxide of mercury in a bulb tube, as shown in Fig. 2. Notice, first, the change of colour; second, the black shining mirror of metallic mercury, which by rubbing with a match may be run into a globule of metal; and third, the evolution of oxygen gas, which may be proved by a glowing splinter bursting into flame on being introduced into the mouth of the tube.

Experiment 2.—Introduce a little oxide of arsenic into a small bulb tube and apply a gentle heat. Notice the sublimate of white octahedral crystals formed in the cool part of the tube.

In the Open Tube.

This is simply a straight piece of tubing about 5in. long, and about ¼in. in diameter. The powdered substance is placed about ¾in. from one end of the tube, which is inclined during heating so as to admit of the free passage of air up the tube.

Reactions Observed: Evolution of Gas, etc.

The principal reaction to be noticed in the open tube is the evolution of sulphur dioxide given off by the oxidation of the different sulphides. We also obtain sublimates in the open tube similar to those obtained in the closed, but where a difference is observed it is due to oxidation during sublimation.

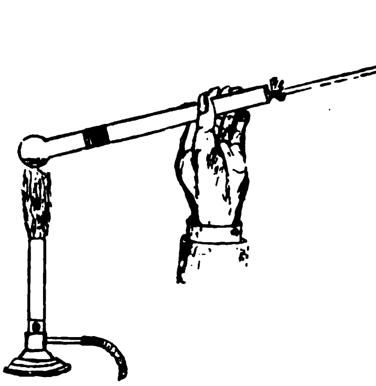

Fig. 2.

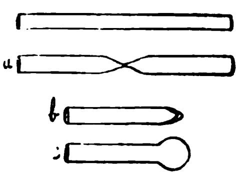

Fig. 1.

Experiment 3.—Heat a little sulphide of antimony in the open tube, and notice, first, the smell of the sulphur dioxide, and, second, that the sublimate, which consists of antimonious and antimonic oxides, is a white one, near to the substance.

Charcoal Test.

This is a very important test, and consists in heating a small portion of the substance on charcoal in the blow-pipe flame. The charcoal should not crackle on heating, and must be free from cracks, otherwise the melted beads of metal would disappear down the cavities.

The Blow-pipe and Blow-pipe Jet.

An ordinary common blow-pipe, *a*, is shown in Fig. 3, and

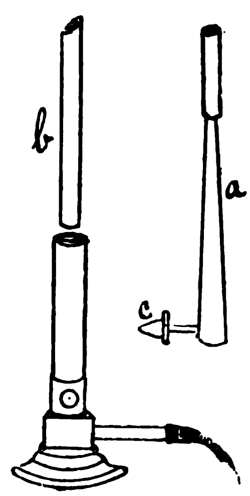

Fig. 3.

will serve all the purposes of the student, though other more elaborate looking pieces of apparatus, with platinum nozzles, may be obtained. The hole in the nozzle, *c*, should be perfectly round, and about the diameter of a pin, so as to get the best effect on blowing. The blow-pipe jet, *b*, with an inclined flattened orifice, *d*, is inserted in the barrel of a Bunsen burner, and the holes for the admission of air into the latter are meanwhile closed to prevent the gas taking fire at the bottom. The stream of air is directed down the incline, *d*, and a constant blast is maintained by keeping the cheeks inflated, and using them as a reservoir for the gradual passage of the air from the lungs to the blow-pipe, while respiration is continued through the nose.

Blow-pipe Flame: Oxidation and Reduction.

There are two parts to the blow-pipe flame, known as the reducing and oxidising flames. The former is shown at *b*,

Fig. 4, and is best obtained by just resting the tip of the blow-pipe nozzle, *c*, on the incline, *d*, of the jet, and blowing gently along the slope, while the oxidising flame, *a*, which is really beyond the visible portion, is most successfully produced by allowing the nozzle, *c*, to rest half-way down the incline, *d*, as shown, using a good strong blast. The luminous jet should be adjusted to a height of about 1½in. before commencing to blow.

Results Observed: Incrustations, Metallic Beads, etc.

A. *In Oxidising Flame.*—A small hollow for receiving a small portion of the powdered substance is made in a piece of well-scraped charcoal free from cavities, and the oxidising flame is directed on to the powder gently so as not to blow the latter away. If deflagration occurs, it indicates that nitrates or chlorates are present, but if we obtain an incrustation on the charcoal round the hole we may infer arsenic, antimony, etc. If a white incrustation is formed, or if the substance remains white, we may add a drop or two of cobalt nitrate and heat again, a change in colour of the incrustation, or substance, indicating zinc (green), magnesium (pink), tin (blue-green), or alumina (blue). The alkaline earths when heated alone in the oxidising flame are highly luminous.

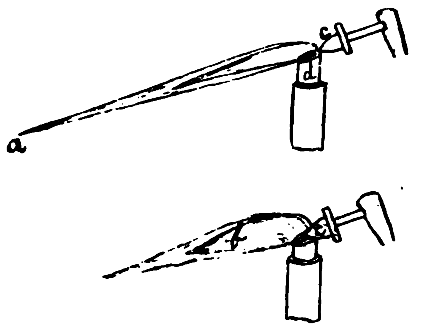

FIG. 4.

B. *In the Reducing Flame.*—The principal results to be looked for in heating a substance in the reducing flame are the beads of metal indicating lead, silver, bismuth, etc., and the changes in magnetic properties of the fused mass showing the presence of iron, nickel, or cobalt. In some cases the reduction will not take place with charcoal alone, and the powdered substance is therefore reheated after mixing with carbonate of soda or fusion mixture.

The latter is prepared by mixing sodium carbonate and potassic carbonate in the proportion of their molecular weights, about 10 parts of the former to 13 of the latter. This mixture fuses at a much lower temperature than either separately, forming the compound $KNaCO_3$.

When tin is being looked for, it will be found impossible to obtain a large bead of tin as the latter is so difficult to reduce, and in this case the substance should be heated with a mixture of sodium carbonate and potassium cyanide, afterwards crushing the fused mass in a mortar with water, and pouring off the soluble and floating matter, when the shining specks of metal may be seen with a lens at the bottom of the mortar.

Experiments 4 *and* 5.—Heat small portions of an arsenic and antimony salt in the oxidising flame, and notice that both give white incrustations, the latter being much nearer to the substance than the former, which also gives a strong garlic odour. Care should be taken not to use too much arsenic, as the poisonous effects are well known, and even small quantities are liable to produce headache.

Experiment 6.—Mix a small portion of a bismuth salt with sulphur and potassium iodide and heat gently in the oxidising flame, when a beautiful red incrustation characteristic of bismuth will make its appearance on the charcoal.

Experiment 7.—Heat a little of a zinc salt in the oxidising flame on charcoal, and to the white incrustation and substance add one or two drops of cobalt nitrate solution, afterwards reheating very strongly when a fine green mass will be obtained which indicates the presence of zinc.

Experiment 8.—Heat sulphide of lead or galena strongly on charcoal in the reducing flame till all the small beads of metal have run together into one large globule, and it will be found that the bead so obtained is malleable and marks paper.

Experiment 9.—With a salt of copper, such as nitrate of copper, mix about an equal bulk of carbonate of soda, and heat strongly on charcoal in the reducing flame for several minutes. If the experiment has been carried out successfully, a red mass of metallic copper will be obtained.

Experiment 10.—Heat a salt of iron similarly with carbonate of soda on charcoal in the reducing flame, and prove that the black residue thus remaining can be attracted by a magnet.

BORAX BEAD REACTIONS.

This will be found of great use in recognising some metals, as a few give very distinctive reactions when heated in the borax bead in the oxidising and reducing flames respectively.

Borax ($Na_2B_4O_7 10H_2O$), when heated loses its water of crystallisation and gives the anhydrous borate $Na_2O\begin{matrix}B_2O_3\\B_2O_3\end{matrix}$ and this, if brought in contact with an oxide, such as oxide of cobalt (CoO), combines with it, forming the blue double borate $Na_2OB_2O_3 + CoOB_2O_3$.

How to Make a Borax Bead.

A piece of clean platinum wire about 4in. long is taken, and a loop is made on the end not larger than this, O, by winding it round a pencil-point. The loop is then heated in the oxidising flame of the blow-pipe, and while the wire is still hot it is dipped in borax, what adheres being afterwards fused up to a clear bead. This should be shaken off whilst hot, as it will have absorbed any impurity which remained on the wire, and another bead is made in the same way by taking up borax and heating till the bead is of the proper size and quite clear.

Results Observed: Colour of Beads.

The substance to be tested is made to adhere by touching it with a hot borax bead, and by strongly heating in the oxidising and reducing flames respectively we may obtain significant colours, varying with the metals present, the colour sometimes altering during the change of the bead from hot to cold.

Experiment 11.—Make a borax bead as above described, and, after taking up a little cobalt nitrate, heat the bead strongly, first in the oxidising and then in the reducing flame. Observe the colour in each case, both hot and cold, and notice that the bead always remains of a dark blue colour, which is an unfailing test for the metal cobalt.

Experiment 12.—A good test as to whether the student can produce a good oxidising flame may be made by heating a little molybdic anhydride first in the reducing flame and afterwards in the oxidising flame. In the former case a brown bead appears, which on heating strongly in the oxidising flame, if the latter is a good one, becomes colourless.

Experiment 13.—A similar test may be made with the reducing flame by heating a little manganic oxide in it after obtaining the amethyst red bead in the oxidising flame. If a good steady reducing flame is obtained, the bead will become quite colourless.

(To be continued.)

A DESCRIPTION AND COMPARISON OF THE METHODS OF ELECTRIC LIGHTING AT PRESENT IN USE IN LONDON.*

BY ALEXANDER B. W. KENNEDY, F.R.S., M.I.C.E., ETC.

The vigorous and successful work done during the last two or three years by the various companies which are supplying electricity under Acts of Parliament has now brought the question of lighting our houses by electricity out from the region of hoping and scheming into that of practical—and already even financial—success. Nowhere has this been the case more than in London, where the whole of the metropolitan area has been parcelled out to various companies, generally two companies, having different systems

* Reprinted from the *Transactions* of the Royal Scottish Society of Arts, vol. xiii., part 1. Read May 11, 1891.

of distribution, to each area, most of which are now in active work. Not only to electricians, therefore, but still more specially to those who are still in the outer darkness which precedes the coming of electric light, the present condition of this matter in London may be specially interesting. This is, of course, the reason for my presence here this evening. It happens that I have myself designed some of the largest distributing systems and central stations in London—stations which, I am happy to say, are already in very successful operation—and therefore I may claim, at least, the advantage of a practical knowledge of the subject on which I have to speak to you. Perhaps I may say also, although this is a purely personal matter, that it gives me special pleasure to speak on this subject in a city of which I was so long a citizen, and with which I have so many pleasant associations as Edinburgh.

I will confess, at the outset, that I always feel a lecture of this kind to be a peculiarly difficult task. Nothing is easier than to talk technically to technical men, but I have been warned by your secretary that the members of the R.S.S.A. are by no means all technical men, and that I must not at all assume even an elementary acquaintance with electrical science on the part of all my hearers. At the same time, I cannot be far wrong in assuming that some of my audience have an intimate acquaintance with the theoretical part of the matter at least, if not with the special details of what may be called metropolitan electricity. Under these trying conditions I can only express a hope that those of my audience who are electricians, or engineers, or both, will bear with me while I am dealing with matters of great familiarity to them, and that those who look on the subject simply from the point of view of good citizens who would like to use electric light if they could get it, will pardon me if at times I am somewhat more technical than interesting or instructive to them.

To begin at the beginning. There are now at work in London a number of electrical companies, each in its own district, under its own special Act of Parliament, and each performing its duties in its own way, subject to the general control of the Board of Trade and the local authorities. The function of each of these supply companies is that simply of supplying electric current as the gas companies supply gas. They build central stations in which electric energy is generated, and lay mains along the streets, past the fronts of the houses, by which this energy is distributed to consumers. The mains are, of course, of copper, either in the form of insulated cable or of naked strip carried on insulators in conduits of some kind. Any person who wishes to use the electric light has his house wired for the purpose by one of the many contractors who undertake such work, and then has this internal wiring connected up to the company's mains, just as the internal gas-pipes of a house are connected with the street gas mains. The current used in the house is measured and paid for by meter, just as gas is, and the accuracy of the electricity meter—if not yet all that it ought to be—is at least probably greater than that of the ordinary domestic gas meter.

There are certain points about the generation of electricity in central stations which are common to all the systems in use in London and elsewhere, and which it may therefore be convenient to mention first. They lie at the root of the whole matter, and some understanding of them is at first essential for following the more detailed matters of which I have to speak later on. After what I have just said, I will not therefore further apologise for dealing with points at the outset which must be "household words" to some of my audience.

First let me remind you that the whole of the electric energy generated is obtained primarily by the combustion of coal. The electric energy is just as much a transformed form of heat energy as the mechanical energy used in workshops. Therefore, electric lighting, although it will avoid the blackening of walls and ceilings, is not to be regarded as a smoke preventer, as I have sometimes found to be popularly the case. In every central station for the generation of electric energy, coal is burnt in the usual way under boilers. In these boilers steam is generated, and is in its turn employed to drive steam engines, also in the usual way. The heat energy is thus, in the first instance, transformed into mechanical energy, electricity comes in in the next process only. The steam engine is used to drive a dynamo-electric machine, usually called shortly a "dynamo," and in this way a part of its mechanical energy is finally transformed into electrical energy. The dynamo may be looked at as the pump which pumps the electric current along the solid copper of the mains,* just as the pumping engine at water works pumps the water through the pipes

It is well that you should have some clear notion of what this most important piece of apparatus—the dynamo—is, and does. By far the best elementary illustration of the working of a dynamo machine which I have seen is one given last year in a lecture by Mr. Preece, and as you may not know it, I shall not hesitate to pass it on to you. It is a well-known fact in electricity that if a wire of conducting material, such as copper, be moved across the space between the poles of a magnet, what we call a current of electricity traverses that wire for the instant. A dynamo in its simplest form is a machine consisting of a very powerful electromagnet or magnets, between the poles of which a large cylinder of wires or bars, called an armature, is caused to revolve rapidly by a steam engine. Twice or oftener in every revolution, therefore, as a consequence of this forced motion of the conducting wires across the magnetic field, a current passes through each wire, and these currents, collected and directed by special apparatus, are the currents which traverse the mains and are utilised for lighting or for power, etc. The current in the mains thus consists of an accumulation or addition of an immense number of small currents, just as a river is the addition of an immense number of raindrops. As used for lighting, this river is again subdivided, just as an actual river would be if, near its mouth, the whole of its flowing water were taken away through endless channels for the purpose of irrigating land.

Mr. Preece's illustration was this: The earth is a huge, although feeble, magnet. Suppose a man stands anywhere between the north and south magnetic poles of the earth, facing one of them, takes in each hand one end of a piece of flexible copper wire, and proceeds to use the wire as a skipping-rope. As he skips, a current will be generated in the wire, and will pass through it and round through his body from hand to hand. The current will be excessively feeble, but could be measured by sufficiently delicate apparatus. The man in this illustration takes the place of a steam engine—he simply employs mechanical energy derived from the internal combustion of certain organic materials to swing his arms and drive the wire, which forms his armature. The magnet of this dynamo is, of course, the earth. The illustration is really both exact and striking. Substitute a powerful steam engine for the skipping citizen, a strong electromagnet for the earth, replace the single wire with a cylinder or a set of bobbins containing a very large number of wires, and increase the speed of skipping to 400, 600, or perhaps 1,000 revolutions a minute, and you have the ordinary dynamo of commerce, the sort of machine which is used—in endless modifications of course—in all central stations.

It is important that you should not think of the central stations generating electricity in the sense of creating it. The machinery only makes existing electricity available for doing work—it creates nothing. Into the most difficult question of the real nature of electricity, and its relation to the ether which fills space—if, indeed, itself be not this ether—it is obviously undesirable that I should enter to-night, even if the subject were one which I was competent to discuss. Without any pretence, therefore, to its being more than an approximate analogy, it may help you in following my further remarks if you think of things something in this way: Imagine a great pumping station for the supply of water under pressure to houses, for any purposes. Let there be beside it a very large reservoir of water. Let there be a double set of mains laid along the street, one main carrying the water to the houses, the other being, in fact, a drain to receive all the waste water from the houses, but carrying it back to the reservoir, and not to waste, if one may be allowed to suggest such a thing. If we further suppose the reservoir to be at a

* I hope I may be pardoned for ignoring for an hour the more modern view of the matter.

somewhat lower level than the houses, it is obvious that it might be standing full of water, containing any number of million gallons stored up, and yet the householder would be unable by any possibility to get a drop through the pipes into his house. (This, by the way, represents the present condition of Edinburgh in respect to electricity, except that the pipes are not yet laid!)

Now, in the station beside the reservoir let us suppose a pumping engine to be placed, and connected with the mains. Let it be arranged so as to draw water from the reservoir and force it under pressure through the pipes. No water is created, nothing exists which did not exist before, but now each householder can get whatever water he wants, whether to fill a bath or to work a lift, by simply turning on a tap. The engine simply does the work of pumping into his house. The reservoir never gets empty—indeed, the quantity of water in it never changes, for I have supposed that all the water used finds its way back through the return main.

In like manner the whole space around us is a vast inexhaustible reservoir of electricity. The dynamo is merely a pump which forces it under pressure through certain definite channels. These channels are made double ("go" and "return), in order to ensure greater certainty of working, but theoretically we might run a single main only, and allow the current to return by earth, just as we might allow the waste water to soak into the earth and so find its way eventually back to its reservoir. There are practical drawbacks about an earth return in both cases!

Just as we measure the flow of water in pounds per hour and its pressure in feet of head, so we measure the current (or rate of flow) and its pressure, in suitable units, which we call amperes and volts respectively, the former being analogous to the flow of water, the latter to its head or pressure.

It must be borne in mind that whatever electrical pressure it may be most convenient to use in the mains, the actual pressure at the customers' lamps must be constant, and nearly everywhere is fixed at about 100 volts. A variation of as much as 4 per cent. upwards from this will increase the brilliancy of the lamps very much, but decrease their life, while a variation of 4 per cent. downwards would very seriously indeed diminish the light. As a matter of fact, therefore, all the supply companies do their best to keep the pressure at their customers' lamps as nearly as possible constant at 100 volts.

The companies supplying electrical energy in London may be roughly classified in two different ways—namely, (1) as using high or low pressure in their mains, and (2) as using alternating or continuous currents. With one exception the two divisions are conterminous.

The three high-tension companies at present working are the Metropolitan, the London, and the House-to-House. The first-named covers most of the residential district north of Oxford-street, and includes also Lincoln's-inn-fields and other parts of the region between Oxford-street and Fleet-street, and round Charing Cross. It has stations at Sardinia-street, Rathbone-place, and near Manchester-square, besides a low-tension station at Whitehall, and a new station in process of erection at Paddington. The London Electric Supply Corporation has one generating station only, at Deptford, about six miles from Charing Cross, but has also several distributing stations over its district, which covers an irregular and very widely-extended area, including some of the best parts of Central London. The House-to-House Company has a small residential district at West Brompton supplied from one station.

Among low-tension companies the largest is the Westminster Electric Supply Corporation, with which I am myself connected, and which has, for its area of supply, Westminster (including the Houses of Parliament), Pimlico, Belgravia (with Buckingham Palace), and Mayfair, marching with the Metropolitan Company along Oxford-street. It has three central stations—one in Westminster, one in Belgravia, and one in Mayfair. Its district fortunately includes offices, shops, hotels, clubs, and private residences as well. The Kensington and Knightsbridge Company have a district at South Kensington mainly residential, with two stations and a battery station. The St. James's and Pall Mall Company have the cream of the lighting in London—that region in St. James's which is familiarly known as "Club Land"—which they light from one station in the centre of it. They are about to build another station for the northern part of their district. The Electricity Supply Company (Strand district) has a station near Covent Garden. The Notting Hill Company has a district mainly residential; its station has been very recently opened. In St. Pancras the matter has been taken up by the Vestry itself, and its first station will soon be ready.

All the high-tension companies mentioned use alternating currents, and all the low-tension companies use continuous or direct currents. The Chelsea Company, however, which has a station near Sloane-square, distributes continuous currents at high pressure on a system which I shall describe later on.

It is, of course, impossible here to make any exhaustive comparison of the merits of the different systems adopted in London. I will say at once, also, that I am not one of those who think that any one system has all the merits to itself. Indeed, I think it is quite open to doubt whether, for instance, the system which is best adapted for St. James's is also best adapted for Brompton. It is certainly not necessarily so, and I know personally that the different systems employed have been adopted in each case after careful consideration of their special circumstances by those responsible for the scheme. Whether or not a particular system is best in a particular place is not a matter which can be decided off-hand by mere expression of opinion, and without regard to the special conditions involved. I shall endeavour to give you, as fairly as I can, a sketch of the *pros* and *cons.* of the principal points of difference between the systems adopted.

First, as to the main division which I have mentioned between the systems, that, namely, between distribution at high and low pressure, or tension, as it is more often called. The analogy of water may here again be made use of. If it be required to do a given amount of work by water power, it can be done either by the use of a large quantity of water at a small head, or of a small quantity with a very high head or pressure. As we may otherwise express it, a given amount of energy may be furnished by the aid of water, either by sending a large quantity of water through the mains at a low pressure, or a small quantity at a high pressure. The work done, or the effect in energy, depends on the product of quantity and pressure—*e.g.*, 100lb. of water per minute at a head of 10ft. is equivalent to 1lb. per minute under a head of 1,000ft., although it is to be noted that a much smaller pipe would be necessary to convey the 1lb. than the 100lb. Exactly the same is true of electricity. One hundred amperes at a presure of 100 volts is the exact equivalent of 10 amperes at a pressure of 1,000 volts. The importance of this point is easily seen. When a current of electricity passes along the copper conductor or wire, which takes the place in this case of the hollow water main, a certain resistance is experienced analogous to the frictional resistance which accompanies the motion of water through a pipe. With a copper main of a given cross-sectional area this resistance increases—within certain limits—in direct proportion to the magnitude of the current—that is, double the current gives double the resistance, etc. Moreover, this resistance, like friction, is accompanied by the generation of heat; the copper conveying the current becomes hot, and a certain point is easily reached at which the heat so generated is sufficient to injure the insulating material round the metal. Whether or not, however, the heat should be unduly great, all the work done against the resistance is absolutely wasted, for useful purposes, exactly as is the similar work done in pumping water. Practically it is found by most low-tension companies that it is on these grounds inadvisable to allow copper mains to carry a current of more than 600 or 700 amperes per square inch of cross-section. As the output of a large station at full load is measured in thousands of amperes, this means that the trunk mains must have, in all, an area of several square inches, which is, of course, a very expensive matter.

On the other hand, the amount of current which a copper rod will carry is not affected by the pressure at which the

current is circulating. Hence there is an obvious *primâ facie* advantage in the use of a high pressure. It allows the quantity of current for any given amount of electrical energy to be reduced just in proportion as the pressure is increased, and as the former only affects the size of the mains, the use of high tension—other things being equal—allows the weight of copper in the mains to be reduced very materially. Moreover, by using a pressure so high that the loss of head in forcing the current through the mains is negligible, or at least is proportionately very small, the generating station can be placed at a considerable distance, several miles for example, from the district supplied. In itself this is, of course, not desirable—indeed, it is most undesirable—but naturally there may be places where the erection of a lighting station in the centre of a district which it has to supply is for certain sufficient reasons impossible.

I have said that the pressure of electricity in the customers' houses is a low pressure, and must be everywhere the same, whatever may be the pressure in the mains. Practically it is always about 100 volts. Hence clearly a distribution at high pressure would be impossible if there did not exist some ready means of changing the pressure from high to low at the customer's house. This requirement is met by the transformer or converter, which is at once the blessing and the trouble of the high-tension systems. To explain to you the nature of this apparatus, I am sorry to say that I have to leave my hydraulic analogy, which appears to furnish no parallel case. and must take the thing just as it stands.

It is necessary before doing this to look for a moment at the other division between the London companies—namely, the use of continuous and alternating currents—pointing out at the outset that so far as house-lighting goes, there is no difference between them, but that as yet motors have practically only been driven by continuous currents. If you recollect my description of the way in which current is produced by a dynamo, you will see that that current really cannot be completely continuous. It consists of a series of very rapidly-occurring successive flows of current. For all practical purposes, however, this current may be treated as continuous, for by a piece of apparatus called a commutator, which forms part of the dynamo, all the currents are made to flow in the same direction. A really continuous current is only furnished by a battery, but so far as all its leading characteristics and its measurement go, the current from a continuous-current dynamo is identical with that furnished by a battery.

Such a current, as we shall see directly, cannot be transformed in pressure in the way I have alluded to. It is quite possible, however, to arrange a dynamo—which then requires no commutator—so that it delivers its current, not continuously, but in what may be called wavelets, swinging first forward, then back. An electric current of this kind is called an alternating current, and is used by all the high-tension companies which I have mentioned in London. Each wave of current is complete in itself, and occupies generally from one-eightieth to one-hundredth of a second, forming a complete cycle of what—in default of a better expression—we may call a go and return current, and between each pair of waves the current is zero—that is, the flow ceases absolutely, although for an infinitesimally short time.

(To be continued.)

MODERN APPLICATIONS OF ELECTRICITY TO METALLURGY.*

BY G. C. V. HOLMES, SEC.I.N.A.

(Concluded from page 137).

Applications of the Elmore Process to Manufactures.—It might probably at first be thought that in consequence of the copper being deposited on a mandrel in the form of a tube this process was very limited in its application, and that few kinds of articles could be manufactured by it. This is, however, not the case. Such goods as steam-pipes, calico printers' and other rollers, the coatings of hydraulic ram-plungers and, in fact, anything of a plain circular section can, of course, easily be made, but so also can sheet copper, tape for electric lighting, pots and pans of circular section and with flat or curved bottoms, cartridge cases for heavy and quick-firing guns; also high-conductivity wire can be produced by simply cutting and drawing without melting the deposited metal.

If a tube be cut open in the direction of its length and flattened out, a single sheet is produced, the size of the sheet being dependent solely on the diameter and length of the mandrel. It would, however, be a tedious operation to remove a large mandrel from the tanks and remove the tube from it every time it was required to make a sheet. The Messrs. Elmore have got over this difficulty in the most ingenious way by taking advantage of the severance of continuity in the metal that results from oxidising the surface, either by interrupting or reversing the current. In this way they can form a tube, the walls of which, to all appearance, are perfectly solid, but which in reality are laminated throughout. The thickness of the separate layers or laminations can be regulated to a nicety, and when the built-up tube is withdrawn from its mandrel and cut open it separates up into its constituent layers, so that instead of one sheet several can be obtained.

Tape for electric lighting can be produced by cutting up a simple or a laminated tube spirally in a lathe or in a special cutting machine and unwinding the spiral. You can thus produce, without rolling or heating, a strip of rectangular section and of perfectly pure copper. This is a product which will be highly valued by electric lighting engineers, for even a minute percentage of copper oxide in the metal considerably reduces the conductivity of the material.

Wire for electric purposes is made by depositing a tube as usual and cutting it into a spiral as before, but of square section. The strip thus formed is drawn through dies in the usual manner. This process for making wire compares most favourably with the older method, to which reference was made in the earlier portion of the paper. The copper being absolutely pure is of very high conductivity, and always perfectly uniform. It possesses also the advantage that it can be drawn through a great number of holes without being re-annealed.

Results of Experiments with Copper produced by the Elmore Process.—Messrs. Clark Forde and Taylor have carried out experiments on the qualities of wire made under this process, which have given most interesting and important results. The conductivity of the hardest Elmore wire having a breaking strain of 29 tons per square inch was found to be about 2½ per cent. higher than that of soft annealed wire of the best quality hitherto procured commercially, and the annealed Elmore wire has a conducting power 4½ per cent. above that of the best commercial copper. The hardness of the wire tested was so great that the elongation under the strain at the rate of 29 tons per square inch was only ¾ per cent.

The tensile strength, elastic limit, and extensions under strain of Elmore tubes may best be illustrated by reference to the accompanying table of results obtained by Prof. W. C. Unwin, F.R.S., and Prof. A. B. W. Kennedy, F.R.S. They show many interesting features. The tensile strength is proved to be equal to that of mild steel instead of that hitherto accepted for commercial sheet copper, which latter is usually about 14 tons per square inch. In one instance the tensile strength of the Elmore sheet reached the extraordinary limit of 42·28 tons per square inch. The widely diverging results are not due to accident, but can be reproduced at will to suit varying requirements by altering the conditions of deposition. Another most important point brought out by the experiments is the very high ratio of elastic limit to breaking load. This ratio is perfectly under the control of the manufacturer. In some instances it came out as high as 0·92, which means that the material might be loaded up to 92 per cent. of its ultimate breaking strain and yet return to its original dimensions. This quality in engineering structures is of course of great importance. Equally satisfactory are the figures showing the percentages of extension and reduction of area of fracture. These prove the extreme ductility and uniformity of the material even when worked cold.

The test marked "annealed," third from the bottom of the list, is worthy of particular attention. The process of heating and annealing had reduced the tensile strength of the material to 14·78 tons per square inch, which is about the strength of good commercial sheet unannealed, but the extension on the length of 3in. was no less than 62·3 per cent. This reduction of strength, due to heating, is inherent in all coppers, no matter what the process of manufacture may be, but it is worthy of remark that it is quite unnecessary to heat the copper deposited under the burnisher for the purpose of working it, for even such difficult operations as flanging a pipe can be carried out with ease successfully in the cold state. The numerous samples exhibited, all of which have been worked cold, prove this; but perhaps a still more convincing proof is furnished by the record of an extraordinary experiment carried out by the well-known French firm of coppersmiths, Messrs. Guéldry,

* Paper read before the Junior Engineering Society, Jan. 15.

TABLE II.—Table showing the Results of Tensile Tests, carried out some by Prof. W. C. Unwin, F.R.S., and some by Prof. A. B. W. Kennedy, F.R.S., made on Pieces of Copper cut from Tubes deposited by the Elmore Process.

Breadth of sample, inches.	Thickness, inches.	Area, square inches.	Limit of elasticity Tons per square inch.	Breaking load. Tons per square inch.	Ratio of limit of elasticity to breaking load.	Length on which extension was measured, inches.	Extension per cent.	Reduction of area at fracture, per cent.

Grimault, et Tillier, of 66, rue Amelot, Paris. They reported, 9th December, 1891:

"We have tried and tested in every way the last copper tubes of 52·48 millimetres, which you sent to us on the 3rd inst. Without annealing we have been able, by drawing out the tube on a mandrel, to reduce the thickness from two millimetres to $\frac{6}{10}$ths of a millimetre, and the outside diameter from 52 millimetres to six millimetres, and we could have drawn it still further down. Without annealing we have been able, by drawing out the tube without a mandrel, to reduce the diameter from 52 millimetres down to 14 millimetres, bringing the thickness from two millimetres up to three millimetres. All these manipulations have not in the least injured the metal, which remained equally malleable and rigid—a result simply marvellous. Our conclusion is that you can now produce perfect tubes, and of a quality hitherto unknown."

The writer has dwelt at great length on the physical qualities of copper deposited under the system of continuous burnishing, because it is by these qualities that the material must stand or fall.

Cost of Manufacture by the Elmore Process.—The remarks which have been previously made on the cost of electro-refining copper apply equally to the Elmore process. The mere cost of deposition must be the same in both cases, such elements as cost of labour, fuel, etc., being the same—provided that the difference of potential between the terminals of each tank and the quantity of the current remain the same.

Owing to the arrangements of anode and cathode not being so favourable as in the refining process the resistance of the tanks must be somewhat more, and this cause, coupled with the greater current density used in the burnishing process, makes it necessary to work with a higher difference of potential per tank. The actual difference varies according to the size and number of mandrels in each tank and the arrangement of the anodes. In practice, it may on the average be taken as two-thirds of a volt, at which figure, as already seen, a ton of copper can be deposited for each ton of coal burnt in the furnaces of the boilers which supply the dynamo engines. The extra cost of plant required for the burnishing process must be taken into account, though this is partly neutralised by the increased current density which can be used. The cost of cyaniding, of adjusting the mandrels in the bath and removing the tubes from the latter, must all be considered; but the author is informed that, when every item of increased expenditure has been taken into account, the whole cost of manufacture on an output of from 20 to 30 tons per week comes to about ½d. per pound weight of manufactured article. This result is certainly satisfactory.

The subject for this paper has been chosen by the author partly because it is one of comparative novelty, and partly because he believes that electro-metallurgy is destined to be an important factor in our national industry, and that it will consequently afford a profitable field of employment for the engineers of the rising generation. We are now only on the fringe of the subject. Copper has yielded first to the efforts of the electrician because it happens to stand at the very bottom of the list of commercial metals given in Table I. (*vide E.E.* Jan. 22), but the others will follow sooner or later, though their treatment will not be quite so easy. Already results have been heard of and even specimens seen which are of the brightest augury for the future, and for this reason the author has not hesitated to present an elementary and necessarily imperfect account of recent improvements in the electro-metallurgy of copper.

GLASGOW TRAMWAYS.

COMPARATIVE STATEMENTS OF COST OF TRACTION BY VARIOUS SYSTEMS OF HAULAGE.

First.—ANIMAL TRACTION.—For the year ending 1890 traction on the Glasgow tramways, including maintenance and renewal of the plant therewith connected, in so far as that can be ascertained from the published accounts, cost 6·031 pence per car mile.

Second.—ELECTRIC TRACTION BY ACCUMULATORS.—The cost of working, based on offers received, and adding thereto the further charges necessary to cover outlays corresponding to these embraced in the cost of animal traction, and also interest at 5 per cent. on the excess of capital required for working by accumulators as compared with animal haulage, amounts to 4·951 pence per car mile.

Third.—CABLE POWER TRACTION.—The cost of working, based on offers received, and adding thereto the further charges and interest as before stated, amounts to 5·053 pence per car mile.

It would thus appear that mechanical power by electric accumulators is fully a penny per car mile run less than animal traction, and by cable haulage, on an extended system, a saving of rather under a penny per car mile run.

Mechanical haulage should be less liable to increased cost from such incidents as are liable to affect animal haulage. For example, provender for the horses on the Glasgow tramways has cost for the half-year ending December 31, 1891, fully 21 per cent. more than in the half-year ending December 31, 1890, and it is the cost for the year 1890 on which the foregoing figures have been prepared. The increased cost per car mile for provender alone will be about one-third of a penny per car mile run.

Of course the cost for animal haulage in Glasgow is an ascertained fact. The cost of mechanical haulage, as before given, although mainly based on offers received, has nevertheless some items, such as maintenance of track, etc., which can be actually ascertained only when such systems of haulage have been in use for some time, but the margin of about a penny per car mile in favour of mechanical haulage should be an ample allowance for such contingencies.

The receipts on tramways worked by mechanical haulage are as a rule greater per car mile than on cars worked by animal power.

PORTSMOUTH.

According to our advices the question of electric lighting at Portsmouth has not been settled without some squabbling. We do not approve of the procedure, but refrain from criticism, being content to give the position of affairs as it seems to stand at the present time. At the last meeting of the Council the Electric Lighting Committee again brought up their report, recommending that the portion of the resolution previously passed by the Council adopting Mr Shoolbred's scheme for the electric lighting of the borough be rescinded; submitting Prof. Garnett's report, and recommending its adoption; and recommending, further, that the committee be authorised to acquire a sufficient site for the central station.

Alderman Ellis, in moving the adoption of the first recommendation, said Mr. Shoolbred's estimate in respect of the private lighting scheme was that each lamp would earn £1. 6s. per annum, whereas it came to the committee's knowledge that the average earnings of a lamp were only £1. They invited Mr. Shoolbred down to prove his estimate, but the only English town he cited in support of this figure of £1. 6s. was Bradford. The speaker then went to Southampton, where the nearest electric lighting station was in existence, and found that the average earnings per lamp there were only 18s. To adopt Mr. Shoolbred's scheme, under the circumstances, would probably have meant a loss of thousands of pounds of the ratepayers' money per annum. Under these circumstances the committee felt it was only the right thing to do to come before the Council, admit their mistake, and make the present recommendation that the resolution adopting Mr. Shoolbred's scheme be rescinded. Prof. Garnett's report did not come in for many days after this decision had been arrived at in committee.

Mr. Dittman seconded the resolution.

Alderman Ellis next moved the second clause, recommending that the scheme and report of Prof. Garnett should be adopted, that he be appointed as consulting engineer, and that Messrs. Waller and Manville be appointed superintendent engineers, the fees for both together being £1,500. He said they were

not proposing any new-fangled notion which had not been tried in other towns, but one which would, when the whole of their lights were going, give a profit of £3,000 per year. He further said that all the practical men to whom he had mentioned the utilisation of the tide in producing power for electricity had laughed at the idea.

Mr. H. P. Foster seconded the clause.

Sir W. Pink disclaimed having any antagonism to the scheme or to any desire for postponing the matter, but he moved as an amendment the resolution of which he had given notice, and which was as follows : "That it be an instruction to the Electric Lighting Committee to consider and obtain information as to the possibility of utilising tidal power for the lighting of those parts of the borough contemplated in the provisional order, and to report to the Council." He supported his view by reading a letter from Colonel Crease, who pointed out the value of the power of the tide at Langstone Harbour. Another letter which he read was from Sir F. Bramwell, who held a similar view, and suggested that a bridge between Hayling and Southsea might be included in the scheme. He knew that the electrical papers had "pooh-poohed" Prof. Garnett's report as to electricity for Portsmouth, but with that he had nothing then to do, though if by a few weeks' postponement they could only get a constant power with only a first expenditure it would be worth consideration.

Mr. Miller seconded the amendment, and deprecated the adding of another burden to their present debt for that which would be a luxury only.

After a long and acrimonious discussion, the amendment was lost by the casting vote of the Mayor, and the resolution carried by 21 to 17 votes.

LYNN.

A lecture on "Electric Lighting" was given the other evening before the members of the Lynn Students' Association by Mr. E. J. Silcock, C.E.

Mr. Silcock, in the course of a long and carefully-prepared lecture, dealt with the ancient mode of lighting by torches, oil lamps, and gas, which, he said, were immense strides towards a perfect system, though he hoped to convince them that electric lighting was far in advance of either, more especially from a health point of view. Although only of very recent growth, it had come to a very high state of excellence, and was now long past the experimental stage. This result was due to the fact that there were and had been many workers in the field, amongst them men with the keenest scientific intellects and the best scientific training of the day. No satisfactory answer could be given to the enquiry, "What is electricity?" though there was perhaps no phenomenon of nature which had been more closely studied, or whose effects could be more accurately measured and foretold than electricity. It could be conveyed from one point to another by means of conductors, and was produced by friction, chemical combustion, and by induction. Having explained the technical terms used in electrical matters, he went on to describe the various machines by means of diagrams, following with information as to the working of incandescent and arc lamps. Storage of electricity was also dealt with, and as to the cost he said that it was a mistaken idea to suppose it was very expensive, and therefore only the light of the rich. The cost was very little in excess of gas, and if all circumstances were taken into consideration it was much cheaper. One pound of coal placed in a retort and distilled would produce about five cubic feet of gas, which would produce with the best appliances a light of 16 candles for an hour. If the same coal was placed in a boiler and used to make steam to drive an engine and dynamo, it would, in an incandescent lamp, give three times the light, and in an arc lamp 18 times as much. Electric lights were so easily lighted that a great saving was effected by those who used it, because they only turned the light on just when they wanted it, whereas the trouble of lighting gas and putting it out prevented it being so economically used. A saving was also effected, because furniture, etc., was not deteriorated as with gas. When health was considered, electric lighting was a long way ahead of all other means of lighting. Gas, candles, petroleum, etc., contaminated the air, and loaded it with carbonic gas, sulphuric, and other injurious gases. The latter part of the lecture was illustrated by diagrams giving the oxygen consumed, carbonic acid produced, the air vitiated, and the heat produced by the combustion of certain bodies burned so as to give the light of 12 standard candles for one hour. He concluded by expressing the hope that it would not be many years before there was a public supply of electric light in Lynn, by means of which any householder who desired it might be supplied.

COMPANIES' MEETINGS.

LIVERPOOL OVERHEAD RAILWAY COMPANY.

The half-yearly meeting of this Company was held on Tuesday at Liverpool. Sir William Forwood presided.

The **Chairman**, in moving the adoption of the report, said they had spent during the past half-year in the construction of the railway £103,515, which made a total expenditure up to date of £357,361. The construction of the railway had made rapid progress; the line was completed more than half-way; the foundations were completed right over the whole length; and nearly all the columns had been fixed. The Directors had lately visited the Electric Construction Corporation's works at Wolverhampton and inspected the electric plant, and they were satisfied that when brought into play it would work effectually. They expected that the railway would be completed and open for traffic during the autumn.

Mr. Richard Hobson seconded the motion, which was carried.

A special meeting was held subsequently to consider a proposal to raise £75,000 by the issue of debenture stock to that amount.

The **Chairman** said the resolution was a formal one, and it was agreed to *nem. con.*

A further special meeting was held to decide as to the promotion of a Bill in Parliament "to extend the time for the construction of certain authorised railways, and to authorise the Liverpool Overhead Railway Company to make certain extension railways, and for other purposes."

The **Chairman** said that as they were going to Parliament for an extension of time, they thought it well to ask for powers to include two other projects, one to extend the south end of the line some 800 yards, so as to bring it into connection with the Cheshire Lines system, and another at the north end, 200 yards in length, as far as the Crosby-road and close to the Lancashire and Yorkshire line; thus placing the overhead railway in direct touch with Manchester, East Lancashire, and Yorkshire, as well as important suburban and residential districts, greatly to the convenience of manufacturers and others.

The resolution was adopted.

CUBA SUBMARINE TELEGRAPH COMPANY.

The forty-first ordinary general meeting of this Company was held on Wednesday at the Company's offices, 58, Old Broad-street, E.C., Mr. Thomas Greenwood presiding.

The **Chairman** said that the accounts very much resembled those that were presented 12 months ago, the difference on either side being very small. Their income had been £380 more than that of the corresponding period last year, while they had saved about £50 in working expenses, which gave them £370 to the good, comparing one half-year with the other. They had taken from the balance £170. These sums together enabled them to put to the reserve fund £5,000, as against £4,450 in the corresponding period of the previous year. Nothing had been spent on repairs, as there had been no interruption of their cables. The average amount spent on repairs each half-year would amount to £3,000, a sum which, though it did not figure in the present, would in some future accounts. He concluded by moving the adoption of the report and accounts.

This was seconded by **Mr. Alexander F. Low**, and carried.

Dividends at the rate of 10 per cent. per annum on the preference and 8 per cent. on the ordinary shares were afterwards declared.

COMPANIES' REPORTS.

BIRMINGHAM ELECTRIC SUPPLY COMPANY.

The following report of the Directors will be submitted to the shareholders at the forthcoming ordinary general meeting of the Company :

Your Directors have pleasure in presenting their report and balance-sheet for the past nine months. It will be in your recollection that the accounts presented at the first annual meeting were made up to March 31 last. The alteration of the date of closing the financial year has been adopted to accord with the requirements of the Board of Trade. The accounts submitted herewith show a profit of £713. 16s. 4d., and, taking into consideration the fact that these accounts include the supply during the six summer months, the result cannot but be deemed satisfactory. Of this sum the Directors have applied £351. 16s. 7d. to depreciation reserve account, and recommend that the balance be carried forward to next year's account. The capital expenditure on buildings, plant, and mains during the nine months amounts to £7,761. 16s. 7d., this sum including a battery of accumulators and a fourth engine and dynamo. The demand for the light has been most satisfactory—the total number of 16-c.p. lamps, or the equivalent, on order at the 31st December being 5,480, which has since been increased by additions to 6,100. It will be of interest to note the company have now on their books as customers two hotels, five clubs, four public buildings, two institutions, 11 restaurants, 60 shops, two banks, eight insurance offices, 56 general offices. From the very ready way in which the light has been taken up the Directors fully anticipate a large increase in the output of the station, and in contemplation of this they propose putting down further plant to meet such demand. It is also intended to extend the mains through a portion of the areas allotted to the Company last year. There still remain of the Company's capital 5,625 shares unallotted, and the Directors consider that the time has arrived when it will be an advantage to the Company that these shares should be taken up. These will at once be offered to the shareholders, and afterwards to the public, at the discretion of the Directors. Two Directors, Mr. J. F. Albright and Mr. G. H. Johnstone, retire, and, being eligible, offer themselves for re-election. The auditors, Messrs. Sharp, Parsons, and Co., retire, and, being eligible, offer themselves for re-election.

NEW COMPANIES REGISTERED.

Tavernier's French Patents, Limited.—Registered by Williams and Neville, 23, Austinfriars, E.C., with a capital of £1,200 in £1 shares. Object: to acquire from A. E. Tavernier an electrical apparatus for the automatic indication of fire and the rise of temperature in the bearings of machinery, and the patent rights belonging thereto, and to develop and turn to account the same, in accordance with an agreement, particulars of which are not given.

BUSINESS NOTES.

Great Northern Telegraph Company. — The receipts for January were £20,000.

The Northern Electric Wire Company, of Halifax, have been able to again declare their usual dividend of 7½ per cent. per annum and carry forward a credit balance to next year's working.

Dividend.—The Telegraph Construction and Maintenance Company propose a dividend of 15 per cent. (£1. 16s. per share) in addition to the 5 per cent. already paid, making 20 per cent. for the year 1891.

City and South London Railway.—The poll demanded by Mr. Middleton at the meeting of this Company last week, on the question of the approval of the Islington Extension Bill, was taken at the Company's offices on Tuesday last. The result was a large majority in favour of proceeding with the Bill. The receipts for the week ending 7th February were £824, against £702 for the corresponding period of last year, showing an increase of £122. The receipts for last week showed an increase over those for the week ending January 31st of £1.

PROVISIONAL PATENTS, 1892.

February 1.

1876. **Improvements in alternating-current electromotors.** Rankin Kennedy, Carntyne Electric Works, Shettleston, Glasgow.

1878. **Improvements in means or apparatus for protecting underground electrical conductors.** Frederick Davis and Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

1880. **Improvements in electrical sound-producing apparatus.** Arnold Beaumont Woakes, 78, Harley-street, London.

1883. **Improvements in electrical telephone transmitters** William Lucas and Thomas Alexander Garrett, 53, Thornhill-square, Barnsbury, London.

1906. **Improvements in shades for electric lamps.** John George Byworth, 323, High Holborn, London.

1908. **An improved form of automatic accumulator, charging switch, and safety cut-out.** Thomas Barnet Grant, 15, George-street, Mansion House, London.

1924. **An electric switch.** George Sylvester Grimston, 28, Southampton-buildings, London.

1927. **An improvement in secondary voltaic batteries.** William Joseph Starkey Barber-Starkey, 28, Southampton-buildings, London.

February 2.

2008. **Improvements in electric light decorations.** Edmund Rathbone, 4, Clayton-square, Liverpool.

2012. **Improvements in synchronous electrical signalling apparatus.** George William Hart, 11, Furnival-street, Holborn, London.

2016. **An improved block for use in forming conduits for electrical or other cables or wires and for analogous purposes.** John Price, jun., 17, Southampton-buildings, London. (Complete specification.)

2017. **A new or improved method of and means for making zinc rods for electric bells and batteries.** George Turner, 46, Richmond-road, Dalston, London.

2020. **Improvements relating to electrical signalling on railways.** Charles William Catt, 6, Bream's-buildings, London.

2026. **Improvements in electric telephones.** Henry Harris Lake, 45, Southampton-buildings, London. (Elwood Aristides Grissinger and Theodore Grissinger, United States.) (Complete specification.)

2055. **Improvements in or relating to apparatus for closing electric circuits, for use in connection with position finders or the like.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (Giulio Bertolini, Italy.)

February 3.

2064. **Improvements in the construction of electro-pneumatic pressellos for electric bells and signals.** Walter David Parr, 167, Grunesthorpe-road, Sheffield.

2106. **Improvements in heating and welding by electricity.** Henry Howard, 24, Southampton-buildings, London.

2109. **Improvements in arrangements and apparatus for telegraph message signalling and other purposes.** Frederick *Thomas* Hollins, 10, Forest-drive East, Leytonstone Essex

February 4.

2163 **Improvements in electric measuring apparatus.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

2198. **Improvements in culverts for electric mains.** Fred Thornton and Latimer Clark, Muirhead, and Co., Limited, 24, Southampton-buildings, London.

February 5.

2225. **Improvements in the method of purifying electrolytes containing zinc, relating to or connected with the electro-metallurgic production of zinc.** Georg Nahnsen, 38, Alexander-strasse, Berlin. (Complete specification.)

2254. **Improvements in or connected with the holders of incandescent lamps.** William Phillips Thompson, 6, Lord-street, Liverpool. (Max Fuss, Germany.) (Complete specification.)

2260. **Improvements relating to the heating of metals by electricity and to machines therefor.** Henry Harris Lake, 45, Southampton-buildings, London. (George Dexter Burton, Arthur Herbert Eddy, and George Sift Briggs, United States.)

2278. **Improvements in and relating to electroliers or pendants and standards for electric lamps.** Thomas Coombe Moore, 11, Southampton-buildings, London.

2283. **Improvements in systems of electric distribution.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, London. (Harry Ward Leonard, United States.)

2290. **Method or process of electric riveting.** Elias Elkan Ries 430, South broadway, Baltimore, Maryland, United States. (Complete specification.)

February 6.

2312. **Improvements in shade carriers for electric lamps.** Bernard Mervyn Drake, John Marshall Gorham, and James Saword, 66, Victoria-street, Westminster.

2329. **Improvements in process and apparatus for bleaching by electrolysis.** Oliver Imray, 28, Southampton-buildings, London. (Thomas James Montgomery, United States.) (Complete specification.)

2330. **Improvements in electric switches.** Edward Alfred Gimingham, 28, Southampton-buildings, London. (Complete specification.)

2336. **Improvements in dynamo-electric machines.** Hubert Doyer, 46, Lincoln's-inn-fields, London.

SPECIFICATIONS PUBLISHED.

NOTES.

Stuttgart.—The central electric station at Stuttgart is to be opened this week.

Coventry.—This Council have adjourned the question of electric lighting for six months.

Telephone in Russia.—Gatschina, the summer residence of the Czar, is now connected by telephone to St. Petersburg.

Harwich.—A motion not to proceed with the provisional order has been deferred pending negotiations with the gas company.

Arcas Plating, which we recently described, has been applied with success to electrical, philosophical, and mathematical instruments.

Mr. Tesla's Lecture.—Mr. Tesla is to repeat his lecture on vibratory currents before the French Française de Physique.

Elmore in Austria.—It is stated that water power is being taken in Hungary for the establishment of an Elmore copper-depositing plant.

Yarmouth.—The borough surveyor has been authorised to visit the Crystal Palace Exhibition to examine the systems of lighting there.

Southampten.—The Baths Committee have authority to appoint an engineer, at a salary of £1. 15s. per week, to attend to the boilers and electric plant.

Northampton.—At the commemoration ball to celebrate the opening of the extension of the Town Hall, the electric light was utilised for decorative purposes.

Leamington.—The town clerk has been instructed to inform the Aurora Electric Company that no consent to its application for a license should be given.

The Snowstorm.—A fall of snow, making itself more especially felt in the North, this week cut off Leeds from telegraphic communication with London and the Continent.

Flying Machine.—A flying machine, on the model of the flying fox, driven by a 3-h.p. electric motor, has been built by Messrs. J. Shaw and Son, of Coventry, for Major Moore.

London Telephones.—The London County Council have decided to enter petitions against the Bills of the National Telephone Company and the New Telephone Company.

Regent-street Mains.—The London County Council have approved the laying of Siemens's armoured cable in Beak-street and Carnaby-street by the St. James and Pall Mall Company.

Cheap Fares.—The Lambeth Vestry have decided to oppose the Waterloo and City Railway Bill if the promoters do not insert a clause providing cheap fares for the working classes.

Standard of Light.—Prof. Vivian B. Lewes, F.I.C., F.C.S., of the Royal Naval College, Greenwich, has been appointed secretary of the committee for investigating the standard of light.

Nottingham.—A deputation from the Nottingham Town Council visited the Crystal Palace on Tuesday, and were shown round the exhibition under the guidance of Mr. W. H. Preece, F.R.S.

Hucknall Huthwaite.—A resolution has been passed that unless the application for a provisional order for gas lighting were at once withdrawn, the Board would light the streets by other means than gas.

Liverpool.—At the meeting of the gas company on Tuesday, the chairman, Mr. E. Lawrence, said that, in spite of high prices and the competition of electricity, the consumption of gas was steadily increasing.

Cardiff.—A meeting of the Cardiff Electrical and Lighting Committee was held on Tuesday. The question of lighting Upper Grange and Saltmead was further considered, and the borough engineer was requested to report thereon.

St. Olave's.—The St. Olave's Board of Works have approved of the objection offered by the Board of Trade to the application of the Camberwell and Islington Electric Light and Power Supply Company for a provisional order in the district.

Antwerp.—The system to be adopted at Antwerp, proposed by M. Van Rysselberghe, consists in distributing water at high pressure with turbine and dynamo in each house; in fact, the Popp system again, with water instead of compressed air.

Institute of Secretaries.—An institute of secretaries has been formed to act as a central body in the same way as institutes for other professions. The first general meeting was held last month at Winchester House, Mr. E. C. Wickes presiding.

Hawick.—On Monday night the High-street of Hawick was lighted with the electric light. The Corporation will continue the experiment for three months, and if successful, will adopt the electric light instead of gas. The experiment will cost £100.

Taunton.—The Committee of the Town Council has received an amended offer from the electric lighting company as to the purchase of that undertaking, and a sub-committee has been formed to consider the same. The report thereon is expected in March.

The Telegraph in Mashonaland.— Telegraphic communication was on Wednesday finally established between Fort Salisbury and the Cape. The first message which was sent over the wire was a congratulatory telegram despatched to London.

Magnetic Lines of Force.—The monthly meeting of the Edinburgh Mathematical Society was held last Friday in the Edinburgh Institution. Prof. Steggall, who presided, read a "Note on a Laboratory Method of Finding Lines of Magnetic Force."

Canadian Telegraphs.—It is stated on high authority that the Hon. J. J. Abbott will introduce in Parliament during next session a measure for the placing of the entire telegraphic system throughout the Dominion of Canada under Government control.

Paper Shades.—Besides the catalogue of glassware we mentioned last week, we have received from Messrs. Paterson and Cooper a finely-printed catalogue of paper and silk shades for electric fittings which should be of great use to electrical contractors.

Steamer Struck by Lightning.—An unusual occurrence happened lately to the steamer "La Congo," which experienced a fearful passage on the Portuguese coast, and in the height of the storm was struck by lightning, several of the passengers and crew being injured.

Technical Education.—The National Association for the Promotion of Technical and Secondary Education, of 14, Dean's-yard, Westminster, issue an urgent appeal to the electors of the London County Council for the greater extension of technical education for London.

St. Petersburg.—The exhibition at St. Petersburg seems to be bringing on business. Several Austrian firms, besides many French firms, are exhibiting, and it is stated that Messrs. Ganz have already received an order from St. Petersburg for a large central station plant.

Edinburgh Tramways.—A special meeting of Edinburgh Street Tramways Company was held on Monday for the purpose of considering a proposed Bill in Parliament to authorise the company to work their tramways by cable or electrical power. The motion was unanimously carried.

Telephones.—Messrs. Woodhouse and Rawson send us their price-sheets of telephones, transmitters for domestic and long-distance telephony, embracing wall sets, inkstand sets, desk-shaped sets, military telephones, and cheap domestic sets of great convenience for private telephone installations.

Electric Advertising.—Mount Washington is to be capped by the largest search-light in the world by railway and hotel men as a curious advertisement to draw visitors. It reminds us of our little tale, which was so seriously and widely copied, about the search-light beacon on Mount Kilimanjaro.

London Telephone Service.— A special general meeting of the London Chamber of Commerce is to be held on Monday, at 2·30 p.m., for the purpose of discussing the general position of the commercial community with regard to the telephone service of London, and the telephone Bills now before Parliament.

Wiring Houses in the City.—The City of London Electric Lighting Company have issued a circular embodying the general conditions to be complied with in wiring houses for the electric light. Pressure on our space prevents us doing more than refer to it this week. Copies can be obtained at the office of the company.

Hanley.—At the Hanley Town Council meeting, on Tuesday, on the proposition of the Electric Lighting Sub-Committee, it was resolved to advertise for specifications and estimates of the cost of plant and distributing mains and machinery for lighting by electricity the area contained in the second schedule of the Hanley provisional order.

Gigantic Electrical Trust.—A Dalziel's telegram from New York says that an electrical trust has been formed by the consolidation of the Edison Company with the Thomson-Houston Company. The capital of the trust is to be 50 million dollars, and the president will be Mr. H. M. Trembly. The new combination will be the only rival of the Westinghouse Company.

Sims-Edison Torpedo.—A large number of scientific men, with nearly all the naval and military attachés, witnessed the first public trial of the Sims-Edison torpedo at Portsmouth on Monday. Mr. Sims explained and worked the torpedo in person as on the previous private official trial. Further improvements are yet being made both in reducing the size of the weapon and of the cable.

Melbourne.—Separate tenders are invited by the Council of the City of Melbourne for the supply and delivery of (1) electric light plant; (2) cables and insulators. Tenders will be received until April 2nd, and must be addressed to the Right Worshipful the Mayor of Melbourne, Victoria, endorsed "Tender for ——" (as the case may be). Mr. John Clayton, town clerk, Town Hall, Melbourne.

Fleetwood.—The Lighting Committee of the Fleetwood Improvement Commissioners have resolved unanimously that the reports read upon the question of adopting the electric light in this district be received, and that the clerk be instructed to obtain from Messrs. J. E. H. Gordon and Co., Limited, further details with reference to the working arrangements of their installation, to be considered at a future meeting.

Kimberley Exhibition.—A meeting was held on Tuesday at the Society of Arts, when a paper on the proposed exhibition at Kimberley was read by Mr. Lewis Atkinson, the manager. Mr. Atkinson gave statistics and particulars of the progress of trade in Kimberley, with views of the town and country. The exhibition is well supported by the Cape Government, and the shipping companies will give cheap rates.

Parliamentary.—In the House of Commons on Tuesday, the Baker-street and Waterloo Railway, the Central London Railway, the City of London and South London Railway, the Great Northern and City Railway, the Hampstead, St. Pancras, and Charing Cross Railway, the London County Council (General Powers, Subways, Tramways) Bills, and other private measures were, on the motion of Mr. Caldwell, read a first time.

Pacific Cable.—Telegrams from Melbourne state that the New South Wales Government have agreed to grant a small subsidy for the proposed Pacific cable subject to a reduction in the tariff. The Victoria Government, however, is unwilling to grant a subsidy. The proposal is that the cable shall start from Gladstone, a little south of Rockhampton, in Queensland, go thence to Fiji, Samoa, and Honolulu, and finally touch at some point on the coast of North America.

Viator Resartus.—"On Saturday," a correspondent of the *Birmingham Daily Post* complains, "I travelled in one of the Bristol-road electric trams, and next morning found the backs of both legs of my trousers a bright red, evidently due to the action of acid or acid fumes. If you will kindly call attention to the matter, no doubt the cause will be enquired into." H'm! H'm! this gentleman now knows what Shakespeare meant when he spoke of "the imminent, deadly breech!"

Chicago.—Plans adopted for lighting the buildings and grounds of the World's Fair now provide for 138,218 electric lamps, of which 6,766 are to be arc lamps of 2,000 c.p. each, and 131,452 incandescent, 16 c.p. each. The electric lighting will cost something like 1,500,000dols., and will be 10 times as extensive as was employed at the Paris Exposition. The light and motive plant at the exposition, it is estimated, will require 26,000 h.p., of which 22,000 will be required for the electric plant.

The Madras Tramway.—In reply to the application of Messrs. Champion and Short, the local solicitors for Messrs. Hutchinson and Co., London, for the construction of a tramway in the Madras city, the Madras Government has directed that the order sanctioning the line be published, and that intimation be given that any objections or additions which anyone has to make thereto must be made by the 31st March. Orders in regard to the tramway proposal will then be definitely issued.

Transmission of Power.—An interesting instance of transmission of power for a paper mill has been recently started in Aachtthal, South Germany, for Herr Friedrich Kutter. The waterfall 1½ miles away is utilised by a Girard turbine. The motor, supplied by the Allgemeine Company, works at 800 volts, giving 80 h.p. at an efficiency of 79 per cent. Bare copper wires are used, with oil insulators. Another set of plant of 580 h.p. is also used, partly for lighting and partly for transmission of power for a number of purposes.

Fire.—We are sorry to record that the premises of the new and energetic firm, Messrs. Hodges and Todd, of 12, Verulam-street, Gray's-inn-road, were burst to the ground

yesterday morning. The firm have been quite busy with electrical fittings, especially ammeters and voltmeters, a considerable number of which were ready for delivery. The premises were insured, though not perhaps to the full amount. Immediate steps are being taken to carry on the work in other premises until rebuilding can be accomplished, and the work will be carried on as usual.

Arlecdon.—At the Arlecdon and Frizington Local Board the surveyor, in reference to electric lighting by water power, said he found the Millyeat stream would be insufficient in a dry season or hard frost. Recently an electrical engineer visited them from Leeds, and came to the conclusion that water power was not available. The matter dropped, but, perhaps, if it were suggested, a steam engine would do as well. Engineers other than electrical are not always wont to leave matters thus on occasions when water power is not available.

The Inventor of the Three-Phase Motor.—Mr. C. E. L. Brown, in a letter to the N.Y. *Electrical Engineer*, states his opinion that Tesla should be acknowledged as the true inventor of the three-phase motor as used at Frankfort, constructed by himself and Dobrowolsky. He draws attention to Mr. Tesla's patents for the three-phase current filed October 12, 1887, Nos. 381,968 and 382,280, and his further patent No. 390,414, filed April 23 of the following year, which conclusively show who was the true inventor of the three-phase current system.

Cable to the Azores.—A contract was signed at Lisbon on February 11th by the Portuguese Minister of Public Works and the representative of the Telegraph Construction and Maintenance Company for the laying of a cable between Lisbon and the islands of St. Michael, Fayal, Pico, St. George, and Tercira, in the Azores. The cable is to be completed in a year. In consideration of this contract it is expected that the telegraph company will be in an advantageous position to satisfy more adequately the requirements of the public between Europe and Brazil, and the United States of America.

Freight to Chicago Exhibition.—The British railways have undertaken to carry goods for British exhibitors at the Chicago Exhibition, to and from the port of shipment, at half rates. The American railways will charge their usual rates to Chicago, but will bring back the goods free at the close of the exhibition. Many of the principal steamship companies have reduced their rates considerably, and will take freight for the exhibition at 11s. per ton. Many of them have also consented to adopt a reduced passenger tariff for exhibitors and their employés, certified as such under the authority of the Royal Commission.

Explanations at the Crystal Palace.—Old Indian (meeting electrical friend): O.I.: "Ah! you are the very man I wanted to see. I wish you would tell me what electricity is, and all about it." E.F.: "Oh, certainly, with pleasure; but do you know anything of the subject?" O.I.: "Yes—a little." E.F.: "Well now, would you know a volt from an ampere if you saw one?" O.I.: "No—I think probably not." E.F.: "And if you found a kilowatt in an open 'field' would you know how to catch and use it?" O.I.: "I fear I shouldn't." E.F.: "Ah! I see. Well, if I should meet you here again another time I will tell you *some more*. Good-bye!"

Railway Parliamentary Committee.—It is proposed to appoint a joint committee of Lords and Commons to consider the numerous electric and cable railway schemes projected within the limits of the metropolis by Bills introduced this session. The duty of such a committee would be to report whether underground railways worked by electricity or cable traction are calculated to afford sufficient accommodation for the present and probable future traffic, whether any of the schemes propose satisfactory lines of route, upon what terms and conditions the subsoil should be appropriated, and whether any of the schemes should be proceeded with during the present session.

Lightning Conductors.—An interesting paper on the above subject was read by Mr. Alfred Hands, F.R.Met.Soc., at the meeting of the Society of Architects last week. He insisted on the necessity for periodically testing conductors, and said that he had no hesitation in saying that at least 70 per cent. of the conductors in England were in such an unsatisfactory condition that they afford only partial protection, and damage might occur to the buildings on which they are fixed, while a large number were so absolutely bad that they would give no protection whatever. He also dealt with the question of when and where not to connect metalwork in buildings with conductors.

Obituary.—The death of Major-General Ryrie Alexander, late of the Bombay service, occurred at his residence, "Redwal," Dartmouth, Devon, on the 10th inst. For several years past it may be mentioned that Major-General Alexander had taken an interest in electrical matters, also in developing inventions relating to improved brakes and starters, with a view to reduce as far as possible the strain upon tramway and omnibus horses. He was a shareholder in several companies connected with the electrical industry, and for the past three years acted as chairman of Shippey Brothers, Limited. He had been failing in health for the past six months, prior to which he was engaged in perfecting an electric boiler feed-regulator.

The Aurora Borealis.—One of the finest displays of the aurora borealis ever known in this latitude was observed in New York on Sunday evening. Telegrams from various points show that the phenomenon stretched over a great belt of territory from Iowa to the Atlantic. A peculiar effect was produced on the telegraph system, and for intervals of three or four minutes at a time the wires were so surcharged with atmospheric electricity that between New York and Albany it was even possible to send messages without the aid of the regular batteries. The current, however, was intermittent. The aurora seemed to occupy the whole of the northern heavens, and was beautifully marked, the colouring being clear and distinct.

Brighton.—An item that should interest Prof. Forbes and other adherents of the use of destructors theory, comes from Brighton this week, where a lengthy discussion took place at the Town Council on a report from the Works Committee recommending the erection of a refuse destructor on a site adjoining Hollingdean-road. Councillor Lowther moved that the consideration of the same be deferred in order that the report might be made more complete. Eventually, however, the report was adopted. At the same meeting, on the recommendation of the Lighting Committee, the Council ordered additional electric light mains and distributors to be laid down in Church-street and through the Pavilion grounds and North-street.

Taunton.—The question of the purchase of the central station by the Taunton Corporation is still exercising the minds of the members. At the Town Council meeting last week, the Joint Finance and General Purposes Committee presented a report in which they stated that they had received an amended offer from the electric lighting company, and have appointed a sub-committee to consider the same, and the committee hope to be in a position to report fully thereon at the March Council meeting. The

committee are unable to accept the offer of the gas company to purchase the gas works, and the tendency, therefore, seems for the Corporation to run the electric light themselves against the local gas company. This will be "bad for the Co."

Electric Light for Wool Warehouses.—Messrs. D. C. Apperly, Carson, and Co., woollen warehousemen, 5, Cripplegate-buildings, and 13, Fore-street, have decided, after inspecting various installations and systems of electric lighting, to instal their own plant, consisting of arc and incandescent lamps, to be run direct from a gas engine and dynamo placed in the basement. The arc lights which are found most suitable are of a small size, so as not to be too glaring, and they are arranged on pulleys in such a manner as to enable them to be raised or lowered to any required focus, so that the most delicate colour may be successfully examined. All the lights have their independent switches, in order that each one may be turned off and on at will, and for examining goods special reflectors are being erected. The installation is being carried out by Mr. A. Bergtheil for the Wenham Company.

Notation.—*L'Industrie Electrique*, M. Hospitalier's new electrical venture, comes in handsome form with a series of interesting and original papers. The use of alternators with condensers receives mathematical disquisition; the standard of E.M.F. is dealt with, theoretically and elucidatorily, with special reference to the standard cell of MM. Baille et Fery; an article on improvements in accumulator practice by M. Roux does for France what Mr. Niblett has been doing for England; M. Laffargue also writes on accumulators; and M. Hospitalier has an article on the Parsons steam turbine. The French scientific societies are also reported. M. Hospitalier brings forward his own particular pet—electrical units and symbols—very strongly in an elaborate table of eight columns, and innumerable formulæ in the advertisement pages. The French for theory and the English for practice—and so the world wags.

Manchester.—The Manchester Central railway station was experimentally lighted by electricity last Friday. For the passenger department 40 Brockie-Pell arc lamps are provided, arranged in series, and elevated upon poles at the approaches, and in the station itself, suspended by wires from the roof. The lamps take 11 amperes each, in a 500-volt circuit, of which there are four. The various offices and the bookstall are supplied with 200 incandescent Edison-Swan lamps, each of 16 c.p. Edison-Hopkinson dynamos are used, and these, with the engines, which are of over 100 h.p., are placed in Trafford-street, from which point the communication is by cable. The installation for the goods department is not completed, but it is to be supplied with 70 arc and 60 glow lamps, the electrical arrangements being similar. The improved appearance of the station was the subject of general comment.

Electric Heaters.—Electric heating is coming along surely, though slowly. The editorial hat was ironed in a very workmanlike fashion the other day by one of the General Electric Company's electric heaters, and some electrically-cooked pancakes were distributed at the same time to a number of electrical devotees, who did not mind tampering with their digestion in the middle of the afternoon. The pancake, however, was cooked beautifully brown, and came to maturity in five minutes by the watch. The current was taken from an ordinary flexible and wall plug from a lighting circuit, taking three amperes and 100 volts for this space of time, and cooking three pancakes in series. Many householders in the flats around Kensington and Westminster would be glad enough of this cleanly way of *cooking*. Chops, we are told, can equally well be brought to perfection, and a kettle of water can be seen at any time at the Crystal Palace merrily steaming away.

Electric Communication to Lighthouses.—The members of the Chamber of Shipping for the United Kingdom dined at the Hotel Metrôpole last week, when Sir Michael Hicks-Beach was a guest, and spoke with reference to telegraphic communication with lighthouses and lightships. He said he felt it absurd to suggest that £100,000, or any such sum, would be sufficient, and that he had asked the Post Office to supply an estimate. Though he did not at all agree that the maintenance of lighthouses and lightships should fall upon the national exchequer, he felt that the provision of electrical communication would be a national service, and should be paid for out of the national funds. He was convinced that the country would not grudge a very considerable expenditure in such an attempt to save life at sea when fair and reasonable enquiry had been made as to how that expenditure might be most profitably incurred. The Government would propose to Parliament to make that enquiry.

Manchester Central Station.—Galloways, Limited, Manchester, have received the order for the six boilers and four large engines for the Manchester Corporation electric light installation. The boilers will be 30ft. long by 8ft. diameter, of ⅝in. steel plates for 125lb. pressure, and will be fitted with mechanical stokers as well as double sets of steam and feed arrangements. The engines will be vertical, 17in. and 34in. cylinders, 3ft. stroke, each to give off 360 brake horse-power (or 1,440 in the aggregate), with a piston-speed of 500ft. per minute, and will be provided with special arrangement of condenser. All have to be at work by the end of July. As regards the steam motors for this station, Messrs. R. Hornsby and Sons, Limited, of Grantham, have obtained an order for six tandem compound condensing vertical engines. These engines are to have 10½in. and 16in. cylinders with a 2ft. stroke, and will be constructed to give off 90 brake horse-power, with a piston-speed of 480ft. per minute. The consulting engineer is Dr. Hopkinson, of Victoria-street, Westminster.

High-Speed Electric Railways.—A note in the Institution *Journal* gives some figures by Herr Zipernowski upon his proposed high-speed electric line between Vienna and Budapest, a distance of 250 kilometres—say 150 miles. A speed of 150 miles an hour is proposed, which the author considers the maximum the wheels will stand with safety. The trains would consist of one carriage, seating 40 passengers, carried on two bogies with solid steel wheels 8ft. diameter, the driving power being four 200-h.p. motors, working at 1,000 volts, which necessitates collecting from a raised centre rail, some 600 amperes. The up and down lines would be 11 yards apart to avoid the shock of air when two carriages pass, blowing them off the rails (they ought to be cigar-shaped). There must be no curves of less radius than 3,000 metres—say, 1·8 miles—and for these the outer rail must be raised six inches. The power would be supplied from two stations by alternating current at 10,000 volts, transformed down to 1,000 volts, either using alternate-current motors or re-dressed to direct current.

Salford.—A deputation from the Salford Corporation and Gas Committee paid a visit on Saturday to the exhibition at the Crystal Palace. The deputation were accompanied by Mr. Shoubridge, engineer of the Corporation gas works. Under an order obtained from the Board of Trade, the Corporation are allowed until August next the exclusive right of controlling the supply of electricity for lighting purposes in the borough, and the inspection of the various types of plant now on view at the Crystal Palace has been arranged with the object of enabling the committee to make

some definite recommendation in the matter. It is thought probable that the Corporation will adopt the plan of inviting one or other of the lighting companies to take over their power and carry on the work for a specific period upon terms to be fixed in the contract. In this case the Corporation would reserve to themselves the right of taking up the supply, so that the interests of the ratepayers would in that way be fully protected. On their return to Salford the deputation will prepare a report which will be considered at the next meeting of the Gas Committee.

Liverpool.—At the weekly meeting of the Liverpool Watch Committee, on Monday, the consideration of the question of the city electric lighting was resumed. The Corporation at present have power to purchase from the Liverpool Electric Supply Company the undertaking comprised in the parliamentary order of 1889 at the end of 21 years; they can also acquire the undertaking authorised by the order of 1891 at the end of 42 years. Some time since the company applied for the consent of the Corporation to a provisional order enlarging the time within which the Corporation could elect to purchase the undertaking to 42 years—that is to say, for both undertakings. The committee have decided to recommend the Council to consent to the time being extended to 40 years on condition that the company agree to power being inserted in the order for the Corporation to purchase as a going concern both undertakings at any time after the 31st of December, 1897, upon giving 12 months' notice to the company to that effect. If the Corporation do not elect to purchase the undertaking under the proposed new powers, they will still be in a position to purchase the same at the expiration of 40 years without paying anything for the goodwill.

English Electrical Exhibits at Chicago.—Mr. W. H. Preece, F.R.S., as chairman of the Electrical Department Committee of the Royal Commission for Chicago, has written a stirring letter to members and manufacturers to urge that the electrical department should contain a fine exhibition from this country. An historical collection will be made (including, we believe, the first dynamo machine ever made and the original Atlantic telegraph instruments). A complete lighting station on English methods is contemplated. It is important to show how large a share Englishmen had in developing electrical science. The first electrician was an Englishman, Gilbert. The first practical telegraph was laid by Ronalds in 1816. Davy and Faraday, Cooke and Wheatstone, Wilde and Holmes were Englishmen. The first electric railway was run in England, and nearly all the submarine cables in the world were made here. The artistic developments are carried to a higher degree here than elsewhere. England is to the front with signals and high-speed telegraphy. It is to be remembered especially that large numbers of colonials will visit the exhibition, and England should not miss this opportunity of increasing her hold on colonial trade. Applications for space must be sent to the Society of Arts not later than the 29th inst.

Birmingham Tramways.—A deputation from the Corporation of Glasgow visited Birmingham on Tuesday for the purpose of inspecting the Central Tramway Company's systems of traction, and collecting information thereupon. Mr. Bailie Paton and Mr. D. Rankine, town clerk, headed the deputation. They were met at The Queen's Hotel by Messrs. W. Neale, director; W. Holmden, secretary; C. H. Herring, traffic manager; A. Dickinson, consulting engineer; J. J. Robins, electrical engineer; and R. H. Dickinson, local superintendent. A special car from Navigation-street conveyed them to the electric depôt at Bournbrook, where Mr. J. J. Robins, the electrical engineer, explained the system. They afterwards visited the cable depôt at Hockley, where Mr. A. Dickinson thoroughly explained the working. An amusing and dramatically successful incident occurred when the party entered the electric car at Navigation-street by a passenger (evidently mistaking the gentlemen for the directors) tendering his thanks to them for the splendid service they had provided on the Bristol-road. The deputation returned by the 4 p.m. train, highly pleased with what they had seen of the working of the electric and cable tramways in Birmingham, and expressed their gratification for the information afforded.

Dynamo Buyers.—Having said all they have to say upon the making of dynamo machines, some electrical engineers are taking to giving advice as to buying them. And probably this is not a bad thing to do. For if there is one thing certain in this world it is, that most men think they know their own requirements better than anyone else; and another thing almost as certain is, that very often this is just what they do not know. Now, the buyers of dynamos are to a large extent managers, proprietors, and engineers of works, who do not always know the points of a good dynamo. Instead of simply saying, "Ours is best," therefore, it pays to point out why. We published an article recently on choosing a dynamo, and we notice that another electrical engineer, after having built, bought, and described many dynamos, is also writing advice to dynamo buyers. His remarks embody some good points to indicate to a would-be customer. The dynamo should have stiff heavy standards, a heavy solid base with plenty of metal to give steadiness. The centre of gravity should be low—heating and springing of shafts are sometimes due to vibration. The speed should be low. It should have self-oiling bearings and convenient brushholders. The fewer the bolts and pieces, and the better proportioned the dynamo is as a pure machine, the better for the user; and all this in addition to its commercial efficiency and cost. These matters are all simple enough to the constructors, but it will pay to have catalogues and price-lists that dwell on these advantages for customers to note.

Leeds.—A strenuous letter has been sent on the electric lighting question to the Leeds newspapers from the following gentlemen: Reginald T. Hadow, for the Bank of England; E. Beckett Faber, for Beckett's Bank; Robert T. Haines, for the National Provincial Bank; Charles L. Mason, for the London and Midland Bank; E. Beckett Faber, for the Leeds Club; George Irwin, for the Leeds and County Conservative Club; Henry O. Harris, for Marshall and Snelgrove; as follows: "For months past we have been patiently waiting to take the electric light. Our patience has so far not been rewarded. Many towns of far less importance than Leeds have been long ago supplied with this light, and we cannot think it is the desire of our County Council to keep this, the chief town in Yorkshire, any longer in the background. We confidently call upon the authorities themselves to supply us with the electric light, or to allow terms to electric light companies sufficiently favourable to induce them to undertake the work. We do not ask the County Council to supply the light at an unremunerative rate, but at such a rate as will yield a fair commercial return. We venture to think that it would be a wise policy for the Council to recognise the established character of the electric light, and the desirability of supplying it concurrently with gas." This is a practical way for dealing with dilatory town councils, and should have a decided effect in waking up the authorities who have the central station scheme in hand. We notice in a later letter the agents of the Yorkshire House-to-House Company state that the prospectus of this company will be issued shortly, and comment with satisfaction on the likelihood shown of a large demand.

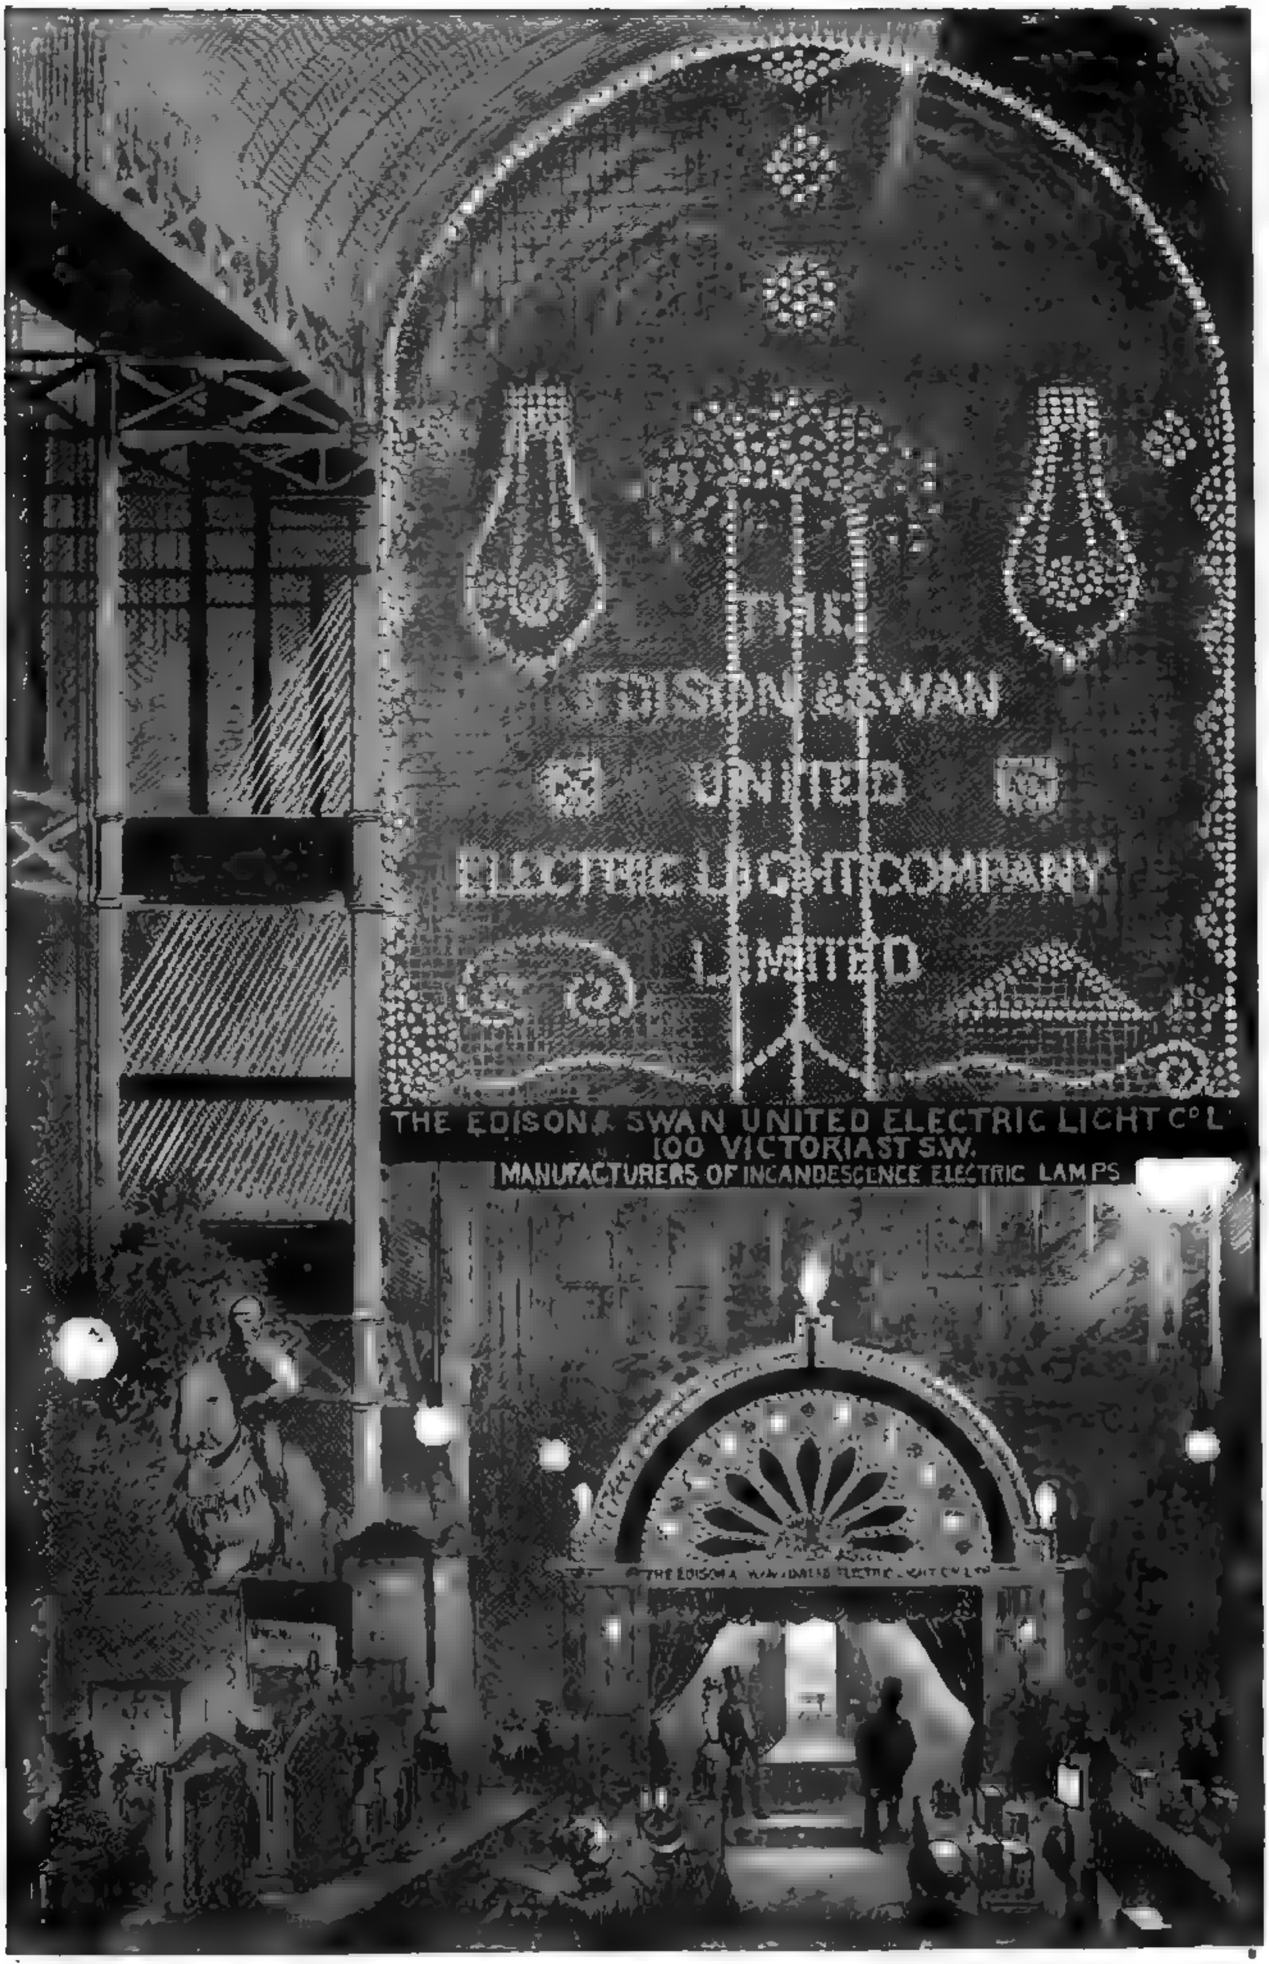
THE CRYSTAL PALACE EXHIBITION.

Mains and Transformers.

We have more than once referred to the energy shown by **Messrs. Gordon and Co.'s** staff in the matter of the central station at Sydenham, and the laying of the cables thence up to and in the Palace. We propose now to give a few details relating to the cable-laying, which will afford our readers some idea of what had to be done. Starting from the central station, three positive and three negative $^{19}/_{14}$ Fowler-Waring lead-covered cables, laid in Archer pipes, convey the electrical energy up to the Palace. The total length of cable is 11 miles, the route taken having been *viâ* those roads in which are the most likely houses to adopt the electric light hereafter. The number of cables will be increased by two positive and two negative, should the demand for light at the Exhibition require it. Where the cables enter the Palace there is a main switchboard, which allows any main to be switched off for testing purposes. Thence the mains are run inside the building to the primary switches of eight 40-unit transformers, the primaries being laid in cast-iron pipes. The pressure in the primaries varies from 950 volts to 1,030 volts, and is reduced in the motor-transformers to 100-110 volts. From the transformers four primaries and four secondaries (all $^{19}/_{14}$ Fowler-Waring lead-covered cable) are led to the centre of the Palace underneath the floor. Running down the centre of the building from the extreme north to the extreme south end, are a pair of equalising mains. Four positive and four negative cables from each transformer are tee'd on to these at equal distances, thus enabling leads to customers to be joined at any point without reducing the section of the main. Between each transformer on the equalising main is a straight through cast-iron fuse-box. Where customers are tee'd off the equalising mains, the feeding mains end in a cast-iron right-angled fuse-box, so constructed that the mains for the stands can be put through a 2in. cast-iron pipe, which fits into a socket in the top of the fuse-box, and is taken through the floor of the Palace. There are three miles of secondary cable ($^{19}/_{14}$) in the building. All the motor-transformers are worked in parallel on primaries as well as secondaries. The work of erecting and connecting up the transformers was only started in the second week of December; in fact, the whole of the cable-laying outside and inside the Palace did not begin until this date, leaving a bare month to complete everything for the Exhibition. Each of the motor-transformers weighs 6½ tons, and is placed in fireproof brick arches in the tunnel of the Palace, the said arches forming the support for the main flue of the building. The temperature in these arches must be felt to be realised. The space, too, is so confined that not even elbow room can be obtained all round the machine. These transformers had to be hauled into position by manual labour on skids over half the length of the Palace in a dark tunnel, where even with the aid of electric miners' lamps it was difficult for the workmen to see what they were doing. Moreover, the whole of the work, both cable laying and transformer moving, had to be carried out against time, the staff working practically night and day, seven days a week, to complete it. It is therefore very greatly to the credit of Mr. G. F. Metzger (under whose superintendence the work inside the Palace was carried out) and his staff, that Messrs. J. E. H. Gordon and Co. were ready on the opening day to supply current. It is still more to his credit that work carried out so hurriedly, and under by no means favourable conditions, should be found to stand without a hitch the test of practical running. We may mention that the work of laying the pipes from the central station to the Palace and the drawing in of the cables was superintended by Mr. C. Watkins, of Messrs. Gordon's staff.

Fire Precautions.

Here we may conveniently refer to the subject of precaution against fire. In the 1882 exhibition several fires broke out, and caused a considerable amount of alarm among the insurance offices. This time, however, we may hope that such accidents will be conspicuous by their *absence, for up to the present not* the slightest outbreak of the most trivial character has occurred, and yet, as a matter of fact, exhibitions like the present one are for many reasons the most difficult to secure against fire. To begin with, a large number of stalls are crowded together, many fitted with drapery and other highly-inflammable material; secondly, there is the difficulty of giving to what is, after all, but temporary work the permanence which would characterise an installation in an ordinary house or building; thirdly, the lighting of the stalls is done with a view to show off special goods, and consequently numbers of lights are employed in a space where only one or two would under ordinary circumstances be fitted up; and, finally, the whole of the wiring has to be carried out in the space of a few weeks—in fact, in a hurry. It is, therefore, no light work that Mr. Heaphy, C.E., of the Phœnix Fire Office, has had to undertake in supervising the whole of the wiring and installing in the Palace, and it speaks well for the confidence which the directors of the Crystal Palace have in his knowledge and practical experience that they should have invited him to supervise it for them. Of course, from the peculiar circumstances of the case, no hard-and-fast rules could be laid down; but it is satisfactory to know that Mr. Heaphy speaks in the highest terms of the way in which Messrs. Gordon and Co., the contractors for the supply of current, and the exhibitors generally have complied with his requests. It has been, in fact, a matter of give and take, in which on the one side it has been recognised that Mr. Heaphy's only desire was to obtain security against fire, while he, in turn, did not forget the peculiar circumstances of the case to which we have alluded above. The chief precautions adopted have been as follows: There is no network of conductors under the floor; all conductors are visible, and are attached to the metalwork of the Palace by porcelain insulators, the idea being that if a fire should unfortunately occur it should not be hidden away where it might smoulder and smoke, and from the fact of its magnitude not being able to be gauged, inspire alarm. A visible fire can be grappled with at once, its dimensions seen at a glance, and it need not as a rule cause much uneasiness even among lookers-on. Wherever possible, all the wiring at the stalls has been encased, and where it could be done without interfering with decorative effects this casing is made visible. Mr. Heaphy has also tried as much as possible to treat each stall as a separate private installation, provided with double switches and cut-outs at or near to the point of entrance of the conductors. In the event of a fire occurring, therefore, at any stall, the Palace staff of attendants would know at once what to do, supposing the stallkeepers were absent—viz., turn off the double switch before applying water. No conductors that have been used before have been allowed, and all must be insulated with vulcanised indiarubber. We have given details above of the work of laying the mains from the generating station to the Palace, under the flooring to the motor-transformers, and thence beneath the entire length of the building. What may not be generally known, however, should be mentioned here—viz., that the floor of the Palace is some 10ft. or 12ft. above the earth in which these mains are laid, and that the earth is wonderfully dry. The consumer's wires are taken off in a cast-iron pipe, through a cast-iron junction-box provided with double cut-outs, one for each wire going into the consumer's stall. Indeed, having regard to the special circumstances and difficulties of the case, the wiring arrangements have been excellently well thought out, and have been rendered as safe as they possibly can be made. In fact, although our experience of this class of exhibitions dates back to the first that was ever held, and includes all that have followed, we do not remember one in which the character of this work, as a whole, anything like equalled that at the Crystal Palace. We congratulate Mr. Heaphy on the result, not forgetting that he has been well backed up and cordially assisted in his endeavours to minimise fire risk by Messrs. Gordon and Co. and the greater part of the exhibitors. We should, perhaps, mention that the Phoenix Fire Office are taking no risks at the Palace, especially as it is well known that the rates have been raised by those offices who do take the risks during the continuance of the exhibition. In face



Edison-Swan Company's Lamp Screen and Stand at the Palace.

of the facts detailed above, and seeing that the wiring and installation work has been carried out under the supervision of a man of such well-known experience as Mr. Heaphy, we altogether fail to see the reason for this action.

THE SCREEN OF LAMPS.

The exhibit of the **Edison-Swan Company** in the North Nave calls to mind the state of affairs, 10 or 11 years ago, at the world-awakening exhibition at Paris. It was there the incandescent lamp broke upon the monotonous discussion of the "division of the light." Our gas contemporaries often refer to the division of opinion amongst electric light engineers. How they used to laugh and chuckle over the diverse opinions about the "division of the light," and intimated that such division was beyond the powers of inventors to devise! But Swan came along in England and Edison in America, both patenting a more or less perfect incandescent lamp, of small candle-power, admirably adapted for interior lighting, and thenceforward it became merely a question of time as to the introduction of such lighting. Few people seem to understand that the natural development of such an innovation is in the first place as a luxury, then, like other fashions, permeating downwards. It was partly due to this lack of knowledge that led to the insane speculative boom of the early eighties, but boom or no boom the luxury was appreciated, and gradually became more and more patronised. The tendency of the extensive use of most things is to reduce prices and increase efficiency. The use of the incandescent lamp has been no exception to the rule. Its cost is now lower and its efficiency greater than it ever was; and as soon as the existing patents run out and the monopoly expires, the price will be still lower. The Edison-Swan Company is not only manufacturing incandescent lamps, but also fittings of all kinds, and in this notice we shall pay more attention to the latter branch than to the former. Before, however, speaking of these we must describe the screen of lamps exhibited, and which our artist, Mr. W. M. Bowles, has delineated in the accompanying sketch. In almost all exhibitions there is some one exhibit which stands out prominently, catching the eye of the visitor, and impressing its effect upon the memory. It will not be too much to say that the *pièce de resistance* of the 1892 Crystal Palace Exhibition will be found in this screen of the Edison-Swan Company. In years to come visitors at other exhibitions will ask, Did you see the Edison-Swan exhibit at the Palace? As an advertisement, then, we hold it to be effective; as an advertisement it was intended, so that it effectively fulfils its design.

There are no less than 32 feeding cables used for the lighting of this screen, which, when its full complement of lamps is on, takes 1,500 amperes of current. The lamps are divided among five circuits, known by the respective devices into which they are made up as the "Border," "Name," "Fountain," "Lamps," and "Star" circuits. The screen is manipulated from an overhead platform erected for this purpose on some of the girders of the building. Here are the switchboards and numerous switches required to effect the rapid changes from one device to another which have proved so attractive to visitors to the Exhibition. There is a main switch for each of the above five circuits, which take about 300 amperes. Each of these circuits again can be split up into 10 of 30 amperes each, by which means a large combination of devices can be arranged.

The usual method of working is, first, switch on the "border" circuit by working the small switches one at a time, until the whole device is complete. Next, all the small switches of the "name" circuit are put down, and the whole of the "border" switched out at the same time as the "name" is switched on, the operator putting down the main switch for the one circuit with one hand and pulling back the other main switch with the other hand, so that the change is instantaneously effected, and the load remains the same. Another circuit is then made ready by the putting down the small switches, and the change made as above described, and so on until the whole of the devices have been shown. The total number of tumbler switches in use is 50, besides five large switches for the device circuits, and two for the main circuit. The filaments of the two "lamp" devices on either side of the screen each have a switch by which either of the filaments can be cut out and flashed alternately—a very pretty effect. We need not go into exact statistics as to the number of lamps employed on the screen. Electrical engineers will be able to estimate the quantity from the current used, but non-technical readers may like to know that the total runs up to thousands. Each of the main device circuits has its ampere-meter, whilst a Cardew voltmeter enables the attendant to see that his pressure is all right. A telephone is provided, by means of which those on the platform can let those in charge of the transformers know when they are going to light up.

Underneath the screen is a handsomely constructed room, the sides of which are fitted with specimens of the company's manufactures, as is also a stand and table running down the centre of the room. Opposite the northern entrance is a very taking exhibit, consisting of a very large lamp globe, the interior of which is filled with about a thousand incandescent lamps of all sizes, shapes, patterns, and colours, being specimens of all the lamps made by the company. Here and there along the filament of the containing lamp, small lamps are lighted to show the direction and position the filament in such a large lamp would take. The right-hand exhibit entering from the north consists principally of fittings, among which will be noticed shades, ceiling roses, switches, etc., some of which we now illustrate. A porcelain ceiling rose and fuse is shown. From this, more often than not, a flexible double wire carries the pendant lamp. The lamp may be ornamented from a variety of shades or globes, some of which are illustrated herewith. A form of fitting and lamp which we understand is largely used, but which we do not admire, takes the form of an imitation candle, as shown. Some of these candle lamp stands are of polished brass, others of porcelain. Their use is illustrated in some of the decorated interiors at the south end of the Palace. The screw and centre contact fittings for these imitation candle lamps are shown in the illustrations, as are the B.C. holder and insulator.

For table decoration we get the fairy lamp shades, and the visitor will revel in a variety of other fittings, which for the present we must leave.

A striking and varied exhibit in the Centre Transept of the Crystal Palace is that of the **General Electric Company**, a large pyramid or column formed of thousands of switches, cut-outs, ceiling roses, and wall plugs, surmounting a large assortment of the most varied electrical fittings, with motors, electric cookers, telephones, and so forth, flanked with large mirrors. The General Electric Company (whose managing director is Mr. Gustav Binswanger) are very widely known as manufacturers and suppliers of almost innumerable fittings for the use and application of electricity in one form and another, more particularly electrical light and telephones. They are more especially wholesale makers, and deal only with the trade. They have many specialities in which they have introduced new features, and in porcelain fittings of "high insulation" type they have some admirable features. They are the English agents for the now celebrated Aron meter; they make large numbers of large switchboards, and in telephony have introduced many efficient appliances, while the domestic utilisation of electricity has always had their special attention. At the Exhibition their goods are shown more for display than for explanation to every passer, so that although such features as the use of motors for shoe-brushing and so forth, and the use of heaters for making pancakes (which we shall describe in a future number), appeal strongly to the visitor, yet the mass of their exhibits are for technical men, electric contractors, and architects. Prominent among these fittings, of course, are switches and switchboards. Some of these we illustrate herewith.

The "Link" switch for mains or branch wires is an extremely good type of switch for ordinary use, for either large or small currents. It is of the rocking handle or "tumbler" type, but has a peculiarity in the link action, which, when the handle is pulled back, either locks the contact in place or springs it off with a sudden break. As will be seen from the illustration, a contact bar, pressed up strongly by spiral springs, has a little loose link in its centre. This is connected to the bar of the handle. When the handle is pulled back the bar is forced between two stout split contact springs, and so makes contact. The contacts for the cables, instead of being of

the type where the conductor is twisted round and pressed under a nut, is made of a hollow socket, admitting the conductor, in the case of the main switch, from the back, having side-set screws for binding the cable. The main Link switch is made in sizes from 50 up to 1,000 amperes, in heavy gunmetal. The same principle is applied to smaller switches, which are made in two sizes, to carry five and 10 amperes, suitable for 1—8 and 1—15 lamps. The main switches are made with slate bases, the branch switches usually in porcelain, with either porcelain or brass covers.

simply in a collection of different switches with their cut-outs mounted usually in a glass case, as shown. Almost all modern buildings are now fitted with some such system as this. Except private houses, where the owner may prefer to have separate switches on the walls of the room or in the holders, it is more usual to turn on all the lights from a distributing switch; and in public offices, banks, and large buildings, a man having charge of the key of the case goes round before dusk and turns on the switches.

The "Link" switch is comparatively new, but another type, to which the name of "Byng" switch has been given, has been in use for many years. It is a double-break switch, and is made in a variety of patterns, plain or ornamented, and painted in artistic fashion, as shown in our illustration. They are also shown with brass covers.

The General Electric Company make up numerous varieties of switchboards, using their switches, ammeters and voltmeters, and cut-outs mounted on slate bases. A new type of switchboard now much in use is the corridor switchboard, used for lighting buildings which are connected to the street mains of a central station. It consists

the General Electric Company have introduced, consists in the adoption of special precautions in the china bases of wall plugs, ceiling roses, and cut-outs—always the most troublesome part of the installation. In all the fittings on the H.I. system there are these special safeguards: A wall or plug of china divides the two ends of the flexible wire; and no screws, or metal, or other connections pass through to the back of the base-plate. The first prevents the loose ends of the flexible from making a short circuit, and the second prevents any dampness in the wall from affecting the insulation.

The wall plug on the H.I. system is shown in our

illustration, and embodies some further improvements. The great difficulty in wall plugs is to get them to fit together at once, and also to prevent all sparking. This is difficult to obtain in the two-prong type. That shown is made with concentric contacts, and fits easily and at once into place, with no danger of sparking. There are, moreover, no projecting prongs to get in the way. As will be seen, the socket has a split ring standing out in air, in the centre being a split pin. The plug fits on this, and makes contact with its stem inside and out. These wall plugs are very strongly and substantially made, both as regards the china and the contacts. It must be remembered that being

movable they are at the service of everyone, and are used to connect a lamp, a chandelier, a motor, or a heater, and often have to carry five times their usual current.

The "H.I." ceiling rose is also upon the same patented pattern. All the connections are on the front of the base, as seen in the illustration. The flexible comes through the holes in the plate, and the wires go one to the right and the other to the left of the porcelain T-piece. This fitting also embodies the principle strongly advocated by the makers of these fittings, that any fitting from which the current is led by a flexible, should have a cut-out. These places are more liable to short-circuit than any other position, and each should have its cut-out. In all these

to separate the different wires of the flexible, which are connected to terminals at each side of a china partition. Another pattern of lampholder with the same kind of china socket is used for the loop lamps with spring holders.

The General Electric Company show also a number of ammeters and voltmeters made on the Donnison principle in their Manchester works. This principle depends upon the fact that an electric current passing circularly or spirally in a helical coil produces an interior magnetic field of varying strength—*i.e.*, the nearer the side of the core of the solenoid the stronger the field, the centre having the least number of magnetic lines passing. Any piece of iron pivoted eccentrically will tend to move into the stronger

fittings, therefore, cut-out screws are inserted, and being there contractors generally put the fuses in.

The separate cut-outs on the "H.I." system are also shewn. In these the wires go straight through the block and are connected to screws, the screw passing through the separating porcelain piece, and the cut-out or fuse wire is inserted on the opposite side. These cut-outs are made both single and double pole, and also combined for a distributing-board. In the distributing-board now much used for the separate floors of houses, the main comes to one pole and the branches are connected to the others, the fuse wires stretching between.

In the bayonet lampholder, known as the "Belsize" holder, china supports are made on the "H.I." principle

magnetic field. In the Donnison instruments a piece of best charcoaled iron, carefully annealed, is pivoted eccentrically with regard to the axis of the solenoid, so that it will tend to move radially from right to left with regard to the centre of the solenoid and the face of the dial, carrying an aluminium pointer with it, from the left to the right hand. The movement of the pointer is controlled by gravity. The advantages of these instruments are that a scale can be obtained that is well proportioned, and between any two divisions of the scale at which the instrument will be usually working, the movements of the pointer can be greatly magnified. The resistances of the voltmeters are self-contained up to 300 volts. For higher reading instruments separate resistances are provided.

THE "JOURNAL OF GAS LIGHTING" v. ELECTRIC LIGHTING.

The calling a spade a spade has usually been considered an attribute of bluntness rather than a characteristic of politeness. It is as impolitic, however, to hit a burglar with a cane when a bludgeon is handy, as it is to encounter some critics with soft words. Our contemporary the *Journal of Gas Lighting*, full of mistaken zeal, animated by the appearance of truth, arrogates to itself a weekly censorship of all that concerns electric lighting. It has for years so imposed upon itself by endeavouring to pick holes where none exist, that at length it has reached the critical period of assuming the facts and fancies of its own imagination to be realities with a tangible existence. It has so long been forming conclusions upon half-truths, that it has lost the power to dispassionately discuss whole truths. Last week a challenge was thrown to "electrical contemporaries," which at first we felt indisposed to take up unless the gas journal better defined its own position, but acting upon our motto that whoever is not aggressive ceases to be progressive, we will consider the merits of the case. The gas journal takes the figures of Colonel Makins given at the meeting of the Gas Light and Coke Company, and says: "We should esteem it a favour if our electrical contemporaries would let us and the world know their opinion of these figures, taken in conjunction (say) with Mr. W. H. Preece's remarks about the marvellous effects that have followed the introduction of electric lighting into the Post Office." Mr. Preece has again and again given the figures relating to the actual cost of the Post Office lighting, and also the fact that since its introduction the average absence through illness of the employés has been shortened—figures and facts that are official, which have not and cannot be impugned—so that we may safely leave this part of the challenge till our contemporary disputes the accuracy of the official statistics. The figures of Colonel Makins are in a different category. We assume their correctness, and give reasons for the deductions we derive therefrom. The following we presume are the figures referred to by our contemporary. We take them from the *Times'* report :

"They had very carefully looked into the electric light question as it affected them. The most important electric lighting district was formed of what he might call the Bond-street quadrilateral—Bond-street, Regent-street, Oxford-street, Piccadilly, Pall-mall, and the Strand. Their rental from that district in 1889 was £77,675, when the electric light was more than beginning to make itself felt; and in 1890 the amount fell to £74,947, and last year to £73,538. They had thus lost in a district which was more electrically lighted than any place in the world £4,000 of rental in three years, while the increase in their rental all over their district for last year alone was £92,000. He might say further that they had got out a list of typical consumers in every part of their district—the Houses of Parliament, Marlborough House, the British Museum, the General Post Office, banks, clubs, places of amusement, and large tradespeople;

and he found, dealing with this list of eighty-one consumers, that the rental which they paid the company three years ago was £91,363, two years ago the amount was £88,323, and last year it was £87,847. This showed, again, that they had lost £4,000 in three years among all these great consumers of the electric light. He thought they had conclusively proved that the electric light was a light of luxury, and was used only by those who did not care about the question of cost. He might say that out of their 215,000 or 220,000 customers only 2,600 used the electric light, or less than 1¼ per cent."

According to these figures, Colonel Makins and our contemporary assume the total loss due to competition to be £4,000 in three years. That is a convenient assumption, and very gratifying to the gas interest. Why, then, should we envy them the pleasure they derive from the consideration of these figures? We should not take the trouble to show the incorrectness of their conclusions were it not for the challenge they themselves throw out. Our contemporary must think it has to deal with a lot of unsophisticated people, if it hopes to obtain credence in its conclusions. It will be seen that Colonel Makins speaks of this district as a most important lighting district; hence, we may safely assume that the consumers are large consumers, and upon this we are asked to believe that 2,600 consumers only spent £4,000 per year upon lighting during a period of three years—that is, just over 30s. per consumer per annum. Upon the face of it, this is utterly ridiculous. The way to arrive at the true loss would be to collect all the bills these 2,600 consumers paid for electric light, and the total amount would give the loss to gas. It is needless to discuss whether a man pays more for the electric light than he does for gas. If he gets what he wants from gas, he is ready to pay the same price as for electricity. From what we know of the district under discussion, we should imagine the collective bills of 2,600 consumers would be nearer £50,000 over three years than the amount assumed by our contemporary. As we have hinted before, this gas journal delights in half-truths, or the untruth which is more difficult to encounter than the downright whopper. Let us try these figures another way. According to one of the experts at the meeting, if the gas company's affairs were properly conducted there ought to be an increase in consumption—say of 7 per cent. since 1889. Now, if we accept this dictum, the income in 1891, instead of being £73,538, should have been about £83,000—a difference of £10,000, not of £4,000. We have no wish to be hard upon our contemporary, nor do we desire to show up in detail its rather blind rushing after inferences. It will be sufficient for our present purpose to indicate how different an interpretation can be placed upon the figures given by Colonel Makins than that intended when they were put forward. Surely in this case the moral will be learned, that in future it will be better for those interested in gas to deal with generalities and trivialities, rather than to give figures which may be used t'other way. This humble advice, by the way, is not offered to our gaseous contemporary, because it long ago showed that it would heed no morals and draw no inferences but those which happened to suit its particular purpose.

CANTOR LECTURE—No. 4.

The last lecture of this series of Cantor lectures was delivered by Prof. Forbes on Monday last. The lecturer dealt with two interesting subjects in the utilisation of water power and the use of destructors for electrical purposes, taking his text with regard to water power from the experience at Geneva, where turbines are used on the Rhone with a fall of water of only 6ft. to 12ft. to pump up water to a higher level. This high-level water is that used to actuate the machinery of the town, and although the central lighting station is near the low-pressure turbine station, the power used in the station is that supplied from the high-level reservoir. To drive home his moral, Prof. Forbes suggested what might be done at Edinburgh. Assuming a maximum output of power required at the central station of 1,000 h.p. for two hours as being the same as an average continuous output of 150 h.p., he pointed out that the existing loch on the top of Arthur's Seat, at Edinburgh, would about provide water for 1,000 h.p. for two hours, and could be made to give double this by the erection of a by no means objectionable dam. To keep the head of water required, engines of 150 h.p. would be used to pump, and pipes led back to the central station to bring the water to actuate the turbines. In other words, Prof. Forbes's scheme for lighting Edinburgh is to pump up water to the loch on Arthur's Seat by engine power, to use the water so pumped to drive turbines which would drive the generators, and he states that his estimates show this to be an economical plan. It may be remarked that 1,000 h.p. would not go far towards lighting Edinburgh. At the most you might obtain 7,000 16-c.p. incandescents, or 14,000 8 c.p. This, again, might allow the wiring of 70,000 of the one, or 140,000 of the other, if we assume that only one lamp in ten is using current. It may, however, be safely stated that this proportion is too small. The lighting of Edinburgh would require more horse-power than was mentioned in the lecture, but no doubt Prof. Forbes only referred to that part of his scheme connected with the special point he was urging on his hearers. A description of the "destructors" in use by various local authorities was next given, Prof. Forbes concluding that the destructor in Kidacre-street, Leeds, was the best he had examined. A certain amount of heat generated in these destructors can be usefully employed, and Prof. Forbes's moral was contained in the suggestion that a combination of the Geneva plan with the utilisation of the heat from the destructor would in many cases be found economical. Thus, supposing 150 h.p. could be obtained from the destructors, engines of this capacity could be continuously pumping water into a high-level reservoir. The water so pumped could be used by the central lighting station for its turbine, and a maximum of 1,000 h.p. obtained for lighting purposes for the

busiest hours of the lighting day. This combination will be new to many electrical engineers. We think more mention might have been made of the excellent experimental work of Mr. Bennett at Southampton. In 1889 Mr. Bennett read a paper before the Municipal Engineers explaining how he had used, and proposed further to use, the waste heat from the destructors at Southampton. We have occasion also to know that the use of destructors has been carefully examined by other electrical engineers, and more than one local authority is at the present moment discussing schemes founded on a use of this apparatus. Prof. Forbes's lecture will prove useful in causing more general attention to be given this subject.

UNDERGROUND MAINS.—XI.

JOHNSTONE'S CONDUIT SYSTEM.

The Johnstone system of electric conduits has long been in use for underground mains in some of the principal towns of the United States, such as New York, Philadelphia, and Chicago. There are already over 150 miles of cable laid on this system, 111 miles of which are in New York. The system is now being introduced into England by the International Electric Subway Company, of Albany-mansions, 39, Victoria-street, Westminster, where a complete and full-sized installation is to be seen; and as it seems to be an eminently practical system suitable for large companies, and especially for corporations wishing to keep control of their streets and subways, we make no apology for describing it in our series of systems of underground electric mains.

The essential idea of the Johnstone system is the use of ordinary insulated cables in cast-iron conduits of such a nature as to allow many sets of mains or wires to be laid together without being confused, and to allow of jointing for distribution at any point with the minimum disturbance of the roadway. The conduit is made entirely of cast iron, produced without machine work, and is, therefore, especially for large distribution networks, of economical cost.

The conduit is built up, piece by piece, in the form of a cast-iron trough, composed of two sections, laid one upon the other, the edges being tongued and grooved, and when laid in the streets, jointed with putty or cement. In the interior of the trough so formed, trays of cast iron are slid in, each tray bearing on its upper surface grooves into which separating slips of cast iron are also slid. In this manner continuous ducts are formed to the number desired, into which the cables can be laid or drawn. In order to give the utmost facility for jointing, this cast-iron troughing is made in 5ft. lengths, and at any place a section cover can be lifted and a jointing piece or spigot can be inserted for distributing or service mains. In practice the two sections, top and bottom, of the trough or conduit are laid so as to break joint; a joint therefore comes at every 2½ft. The troughs are kept in position in the simplest way by lugs cast on the sections, which interlap, and are fixed simply by knocking in a wedge.

To ensure joints being water-tight, all grooves, recessed clamps, and abutting ends are filled with putty. With this joint the longer it is immersed in water the harder the joint becomes. The reliability of this method for making a water-tight joint has been tested by long experience.

Distributing-boxes or hand-holes are placed opposite every building or party wall, but this not done usually until the conduit is complete. The pavement is dug up and the conduit first laid in blank, so as not to necessitate the trench being made larger at any one place. When the time comes to connect the house, the blank cover is removed, and a specially cast cover with spigot is inserted. In this way the wires can easily be got at, either to repair, test, or join up house services. All the covers are interchangeable, and if, needed, the connection with the main can be made from the underneath. The spigots can be turned round and the joint made from either right or left hand side as desired.

Manhole of the Johnstone Conduit System.

At central positions such as the intersections of streets, a large pit is dug and an iron manhole is built. This iron manhole has been adopted both as being very substantial

and preventing the introduction of moisture. The manhole is built up of various circular cast-iron rings, grooved and jointed as are the troughs. These rings are of several sizes, and some are made with openings for connecting to the conduit itself. These are termed the spigot rings, and it can be seen that such an arrangement allows the mains to be taken off at any height and in any direction with the minimum of previous arrangement or trouble. The spigot rings are all of uniform size, and various-sized conduits are made to fit the same size of spigot. Above the last ring of the manhole is placed a tapering hood, or top, made of sufficient strength to take the strain of the street traffic. The manhole is closed first by a cover to exclude moisture, and above this by a grooved foot-plate laid flush with the level of the street. The manholes are very large, and it might, perhaps, be possible to place transformers in them in certain positions. The rapidity with which the manholes can be built up and the conduits laid along the streets is evidently a point in its favour.

Johnstone Electric Conduit System.

The illustrations we give are taken from work as actually carried out in New York. Any cables can, of course, be used—ordinary insulated, concentric, and for light, power, telegraph, or telephone.

In connection with the Johnstone conduits there are three points to which particular attention is directed—(1) facility for distribution, (2) accessibility, (3) the use of cast iron throughout.

The Johnstone system is especially convenient for distributing wires at any point in the circuit because of the sectional structure of the conduit, which enables a junction-box to be inserted at any time by simply removing a 5ft. section and replacing it by another supplied with a hand-hole opening or distributing-box. This feature is very advantageous in street lighting, where it is often necessary to make joints at points not provided for when the mains were first laid. It is equally easy, as is seen, to distribute from the top or bottom, or from either side.

In making a joint at the hand-hole used in this system, provision is made for laying the necessary splices out of the direct line of the conduit which contains the cable, thus avoiding any danger to the splice, which naturally increases the size of the cable at that particular point. This device consists of the projecting casting or spigot attached at the time the connection with the house is made. It extends outside the line of the conduit, and prevents the possibility of any injury being done to the splice by a push-rod for the purpose of drawing in other cables in the same duct.

The second feature in the Johnstone system is its accessibility. As it is impossible to insulate wires with such perfection that defects will not occur at some time or other in a conduit carrying a high-tension current, the question arises how to do the necessary repairs at the least cost, and with as little delay as possible. One of the great advantages of the 5ft. sections is that in the case of a defective wire, the exact position of which is known, the 5ft. top section can be removed, if necessary, all the partition shelves taken out, and the cables that are in use allowed to swing or suspend from their respective ducts over the open place; the cable can then be repaired. This operation disturbs only the defective cable, avoiding the laborious and expensive work of drawing the cable out from one manhole to another. After the repair is made the partition shelves can be slid into their original position, the cables adjusted in their ducts, and the top section replaced, making the conduit equal to its original condition.

In most devices for underground conduits the only way a cable can be reached for repair, after it has once been laid, is by removing bodily or drawing out the damaged cable, the former necessitating the expense of digging up the street or pavement from manhole to manhole, or whatever the distance may be.

In any pipe system of conduits the fact of screwing one pipe into a union joint, or any device used as the equivalent of a union joint, is very likely to throw upon the inner surface of the pipe sharp edges which are liable to cut or damage the insulation of the cable when it is being drawn in. This is avoided by the use of the ducts.

The sections are perfectly fitted together, so that each line of ducts forms a smooth uninterrupted casing through which

cables can be drawn without the possibility of injuring the insulation.

This construction, moreover, conforms to the present Board of Trade regulations—viz., that when high and low tension mains are carried in one conduit the cable must be entirely surrounded by a metallic conductor and each have its own compartment. Lead-covered electric light cables in an insulated conduit are regarded as highly dangerous. Assuming that a conduit is constructed of an insulating material, and that the cables are lead-covered, the lead covers of these cables are in such a case conductors, each one of which might be charged to a very high potential. Such conditions would prevent jointers doing their work with any degree of safety, and would make underground work much more dangerous than overhead.

These conduits have been down in America and in use for over five years, and are understood to have given great satisfaction.

The conduits are manufactured in different sizes to meet the requirements of electrical services of various descriptions, and in price they compare favourably with the methods now in use.

Types F and G are cylindrical cast-iron pipes, 3½in. by 6in. respectively in diameter; the pipes are cast in two equal longitudinal parts, they are grooved and fastened together with keys and wedges. They are in 5ft. sections, and furnish the same facilities for distribution and access as the larger types, and like them have a perfectly smooth inner surface.

The Johnstone system of electrical underground conduits evidently provides for every requirement of electrical underground service in any desired quantity and of every description—viz., telegraph, telephone, electric light, electric power district messenger, and fire alarm service, the cables and wires of which are all times accessible at any point along the line of structure.

We understand that negotiations are in progress for the immediate laying down of a set of distributing conduits on this system in a large English town which is intending to introduce the electric light.

Electricity in the Workshop.—A fine example of the extended use of electric motors for all manner of purposes in the engineering workshop is given in a recent description (February 3rd) in the New York *Electrical Engineer*, with illustrations of the Edison Schenectady works—power-house, electric crane, electric derrick, electric hoist, electric blower, electric elevator, electric shunting locomotive, motors driving drills, pumps, lathes—the electric railway round the works, and the boiler-shop, all run by the universal electric motor. These are the kind of instances that convert practical engineers to belief in the *motor*.

A DESCRIPTION AND COMPARISON OF THE METHODS OF ELECTRIC LIGHTING AT PRESENT IN USE IN LONDON.*

BY ALEXANDER B. W. KENNEDY, F.R.S., M.I.C.E., ETC.

(Continued from page 165.)

The "transformer" used with alternating currents is based on the following phenomena: If two conductors of a suitable kind, and forming part of closed circuits, are placed near together and parallel, but without any contact (that is, completely insulated from each other), and a current be passed through the one, at the instant of starting it a current will be found to traverse the other. This latter current (which is called an induced current) does not continue, whether or not the originating current goes on steadily; it is instantaneous only, occurring just at the instant of starting. But at the instant when the first or primary current ceases, another induced current appears in the second wire, this time in the opposite direction to that in which it formerly appeared. If, therefore, the primary current starts and stops 80 times per second, the induced or secondary current will be a similar discontinuous current having the same frequency and therefore available for the same purposes. If the primary and secondary wires be alike, the tension of the two currents as well as their quantity will be the same. By using, instead of a straight wire, the helix of a certain number of turns to form the primary, and for the secondary another helix containing a different number of turns, the induced current may be made either higher or lower in pressure than the primary. The quantity of current, of course, varies inversely as the pressure, so that the amount of energy transmitted is not altered, except so far as internal losses affect the efficiency of the apparatus. In principle the transformer is simply a pair of coils such

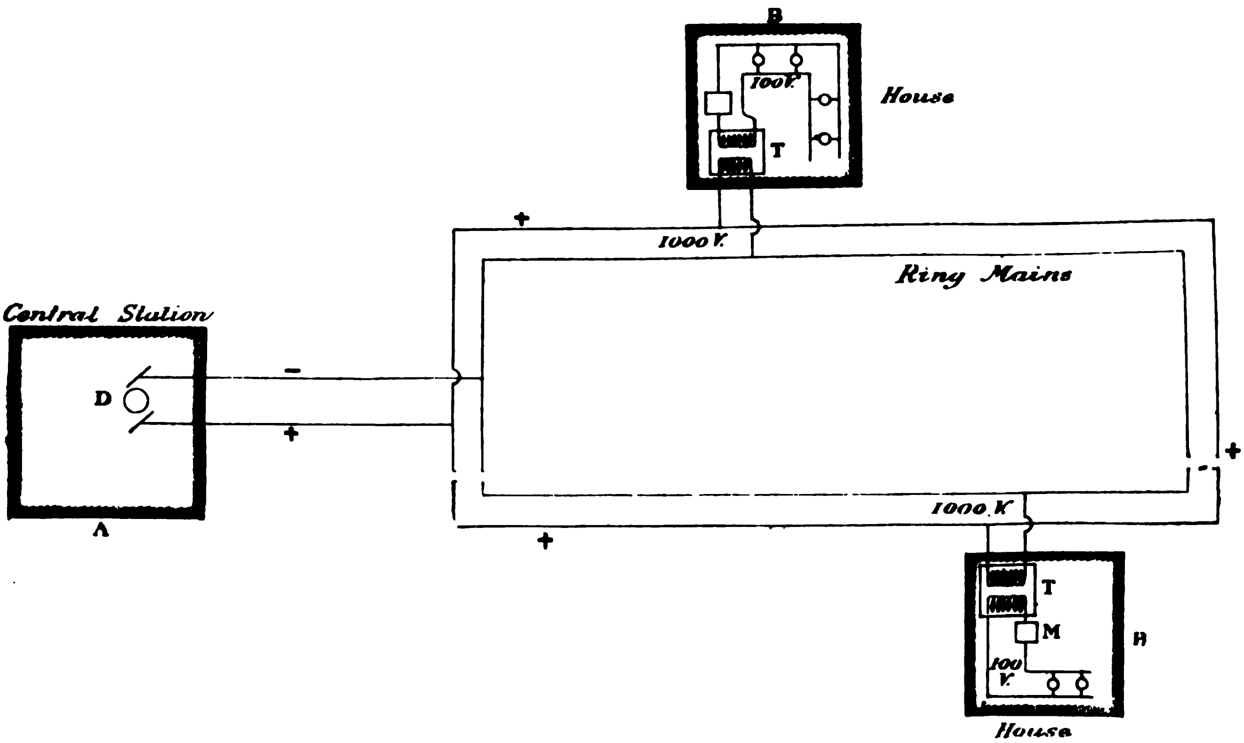

FIG. 1.

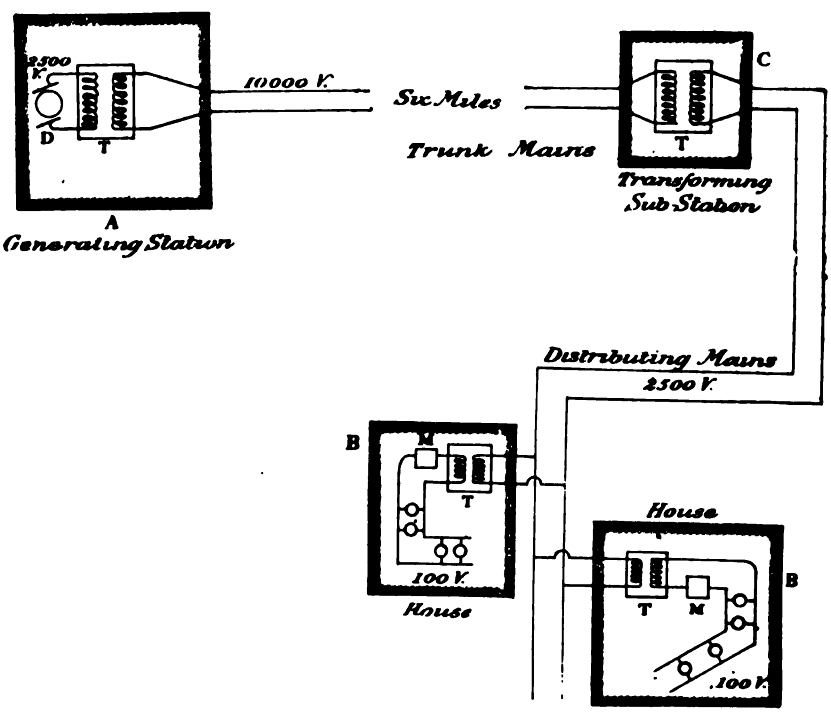

FIG. 2.

* Reprinted from the *Transactions* of the Royal Scottish Society of Arts, vol. xiii., part 1. Read May 11, 1891.

as I have mentioned. Remember that there is no electrical contact whatever between the coils, although they may be in very close proximity. The high-tension main goes from the station to the primary coil of the transformer and back again to the station without actually entering the house. The low-tension main goes from the secondary coil of the transformer round the house circuits. Apart from accidents, therefore, the high-tension current can never actually get into the house mains. Fig. 1* shows the general arrangement of the circuit and transformers used by the Metropolitan Electric Supply Corporation. A is the central station from which a series of circuits are led through the district. D represents a dynamo, with its two poles connected to one of those circuits. It will be seen that soon after leaving the station both positive and negative wires are looped into rings; the ring may, of course, embrace many streets. B B are houses in the district to be supplied with current. There is a transformer, T, and a meter, M, in every house. Wires from the mains enter the transformer, pass through the primary coil, and come out again. The secondary coil is shown separately connected with the lamp circuits of the house. The meter by which the electric energy is measured is on the house circuit. The pressure in the mains is 1,000 volts, the pressure in the house circuits may be either 100 volts or 50 volts, according to the wish of the consumer. Mr. Frank Bailey, the engineer to the company, is of opinion that a 50-volt house circuit is better than a 100-volt house circuit, from the view at any rate of the life of the lamps. The system of looped mains shown in the sketch is due to Mr. Bailey, and has been adopted so that every house on a circuit can be reached round the loop in two ways, thus greatly reducing the risk of breakdown through an accident on the mains. One or more circuits may be connected to and worked from the same dynamo at the station, but at present it has not been found possible here to put more than one dynamo on to the same circuit, or, in technical language, to run the dynamos in parallel.

The system adopted by the London Electric Supply Corporation, which has been from the commencement designed and worked out by Mr. Ferranti, differs from that just described in very many respects. Its general scheme is sketched in Fig. 2. This company has, rightly or wrongly, assumed that it was advisable to make its station away from London. Its generating station is on the Thames at Deptford, about six miles from Charing Cross. Current is there generated by large dynamos at a pressure of 2,500 volts. It is transformed at once up to 10,000 volts, and transmitted to London at that pressure by specially insulated mains of most ingenious construction. These mains lead to two or three sub-stations in London itself, one in Bond-street, one near Charing Cross, etc., which contain transformers only, and where the current is transformed down to 2,500 volts again, and distributed at this pressure through the streets. In the customers' houses it is transformed down to 100 volts, just as in the last case. It is intended ultimately to generate current at the full pressure of 10,000 volts so as to save the first transformation. There can be no doubt that with such appliances and knowledge as we possess at present the drawbacks of having three transformers are very great indeed. Whether or not they are more than counterbalanced by the advantage of having a station down the river is a matter which must finally be decided by the result of practical working.

The system used by the House-to-House Company does not differ in essentials from that of the Metropolitan Electric Corporation, except that the pressure in the mains is 2,500 volts instead of 1,000.

I have said above that the transformer was the trouble as well as the blessing of the alternating-current system. Whilst it enables a saving to be made apparently throughout the whole of the mains, this saving is accompanied not only by the very notable cost of the transformers, but also by such a very great loss in efficiency that it is now most improbable that any new high-tension company will be started in an urban district on any of the plans I have described—that is to say, with a transformer in the house of each customer.

ELECTRIC TRAMWAYS ON THE OVERHEAD OR TROLLEY WIRE SYSTEM.*

BY W. GIBSON CAREY.

The idea of propelling vehicles by means of electric motors does not appear to have received any serious attention until about 50 years ago. In 1840, Henry Pinkus, of Philadelphia, applied for and obtained a patent for a system of electric propulsion of vehicles, which closely resembles both the open-conduit and the double-trolley systems. He proposed to use a continuous slotted tube or conduit, supported alongside the track and containing two conductors, from one of which the current was to be taken by a sliding contact and suitable connecting conductor to the motor on the car, and through the other of which it was to be returned to the generating station. It need hardly be said, however, that owing to the imperfect state of the motors of that day, nothing practicable came of this scheme.

Some experiments in electric railways were tried in Berlin in 1867 by Dr. Werner Siemens, but it was found that the Siemens machine as then constructed heated excessively, and the work was temporarily abandoned. In 1879, however, the same experiments were resumed with more successful results. In that year Messrs. Siemens constructed a line 500 metres in length at the Berlin Exhibition. The main conductor in this case was a central rail, the outer rails completing the circuit back to the generating station. Prompted by the success of this venture, similar attempts were made at Brussels, Dusseldorf, and Frankfort with equal success, and two years later Messrs. Siemens put down a permanent line at Lichterfelde, near Berlin. While the Siemens were engaged in their experiments in this direction, Charles J. Van Depoele, Steven G. Field, Thomas A. Edison, and several others were working on the same lines in America, and at the end of 1882 a railway, which was the result of eight years of constant experiment, was put down by Mr. Van Depoele at Chicago. After this Van Depoele, Daft, and the Bentley-Knight Company built roads in quick succession at Toronto, Baltimore, New Orleans, Cleveland, and many other places. But in spite of the rapid progress that was made, as a result of the experience gained on these installations, it cannot be said that the electric railway became a practical commercial success until 1888, in which year Bentley and Knight built the Allegheny City road, the Sprague Company equipped the road at Richmond, and the Thomson-Houston Company, who had by then acquired Van Depoele's patents, built the Eckington and Soldiers' Home road in Washington. On January 1st of that year there were in operation in the United States 13 electric tramways operating 98 motor cars, on less than 50 miles of track. Three and a-half years later the country could show 354 roads, operating 4,513 motor cars, on nearly 3,000 miles of track. During the last six months fully 50 more roads have been added to this list. Such has been the growth of electric traction in four years.

In Europe, on the other hand, the rate of increase has shown scarcely any improvement. A new area of progress appears to be opening now. Several Siemens roads, and the great Bremen system, which is to be equipped throughout by the Thomson-Houston Company, in Europe, and recent installations in England, promise to be the nucleus of a list of electric tramways on this side of the Atlantic, which will before very long rival in importance those of the United States. The early inventors first turned their attention to open conduits, and as long as the lines were purely experimental ones, constructed on private grounds over which there was no general traffic, and which was already thoroughly drained, there appeared to be no difficulty in maintaining the conductors in satisfactory condition. As soon, however, as it was attempted to apply the conduit to conditions of actual practice, unforeseen difficulties arose from the impossibility of excluding dirt and moisture. In the United States alone, at least four practical experiments have been made in this line, and many thousands of pounds expended in efforts to construct railways upon this principle. The difficulties with which each attempt met naturally turned the attention of the pioneers to overhead wires, which were found to be entirely

* **Paper read before the Royal Engineers.**

free from the objections to which the conduit was open. Æsthetic considerations, however, forbade the adoption of a system involving lines of poles and overhead wires in public streets, until every means of avoiding it had been tried and found inadequate, and again and again inventors returned to the search for some method of underground transmission of power. The experience, however, of Van Depoele, Bentley and Knight, and many others, has left us little reason to hope that a continuous live conductor in an open-slotted conduit can ever be made a success in our city streets, its fatal weakness being the impossibility of keeping the conduit free from mud and water.

Much thought and labour have been expended in the attempts to produce a system of closed conduits, having an insulated main conductor with a series of points or plates upon the streets surface, which are brought into contact with the main conductor one at a time as the car passes over them. None of these schemes have been extensively tried, but it is scarcely possible to look for anything but failure as the fate of any of them, unless some scheme can be devised where the insulation of the live parts can be maintained. This has not yet been done. Even if dependable automatic devices prevent the contact points from being in contact with the main conductor all the time, if the conduit is filled with mud and water, and the points are made alive during the passage of the car over them, there will be a momentary grounding of these points, and the result will be, if perhaps not so severe a grounding as that to which the open conduit is liable, at least one bad enough to cause fatal disaster both at the power station and on the line. If such a system as this can be perfected, the field for electric traction will at once be enormously widened, for it cannot be doubted that many communities are deterred from adopting it only by their prejudice against overhead wires.

Attention was early given to the propulsion of tramcars by means of accumulators, but although improvements have from time to time been made in the batteries, by which greater weight, efficiency, and longer life have been secured, the cases in which the storage battery car can render satisfactory services are few and far between. The load diagram of an electric car in actual service on the curves and gradients which it must encounter in our city streets shows such enormous variations, that provision must be made for the supply of fully seven or eight times the average current consumed. A car which nominally will take 7 h.p. or 8 h.p. may momentarily require, when starting on a heavy grade, 60 h.p. or 70 h.p. Motors of half of this maximum capacity can readily stand such unusual demands when made for only a few moments at a time, but no battery that has as yet been devised can stand anything like this rough usage without very rapid deterioration, and it is impossible to supply the requisite amount of surplus power in cells without adding prohibitive weight. Ample experience has proved that the storage battery has not yet, commercially at least, been brought to that point at which it can successfully meet the requirements of anything but absolutely level lines, and these in urban tramways are scarce indeed. It is of course earnestly to be hoped that the efforts of those men who are working in this direction may soon be crowned with success, and no one will more gladly greet the advent of a practical storage cell than the manufacturing companies who are exploiting the trolley wire.

Even the practical American at first objected to the erection of poles and the stringing of wires through the streets, but the necessity for rapid transit which became greater and greater as the growth of the cities made it necessary for business men and workers to live further and further away from the places of their employment, made some substitute for the slow horse-car an absolute necessity and they early saw that the choice lay between rapid transit with overhead wires and the expenditure of valuable time in travelling back and forth between their business and their homes without them. The installations at Boston, Washington, and Richmond (Va.) called the attention of street railway officials throughout the country to the cleanliness, reliability, flexibility, and economy of the overhead electric system, and the opportunity which it offered them to supply the public with rapid and comfortable transit at a reduced cost was at once eagerly embraced upon an enormous scale. Great pressure was brought to bear upon local authorities and upon public opinion, and local consents were quickly obtained in every city of importance throughout the country. The patents of the principal inventors, which until then had been owned by a few men of small capital and little influence, had by this time been taken up by large and very rich corporations, and upon these orders now began to flow in for tramway motors at a rate which severely taxed their output capacity. European conservatism and the fact that the advantages of electric traction have not been properly brought before the public have up to now prevented its adoption on a very extensive scale. As has been pointed out, this conservatism and apathy are now beginning to give way, and we may soon expect to see the advantages enjoyed by the Americans within the reach of the citizens of many of the prominent towns on this side of the Atlantic.

This brief view of the various methods of applying electricity as a motive power for tramways has been necessary to show the reasons for the almost universal adoption of the overhead or trolley system. Experience has proved no point more strongly than the necessity for absolute thoroughness and as near an approach to perfection as can be attained, in both design and workmanship, of every detail. No class of machinery is subjected to more severe and constantly recurring shocks than electric tramway apparatus, and no detail, whether of power station, line, or rolling-stock can be too good, and nothing short of the best obtainable should ever be used. It is poor economy to instal cheap and flimsy apparatus, which will from first to last cause endless vexatious accidents and swell the repair bill to proportions that will far outweigh the interest on a more liberal investment.

In considering electric tramways, it is customary to divide the subject into and consider it under the following heads—viz., (1) the line; (2) the power station; (3) the rolling-stock.

Under the first of these come the trolley wire, the poles, span wires, or other devices used for supporting the trolley, the feed wire, and the track. With regard to the first, it was easily foreseen and early proved that the currents of large and varying volume, if returned to the generating station through the rails and earth, would cause considerable disturbances upon the neighbouring telephone lines using grounded circuits. In order to avoid this, a complete metallic circuit with two trolley wires, suspended side by side about 8in. apart, was constructed, and every effort was made to perfect a system built upon these lines. Very little trial showed the insurmountable difficulties, both electrical and mechanical, which such an arrangement introduced. In the first place the wires, supporting and insulating devices, etc., had to be made of double the weight of a single trolley line, and therefore required heavier span wires and larger and more objectionable poles. Again it was fonnd that without making the spans of the trolley wire exceedingly short, and therefore greatly increasing the number of poles, it was impossible to pull the trolley wire up tight enough to avoid contact between the positive and negative wires. Endless short circuits and accidents to the wiring, owing to its great weight and the impossibility of securely supporting it without the employment of cumbersome and inadmissable supports and insulators, soon made a return to the single trolley wire a necessity. The remedy for the interference with the telephones has been found in the adoption, in the case of the latter, of a complete metallic circuit.

It has been found that a trolley wire about ¼in. in diameter gives better results than any other size. On very many short roads, on which the number of cars operated is small, this is large enough to transmit the requisite amount of power without too great a loss in the line. Smaller wires were found liable to accidents from strains which this size can readily withstand, and a larger wire necessitates the use of objectionably heavy supporting and insulating devices, so that No. 0 B and S gauge has been adopted almost exclusively as a standard size for urban roads. This is drawn very hard in mile lengths, and wound with the utmost care upon very heavy reels. This careful winding of the trolley wires is of the first

importance, owing to the fact that any looseness causes kinks in the wire, which are only with great difficulty removed.

(To be continued.)

SOME EXPERIMENTAL INVESTIGATIONS OF ALTERNATE CURRENTS.*

BY ALEXANDER SIEMENS.

Most of the papers read before this Institution on the subject of alternate electric currents, and on apparatus employed for utilising them, have dealt principally with the theoretical side of the question, and undoubtedly have been extremely useful to constructors of alternate-current apparatus. Nevertheless, certain gaps in our knowledge obtruded themselves in practice, and the investigations and experiments which are described in the present communication were undertaken not so much to verify any particular theory as to increase our knowledge of useful facts.

For convenience of reference, these experiments are not described in chronological order, but they have been grouped together according to the subjects which they are intended to elucidate. Foremost among these is the loss of energy through the heating of iron by induction where alternate electric currents are employed—a subject which engaged the attention of Prof. Ewing and of Dr. J. Hopkinson six years ago, whose researches pointed out the direction in which further experiments should be made. It is well known that this loss is caused by the so-called Foucault currents and by hysteresis. The effect of the former is counteracted by laminating the core of a magnet either by building it up with wires of small diameter or with thin discs, according to the direction of the lines of induction.

A short consideration will show that the heat produced by Foucault currents can be calculated beforehand for a core of known construction and dimensions. Take the case of an iron wire, 1 cm. long, subjected to an induction parallel to its axis of B lines per one square centimetre of its section. Let r be the radius of the wire, and ρ the radius of a ring, of the width $d\rho$, concentric with the wire. In this ring currents will be produced in the same manner as in the secondary circuit of a transformer. The maximum induction passing through this ring is $N = \rho^2 \pi . B$. Hence the E.M.F. generated is $E = 4 n N \times 10^{-8} = 4 n \rho^2 \pi B 10^{-8}$ volts.

If c is the conductivity of the iron employed, the resistance of the ring is $R = \frac{1}{c} \times \frac{2 \pi \rho}{d \rho}$; consequently the waste of energy in this ring, expressed in watts, is

$$d W = \frac{E^2}{R} = 8 c \pi n^2 B^2 \rho^3 d \rho . 10^{-16}.$$

The total energy wasted in 1 cm. length of the wire is therefore

$$W = 2 c . \pi . n^2 . B^2 . r^4 . 10^{-16} \text{ watts.}$$

From this formula a cable has been calculated to indicate the waste of energy by Foucault currents in 1 cwt. of iron of the conductivity $c = 0{\cdot}102 \times 10^6$, when an alternate current of the frequency $n = 100$ complete periods per second was employed.

Induction. B	Diameter of Wire. ½ mm. Watts.	1 mm. Watts.	2 mm. Watts.	3 mm. Watts.
1,000	0·8	3·3	13·3	29·9
2,000	3·3	13·3	53·3	119·9
3,000	7·4	29·9	119·9	269·8
4,000	13·4	53·3	213·3	479·8
5,000	20·8	83·3	333·2	749·7
6,000	29·9	119·9	479·8	1,079·4

In order to determine the total loss of energy caused by the heating of the iron, experiments were made with a specially constructed "cable transformer."

This mode of constructing transformers has been foreshadowed by Dr. Werner von Siemens, who proposed in his patent No. 42 of 1886 to surround the primary and secondary circuits of a transformer with iron wire, but his experiments gave no satisfactory results. The subject was recently taken up again, and the present form of these transformers was suggested by Mr. Dieselhorst and Dr. Baur. The principal advantage which is claimed for this form of transformer is that it can be made by machinery in the same way as a submarine cable is made, the employment of manual labour in putting it together being entirely avoided.

A special machine has been designed and erected for completing such transformers in one operation, after the iron core has been prepared on an ordinary rope-stranding machine. Besides offering these facilities for manufacture, the peculiar shape of the cable transformer lends itself to a variety of useful applications. For instance, at the Crystal Palace Exhibition one of these transformers connects an alternate-current machine to a high-voltage transformer some distance away, raising the potential of the current at the same time from 80 volts to 2,500 volts. The transformer used for the experiments has a core of 900 soft iron wires, each 1 mm. in diameter by 6 metres long, twisted up in the form of a rope, and surrounded by two windings of copper wire, properly insulated, the one for high voltage and the other for low voltage. From the fact that the diameter of the transformer is very small compared to its length, it follows that the magnetic field, and consequently the induction in the iron core, is uniformly distributed, with the exception of a slight drop at either end.

The mean induction produced by passing an alternate current through the low-voltage circuit was measured by the difference of potential obtained in the high-voltage circuit while no current was passing through the latter. The temperature of the iron core was ascertained by measuring the increase in the electrical resistance of one of its wires, which had been insulated from the rest by a cotton covering. By actual comparison it was found that one of the wires near the periphery gave, within the limits of errors of observation, the same results as the central wire, so that the exact position of this "test wire" has no influence on the result; the heating of the cotton insulation can be neglected, as its mass is so very small compared with that of the iron.

Separate tests were made to determine the specific heat of the iron, which was found to be = 0·112, and the temperature coefficient for the electrical resistance of the test wire, which was equal to 0·0054. The current was kept on for a short time only, as it was desired in the first instance to determine the rate at which energy is converted into heat in such a transformer, and the rise in temperature after keeping the current on for s seconds can be calculated from the formula—

$$t_s = \frac{R_s - R_o}{{\cdot}0054 . R_o}.$$

R_o = electrical resistance before starting the current; R_s = electrical resistance after keeping the current on for s seconds.

During the time that the current passes, the test wire will lose a certain amount of heat by radiation and convection, although it is surrounded by all the other iron wires, which are heated in a similar manner. This loss can, however, easily be allowed for by plotting a "cooling curve" after the passage of the current has been stopped, with times as abscissæ and temperatures as ordinates. In this way the rise of temperature of the iron core per second was observed with an alternate current of 100 complete periods per second, varying in strength so as to produce a different induction for each observation.

Considering that the loss of energy caused by the heating of the iron is proportionate to its mass, to its specific heat, and to its rise of temperature per second, it was possible to plot a curve in which the maximum number of C.G.S. lines per square centimetre are the abscissæ, and the losses of energy are represented as ordinates calculated for the mass of 1 cwt. of soft iron wires 1 mm. in diameter.

It should be added that the abscissæ of curve 2, Diagram I., which embodies the results obtained, have been calculated from the measured volts, instead of from the calculated mean volts, which in sinoidal waves are = 0·9 measured volts. This was done as curve 2 was to be used for designing transformers where the measured volts only are used for calculation.

As this curve gives the losses caused by hysteresis and by Foucault currents, while the formula given above enables us to calculate the losses caused by the Foucault currents alone, we can determine the loss by hysteresis alone by a simple subtraction. All these results, it must be remembered, refer to 1 cwt. of soft iron, subdivided into wires of 1 mm. diameter, on which an alternate current is acting of a frequency of 100 complete periods per second, the type of apparatus used being a cable transformer. The following table shows the results:

Induction. B =	Losses of energy. Curve 2. Watts.	Foucault currents. Watts.	Hysteresis. Watts.
1,000	43·2	3·3	39·9
2,000	96·2	13·3	82·9
3,000	158·0	29·9	128·1
4,000	231·2	53·3	177·9
5,000	309·5	83·3	226·2
6,000	390·1	119·9	270·2

The losses caused by hysteresis are independent of the dimensions of the iron. This table enables us, therefore, together with the formula for the losses caused by Foucault currents, to predetermine the rate of the loss of energy in iron wire of any weight or dimensions when acted upon by an alternate current of a frequency equal to 100 complete periods per second. Similar experiments were made with alternate currents of a frequency of 66·6 complete period per second, and of a frequency of 133·3 complete periods per second, and the curves embodying the results are also shown on Diagram I.

It should be observed that the currents of 66·6 and of 100 complete periods were obtained from the same alternate-current machine (type W_1), which has a high self induction in the armature, and of which it has been ascertained experimentally that the waves of its current are sinoidal. The currents of 133 complete periods per second were produced by another type of machine (W_{11}) with a low self-induction and a very narrow field.

On Diagram II. the losses by hysteresis alone have been shown, derived from the curves of Diagram I. by deducting the losses caused by Foucault currents according to calculation. By way of comparison, Prof. Ewing's curve of losses caused by static hysteresis has been added. In this table the results obtained with alternate currents of 133·3 complete periods per second have been left out of consideration, on account of their being made with a different machine, as just explained.

The next point to be investigated is the change which an alteration of the frequency of the current will involve in the case of a transformer designed for a given voltage in its secondary circuit. If it is borne in mind that this voltage, apart from the constant factors, depend on the product n N (n denoting the frequency, and N the maximum number of lines of induction), it follows at once that in order to produce the same E.M.F. with a lower frequency, the number of lines of induction has to be increased in proportion, and *vice versâ*. In other words, if the

* Paper read before the Institution of Electrical Engineers, *February 11, 1892.*

same E.M.F. is to be produced in the secondary circuit of a given transformer, the product n N must be constant. This result can at once be applied to the formula, which gives the losses of energy caused by Foucault currents—

$$W = 2\,c\,\pi\,n^2\,B^2\,r^4\,10^{-16};$$

and as $N = r^2 . \pi . B$, the formula can be expressed—

$$W = \frac{2\,c}{\pi}\,(n\,N)^2\,10^{-16};$$

or, in other words, these losses are constant for the same transformer, whatever the frequency may be, as long as the E.M.F. of the secondary circuit remains the same.

A comparison of the curves for a frequency of 66·7 and of 100 complete periods per second on Diagram I. shows that the losses of energy for the same induction are practically proportional to the frequencies. The same curves show that this loss increases more rapidly than the number of lines of induction.

From this consideration, it follows that a transformer which has been designed to produce a certain E.M.F. in its secondary circuit with a given frequency cannot produce the same E.M.F. with a lower frequency without overheating, while it remains cooler when it is worked with a higher frequency. In other words, transformers built for low frequency require much material.

An experiment was made to ascertain the final temperatures of a 50-h.p. transformer worked with different frequencies, and after 10 hours' working the maximum temperature was found to be—for a frequency of 100 complete periods per second, 53deg. C. in the core, and 46deg. C. on the outside; for a frequency of 66 complete periods per second, 69deg. C. in the core, and 57deg. C. on the outside—a result which appears to bear out the above consideration.

What frequency is most advantageous can, however, not be settled by taking into account nothing but the heating of the transformers: it is quite evident that the construction of suitable generating apparatus plays as important a part; and the problem resolves itself into the commercial one, which combination of apparatus can be constructed most cheaply?

The question, what induction should be settled upon in designing a transformer, is rather a complex one, and it can only be solved by taking into consideration: 1st. The amount of material, iron and copper. 2nd. The drop of potential difference in the secondary circuit from no load to full load. 3rd. The efficiency of the apparatus. 4th. The heating of the apparatus.

In order to facilitate the investigations a series of transformers is compared which all have the same length of iron core, and the same number of turns of copper wire of the same diameter.

It is assumed that one of these transformers is designed for an induction B = 5,000, and that its output is such that the weights of the iron and of the copper used in its construction are equal to each other and to 1 cwt.; this may be called the normal transformer. If, now, another transformer of the same series, but with a lower induction, is to produce the same voltage, the section of the iron has to be increased proportionately: for instance, in the case of B = 2,500 it has to be doubled. The weight of the iron employed varies, in fact, inversely as the induction, and their relation can be represented by a rectangular hyperbola (curve 7). As we have assumed that the thickness of the copper wire and the number of its turns are to be the same in all these transformers, the weight of the copper will vary directly with the length of wire wound on the iron core, and this can be determined if the relationship between the length of periphery and the section of the iron core is known.

In the case of the sections of the cores being circles, or squares, or rectangles, with the same ratio between their length and width, the length of periphery varies as the square root of the section. As transformers are generally designed with cores of this kind, it may be accepted that the periphery of the iron core, and, consequently, the weight of copper to be employed, varies as the square root of the section of the iron core.

The weight of copper in the series of transformers under contemplation can therefore be represented by a curve (8), the ordinates of which are the square root of the ordinates of the curve giving the weight of iron for the corresponding inductions. From these two curves it appears that the weight of the iron increases very rapidly with decreasing induction, while the weight of copper increases at a slower rate.

(*To be continued.*)

ELECTRICITY APPLIED TO MINING—THEORY AND PRACTICE.

At the meeting, last week, of the North of England Institute of Mining and Mechanical Engineers, held in Newcastle, Mr. D. Selby Bigge read a paper on electrical engineering as applied to coal mining, with an account of the installation recently effected at one of the Earl of Durham's collieries.

Mr. Bigge, in the course of an exhaustive address, said the question of power transmission by means of electricity is by no means a new or untried one, and though, perhaps, little is known of the details as yet by the mining world in general, results have been obtained in actual practice which merit serious attention. Electricity has now been applied, and with great success, in mining work for haulage, pumping, drilling, coal-cutting, and other minor uses, and as in the case of electric lighting, electric power may now fairly be said to have passed out of its experimental stage, and to have become an accomplished fact. It is chiefly as a means for transmitting power to great distances with small loss along the line that electricity will be found to predominate over any other known form of power transmission, and as distance is usually a most important factor in mining operations underground, electricity in a large number of cases will be found to adapt itself admirably to the work required to be done. The advantages claimed may be tabulated as follows: 1. A very large increase in working efficiency over any other known form of power transmission. 2. Considerable reduction in capital expenditure, when compared with other systems, a reduction which becomes more and more apparent as the distance for the power to be transmitted increases. 3. Increased facility in running the cables when compared with the laying of air or hydraulic mains. 4. Very small loss in the cables through resistance or leakage to earth when compared with the waste on a compressed air system. 5. Smallness in size of the machinery, thus proving itself to be of a portable nature and easily manipulated. 6. Absence of heat from the machinery underground. 7. Great simplicity in working. 8. Small cost of maintenance. 9. Finally, the ease and speed with which the whole plant can be erected and set to work. The principal objections raised against the employment of electric power are the following: 1. Danger arising from sparking at the motor brushes and main switch underground. 2. The idea that electrical machinery is of too delicate a nature for use in mines. 3. Risk of fire from breaking of the main cables by falls of stone, derailed tubs, or other causes. Having dealt with the three objections raised the author proceeded to consider the general question of electric power by electricity. When power is transmitted from one place to another by means of a fluid, such as steam, air, or water, through pipes, the difficulty of predetermining the exact loss of power from friction in these pipes is very great; in fact it varies so much under different circumstances that the author believed that exact determination may be said to be impossible. So, also, the loss of power in the motors driven by fluids is equally undeterminable with any degree of accuracy, on account of the variations in efficiency caused by slight alterations in load or speed, or by leakage through the valves or packings. These difficulties in calculation do not present themselves with electrical transmission of power. The loss of power in the cables depends solely on the electrical resistance, which is a practically constant quantity, and the current passing through the cables, which can be estimated with great accuracy. Nor is the loss of power in the motors more difficult to estimate: first, with a given motor the losses can be calculated with almost any degree of accuracy, from its known resistance and electrical or magnetic qualities; and, secondly, since the experimental determination of the efficiency of dynamos and motors is so readily carried out, a very great number of actual efficiency tests have been taken, from which the efficiency of a given size of machine of any particular type or construction can be easily foretold. The calculation, therefore, of the power wasted in transmitting power by means of electricity is extremely simple, and the efficiencies of a plant can be readily foretold, and the results to be obtained guaranteed with perfect confidence. The author thought that it might be of interest if he took two typical cases, and presented the results of the calculations in such a way that the members of the institute could compare them with those obtained in practice by any other methods. Having done this, he said that an inspection of the two tables which he gave would prove to the members with what ease and at what a comparatively small cost power can be transmitted to considerable distances, and he, therefore, desired to draw attention to one or two of the conclusions which are arrived at from this fact. First, where there are two or more collieries under the same management within a comparatively short distance of one another at which power is required, he would urge the desirability of establishing one central station where plant would be installed of sufficient power to serve the several collieries. The advantages of this plan are clear. (*a*) Inasmuch as all the machinery will not be working to its full capacity at each of the collieries simultaneously, the actual power at the one central station will be less than the sum of the powers which would have to be installed at each separate position, and in addition to this the plant would be cheaper, because the price of machinery does not vary directly as its output. (*b*) The cost of maintenance of a few large dynamos and engines will be less than that of a greater number of small ones. (*c*) Greater efficiency is obtained by running the machinery more nearly at its full load, the percentage variations of power required being smaller, when a large number of motors are taking power from the one plant. (*d*) The cost of attendance on the generating plant will be enormously reduced, the same number of men being able to attend the one central station as would attend to each of the separate plants. The great saving in all these directions had been fully proved by actual practice in the large central stations supplying light and power in London and other large towns.

COMPANIES' MEETINGS.

NEWCASTLE AND DISTRICT ELECTRIC LIGHTING COMPANY.

The fifth annual meeting of this Company was held on M[illegible] at the offices of Messrs. Leadbitter and Harvey, We[illegible] Newcastle-on-Tyne. Mr. John D. Milburn, chairm[illegible] presided.

The report and accounts were presented as fo[illegible] are happy to state that the prospects of [illegible]

[illegible]1	6	9
15,312	19	6
4,142	8	4
[illegible]	7	[illegible]

satisfactory. The installations connected to the mains during the year are equal to 4,000 16-c.p. lamps, bringing the total up to about 11,000, and 206,017 units of electrical energy have been supplied. The Company maintains amicable relations with its consumers, and trusts the consumption may ere long increase to a sufficient extent to enable the Directors to recommend a reduction in the price of current. The gross earnings during the year amount to £1,860. 15s., and after making provision for depreciation account and reserve fund, and writing off £200 from formation expenses, your Directors are able to recommend a dividend at the rate of 2½ per cent. for the half-year ending December 31, which, together with the interim dividend paid in July last, makes the dividend 5 per cent. for the year. Colonel W. M. Angus and Mr. John B. Simpson retire by rotation, but are eligible, and offer themselves for re-election. The auditors, Messrs. Strachan, Hill, and Co., also offer themselves for re-election.

* Paper read befo.

February 11, 1892.

The **Chairman** said: In moving the adoption of the Directors' report, I ask permission to say a few words concerning the position and progress of our Company. I have to congratulate the Company upon the steady progress which has been made since its commencement. It is true we are as yet but a Liliputian enterprise, as compared with the growth of the gas company, but we have risen above the ground, and have ample reason to believe that we shall prosper. Our receipts during the financial year ending 31st December last have amounted to £4,796. 18s. 6d., as against nearly £220,000 of receipts by the gas company. We have no war with the gas company. The first time I had the honour of addressing you, I, on behalf of your Directors, intimated that the Newcastle and District Electric Lighting Company did not intend to enter into any insane competition with gas. We wished to supply an artistic, healthy, and exhilarating light at a higher price than gas. We have hitherto steadily pursued this policy with a fair share of prosperity for ourselves, and with the result that instead of doing harm to the gas company, its business has actually increased, and it is even now seeking a large amount of fresh capital to allow of extensions. We have, therefore, actually exhilarated the gas company, for the lighting of the city, whether by gas or by electricity, was never before so efficiently and so well done as at present. There is yet long life in the gas company, and when artificial lighting shall no longer be its strong point, it will have many other sources of revenue. In electricity, however, we represent the leading energy of this age, and your Directors will not be content until our Company grows and expands, until it is doing a fair share of the lighting of this city. Not only should we occupy ourselves with the production of energy for lighting purposes, but we should cultivate its use for motive power. I do not think we shall have many years to wait before tramways are principally worked by electricity. I am convinced that, as soon as we shall be able to show the directors of our local tramways any advantage in the use of electricity — especially on such horse-killing places as Westgate-hill — they will not be slow to adopt it. Electric motors will also be found useful for the propulsion of machinery in its manifold uses, and I think something more might be done by us to encourage the adoption of electrical motors. The use of our plant, or a large proportion thereof, during the daytime would considerably reduce our cost of production, and render remunerative to the Company the day hours as well as the night hours, upon which we have chiefly to depend for our revenue. Your Directors are fully alive to the interests of the public, and so soon as the business of the Company shall have attained sufficient volume, and the cost of production be reduced, they will recommend a reduction in price, and so bring the use of electricity into still greater popularity. No one who has once used the electric light has any inclination to go back to gas lighting. It would be more difficult to pervert a good Mahomedan than to wean back again a user of the electric light to gas, notwithstanding the higher price. Its advantages, comfort, healthiness, and cleanliness, are fully recognised and appreciated. If to these merits, however, comparative cheapness can be added, the two electric lighting companies of the city would very speedily open up "fresh woods and pastures new." That there is a great future before us, your Directors would fain hope. Coming to the results of the recent year's work, the shareholders may be interested to know that during the past year lamps equal to about 4,000 16-c.p. lights were connected to the Company's mains, and during the same time, 15,610 yards of cable have been laid, and 2,430 yards of main and branch piping. The 6in. main pipe which at the commencement of the Company's operations was laid in Fourth Banks, is now filled up with cable, and in view of the demands which are being being received for supply of current, it has been found necessary to commence laying another 6in. main.

Mr. J. R. Holliday seconded the adoption of the report.

The report was adopted, and the dividend declared.

The retiring Directors and the Auditors were re-elected.

A vote of thanks to the Chairman terminated the meeting.

COMPANIES' REPORTS.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY.

Directors: S. Wm. Silver, Esq., chairman; Neil Bannatyne, Esq.; Abraham Scott, Esq.; Matthew Gray, Esq., managing director; Robert Henderson, Esq.; the Hon. Henry Marsham; A. Weston Jarvis, Esq., M.P.

Report of the Directors for the year ending December 31, 1891, to be presented at the twenty-eighth ordinary general meeting of the shareholders, to be held at the Cannon-street Hotel, on Tuesday, February 23, at 12 noon.

The annexed accounts show the net profit for the past year to be £79,102. 8s. Adding £39,970. 17s. 10d. brought forward, and deducting £20,800 interim dividend paid in July, there remains a disposable balance of £98,273. 5s. 10d. The Directors have added £25,000 of this balance to the reserve fund (raising it to £325,000), and recommend the distribution of a dividend of 10s. and a bonus of 5s. per share, free of income tax, amounting to £31,200, making, with the interim dividend, a total payment for the year of 12½ per cent., and leaving £42,073. 5s. 10d. to be carried forward. The increase in the sales of the Company's general manufactures continues. The cable department has been fairly well employed. More than 1,600 miles of cable have now been manufactured for the South American Cable Company; and it is expected that the

whole length contracted for will be made and laid by Midsummer. The efficiency of the works and machinery has been fully maintained. Mr. Scott and Mr. Jarvis, the directors retiring by rotation, offer themselves for re-election. Mr. Weise is re-eligible as auditor.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.

Directors: The Right Hon. Lord Suffield, K.C.B., Edmund Boulnois, Esq., M.P., W. Hayes Fisher, Esq., M.P., Sir Douglas Galton, K.C.B., F.R.S., M.Inst.E.E., J. Browne Martin, Esq., James Heslop Powell, Esq., Roger W. Wallace, Esq. General manager: Captain Edmund I. Bax. Engineer-in-charge: Prof. Alex. B. W. Kennedy, F.R.S., M.Inst.C.E. Secretary: Frank Iago, Esq.

Report of the Directors to be presented to the shareholders at the ordinary general meeting to be held at the Westminster Palace Hotel, S.W., on Wednesday, the 24th inst., at 11 a.m.

In submitting their report and accounts for the year 1891 the Board of Directors are pleased to state that the business of the Corporation is making satisfactory progress, for although two of the stations were not in work until the end of March, and one is still in the builder's hands, the accounts of the past year show a considerable profit upon the working, after making provision for bad and doubtful debts, allowing a fair amount for depreciation, and writing off a proportion of the preliminary expenses and suspense account. In their report last year, the Board stated that current was being supplied to the equivalent of about 12,000 lamps of 8 c.p. At the present time current is being supplied to 67,500 lamps of 8 c.p., while applications are signed for a further 5,083 lamps of 8 c.p. The application to Parliament for permission to supply the northern district of Westminster was successful, the Royal assent to the Bill having been given on July 3, 1891. Mains have now been laid in all the scheduled streets throughout the area of supply, as also in every other street where the expenditure has been justified by the demand for current, both in the original and additional order. The total length of roadway along which mains have been laid up to the present date is about 31 miles. This includes a total of about 123 miles of ways, along which 89 miles of copper have been drawn. Your Directors have every reason to believe that the Corporation's supply, which has so successfully been given to the Houses of Parliament, will be extended to other Government offices at no very distant date. Two of the stations of the Corporation which had not been finished at the date of the last general meeting (the Mayfair station in Davies-street and the Belgravia station in Eccleston-place) commenced to supply current in March last, and, together with the Westminster station in Millbank-street, have since been constantly at work. The reports from consumers and others as to the quality of the light supplied have been very gratifying, and the increase in the number of applications for current received may no doubt be ascribed to this fact. As shown in the accompanying accounts the net revenue of the Corporation for the past year is £3,160. 4s. 3d., and this sum the Board consider should be carried forward. The balance of the authorised share capital—viz., £85,235 in 17,047 shares of £5 each—was, in accordance with the resolution of the shareholders at the general meeting in February last, issued at par, and was duly subscribed for; many of the original shareholders increased their holdings, and a number of the consumers on the Corporation's circuits invested in the shares. The whole of the authorised capital has now been subscribed and paid up in full, and it is very satisfactory to the Board to be able to state that there is not a single unpaid call. The Directors have not made any public issue of the debenture capital, for which powers are given in the articles of association, but have allotted £29,400 in 5 per cent. mortgage debentures to applicants, many of whom had applied for ordinary shares of the Corporation. The auditors, Messrs. Cooper Brothers and Co., retire, and, being eligible, offer themselves for re-election.

BUSINESS NOTES.

West India and Panama Telegraph Company.—The receipts for the half-month ended Feb 15 were £2,655, against £3,236.

Warrants for Interest at the rate of 6 per cent. per annum on the preference shares of the Western Counties and South Wales Telephone Company, Limited, for the half-year ended December 31st last, have been posted.

City and South London Railway.—The receipts for the week ending 14th February were £881, against £728 for the corresponding period of last year, showing an increase of £153. As compared with the week ending February 7th, last week's receipts show an increase of £57.

Birmingham Electric Supply Company. —We notice that 5,625 shares of £5 each in this Company, being the balance unissued, are now being offered in Birmingham at par. Five shillings is to be paid on application and 15s. on allotment. Any subsequent calls are not to be for more than £1 per share at three months' notice, and at intervals of not less than three months. Existing shareholders will have priority of allotment.

PROVISIONAL PATENTS, 1892.

February 8.

2365. **Improvements in electrical communicating apparatus for mining and other works.** Alexander Ferrie Mabon, 87, St. Vincent-street, Glasgow.

2393. **Improved method of and appliances for using electricity as a medicinal agent.** William Grigg, 11, Furnival-street, Holborn, London.

2396. **An improved microphone or transmitter.** John Henry Kindle, 9, Warwick-court, Gray's Inn, London.

2397. **Electric fire alarm.** Ernest Dyer Wise, 69, Lever-street, Goswell-road, London.

2401. **Improvements in incandescent lamps.** Perrin Grant, Monument-chambers, King William-street, London.

2417. **Apparatus to gather and store electricity or energy from water, the earth, or from the atmosphere.** Richard Joseph Crowley, Queenstown, Cork, Ireland.

February 9.

2438. **Improvements in relays for submarine telegraphy.** Gaspare Sacco, 7, Martin's-lane, Cannon-street, London.

2448. **Improvements in and connected with the arrangement and operation of relays in telegraphic systems.** William Frederick Wentz, 70, Market-street, Manchester. (Complete specification.)

2486. **Improved composition of matter suitable for use in the manufacture of journal bearings packings, projectile rings, commutator brushes, and various other articles where surfaces come into frictional contact, and for conductors of electricity.** Philip Henry Holmes, 47, Lincoln's-inn-fields, London. (Complete specification.)

2488. **Electric lighting system.** Sylvanus Lander Trippe, 33, Chancery-lane, London. (Complete specification.)

2497. **Improvements in magneto-electric machines.** John Hunt, 55, Chancery-lane, London. (Complete specification.)

2540. **Improvements in the arrangements of conductors for electric traction.** John Edward Waller, 47, Lincoln's-inn-fields, London.

2541. **Apparatus for and method of recording the time during which telephones, phonographs, and other instruments or machines are in use or at work.** Bernhard Heinrich Carl Bogler, High Holborn, London. (Karl Strecker, Germany.)

2544. **Improvements in electrical motors.** Alfred Julius Boult, 323, High Holborn, London. (William Joseph Still, Canada.) (Complete specification.)

February 10.

2588. **Improvements in telephonic switching apparatus.** Ernest Frank Furtado and Charles Benjamin Oakley, 48, St. Paul's-road, Camden Town, London.

2618. **Improvements in electrometers.** Paul Bary, 28, Southampton-buildings, London.

2621. **An improved telephone combination.** Sir Charles Stewart Forbes, Bart., 21, Finsbury-pavement, London.

February 11.

2646. **Improvements in telephonic transmitters.** Luis Larranaga, 36, Chancery-lane, London.

2652. **Improved regulator for voltaic arc lamps.** Frédéric Klostermann, 3, Tokenhouse-buildings, London.

2653. **Improvements connected with electrically operated coin-freed apparatus.** Herbert Edwin Langley, 166, *Fleet-street, London.*

2690. **Improvements in electric arc lamps.** Henry Tipping, 55, Chancery-lane, London.

2722. **Improvements in electric switches.** Alfred Lyster Shepard, 45, Southampton-buildings, London.

2724. **Improvements in electro-therapeutical apparatus.** Armin Grimm, 45, Southampton-buildings, London. (Complete specification.)

2727 **Improvements in telephone receivers.** Oliver Imray, 28, Southampton-buildings, London. (Ferdinand Gross, Canada.)

2733. **Improvements in and relating to the driving and controlling of riveting, shearing, punching, and other machines by electricity.** Albert Piat, 46, Lincoln's-inn-fields, London.

February 12.

2743. **The application of electricity to a scientific puzzle.** Algernon Sidney Field, Aberdeen Lodge, Worple-road, Wimbledon.

2744. **Improvements in telephonic instruments.** Berthold Hoffman, 70, Market-street, Manchester. (Complete specification)

2748. **Electro-heliograph suitable for interastral communication.** Richard Joseph Crowley, Queenstown, co. Cork, Ireland.

2762. **Improvements in or relating to electrical signal apparatus for indicating the position of railway switches or points.** William Phillips Thompson, 6, Lord-street, Liverpool. (Paul Schwenke, Germany.) (Complete specification.)

2775. **Improvements in ozonising or electrifying atmospheric air or other gases.** Richard Arthur Prior Taunton, 11 Furnival-street, Holborn. London.

2784. **Improvements in or relating to sockets and switches for incandescent lamps.** John Clayton Mewburn, 55, Chancery-lane, London. (David H. Piffard, United States.)

2785. **Improvements in incandescent electric lamps.** John Clayton Mewburn, 55, Chancery-lane, London. (David H. Piffard, United States.

2791. **An improved time-registering device for electric currents.** Walter Cobb, jun., and William D. Wilder, 55, Chancery-lane, London.

February 13.

2831. **Improvements in apparatus for the driving of chronometric balances and pendulums for electricity meters.** Joseph Oulton, and Joseph Edmondson, Bank-chambers, Waterhouse-street, Halifax.

2849. **Improvements in and relating to electrical devices for operating railway points.** William Phillips Thompson, 6, Lord-street, Liverpool. (Emile Klatte, Germany.)

NOTES.

Warsaw is to have an electric light station.

Llandudno will shortly want a new gasholder. Why not a dynamo-room?

Mansfield.—The price for public gas lamps is nearly £4 a year in Mansfield.

Leeds.—The Board of Trade have approved of the extension of the Leeds electric lighting order until April 3rd, 1892.

Deputation from the City.—A section of the Commissioners of Sewers will visit the Crystal Palace Exhibition on Tuesday.

Lundy Island.—Another wreck has been totally lost at Lundy, to a large extent from want of telegraphic communication to the mainland.

Dundee is to have a new post office. All new large post offices are now lighted electrically, and Dundee will, we may suppose, be no exception to this rule.

Liverpool Tramways.—The Liverpool Tramway Company is extending a mile of line, at £2,200 a mile for the permanent way, single line, with passing-places.

The Manchester Co-operative Stores in Balloon-street are lighted by incandescent lamps, the current for which is generated by a Parsons steam turbine plant.

Coventry.—Mr. West will bring in a motion at the next meeting of the Coventry Town Council that a deputation be appointed to visit the Crystal Palace Exhibition.

Electric Heaters.—The use of electric heaters in the tramcars in those cases where they are used, are found to make no perceptible difference in the current consumption.

Edinburgh Tramways. — The Portobello Local Authority have determined to petition against the Edinburgh Tramway Bill, which is being promoted by the tramway company.

Sir William Thomson's Title.—In Tuesday's *Gazette* the titles of the new peers are given. That of Sir William Thomson is "Baron Kelvin, of Largs, in the county of Ayr."

Tesla's Experiments.—Mr. J. E. H. Gordon will contribute an article on Mr. Tesla's experiments to the March number of the *Nineteenth Century*.

Registered Electrical Contractors.—"Lux," in the *Manchester Guardian*, suggests that the Council should only allow competent and registered electrical contractors to fit up installations for the city electric system.

Killed by Lightning.—An unusual occurrence happened at Dartmoor last Saturday, when a healthy lad of 14, named William French, was found dead in bed, having been struck by lightning while asleep. This is almost a unique accident.

Barnet.—The Barnet Local Board are complaining of the bad state of the gas lighting, and have instructed the clerk to write to the gas company. The progressive section of the Board should send a deputation to see the lighting of Fareham.

Government and Coast Telegraphs.—Mr. Penrose Fitzgerald has given notice that on March 16 he should move a resolution, on going into Committee of Supply, with reference to telegraphic communication between light-houses and lifeboat stations.

King's College.—The Siemens Laboratory at King's College, London, was formally opened by Sir W. Thomson on Friday last. This laboratory has been equipped and presented to the college by Lady Siemens, in memory of the late Sir William Siemens.

New Journal.—We have received *Sciences et Commerce*, a new French journal devoted to applications of science, in which electricity bears a large part. The London agent is Geo. Street and Co.; the price 60c.; fortnightly. It makes a handsome appearance.

Office Manual.—Young engineers going into business will find the "Universal Office Manual" (Oxborrow and Co., 17, Victoria-street, S.W., 5s.) of use to them for guiding them in the necessary details of commerce, book-keeping, and finance, into which it goes very fully.

Cork Tramways.—The Board of Works held a public enquiry in Cork with reference to the proposed tramways on Monday. The cars are to carry 24 passengers, and will weigh 28cwt. each. The city engineer objected to the use of overhead wires if electric traction were to be used.

Acid Fumes.—The discomfort from the acid fumes from the batteries in the Birmingham electric cars is causing much discussion. Coughing is said to be frequent from the acid spray emitted. There should be no difficulty in having sufficient air-holes under the seats to prevent discomfort from this cause.

Portsmouth.—The estimated cost of the plant for Portsmouth on the high-tension scheme recommended by Prof. Garnett is £38,285, while the annual receipts from private and public lighting are expected to reach £10,800. The expenditure, including interest on £40,000, at 3½ per cent., is estimated at £7,572.

Purchase of the Telephone System. — Dr. Cameron has given notice to call attention, on the Civil Service Estimates, to the relations between the Postal Telegraph Department and the telephone system. He will bring forward a motion in favour of the acquirement of the telephone system by the Post Office.

Electric Mains in Paris.—One of the Paris electric light companies is to spend 1,300,000f. in altering its underground mains and laying mains in two new streets. The *Bulletin International* remarks that it is said in Paris the cost of laying a metre of underground mains comes to 90f., and after altering and repair to 150f.

Book Received. — We have received a copy of "Modern Practice of the Electric Telegraph—a Technical Hand-book for Electricians, Managers, and Operators," with 185 illustrations, by Franklin Leonard Pope, fourteenth edition, rewritten and enlarged. (New York: Van Nostrand; and London: Sampson Low and Co.)

City Meat Market.—The Streets Committee of the Commissioners of Sewers recommend that the Central Markets Committee be informed that there are contracts for lighting the public streets of the City, and owners can arrange for private lighting, but there is nothing to prevent the meat markets producing their own light if they so desire.

Switch Catalogue.—We are in receipt of the catalogue of Mr. A. P. Lundberg, of Bradbury-street, Kingsland, whose switches are well known, being amongst those earliest in the field for small practical switches. Some new kinds of switches and wall sockets are shown, besides good types of main switches and the original "Pioneer" switch.

Saving Power.—The current in driving electric cars is often far more greatly increased by dust between rails and wheels than most persons would be inclined to suspect. The best way to reduce this is by having periodical washing by salt water, which has been found in practice by American

roads to reduce the consumption 30 per cent.—from 900 to 600 amperes.

St. Helens.—The Local Government Board have written to the St. Helens town clerk (Mr. W. J. Jeeves) sanctioning the borrowing of £1,500 for electric lighting of the Town Hall. For the accommodation of the dynamos the Water Committee's storage is being removed from the Town Hall yard to a building specially erected for their accommodation.

Flying Machine.—We stated last week that the flying machine, constructed upon the model of the flying fox, was made by Messrs. Shaw and Sons, of Coventry. Mr. Albion T. Snell, engineer to the General Electric Traction Company, writes to inform us that the machine and motor have been made by that company to designs by Major Moore; the wings only have been made by Messrs. Shaw.

Electric Fire Engine.—The Kummer electric fire engine, made by Messrs. Kummer, of Dresden, uses 50 amperes at 100 volts, or 75 amperes at 65 volts, being 500 watts. The pump throws 500 litres of water per second, and, with a nozzle of 18 mm. diameter, gives a height of throw of 35 to 40 metres. It weighs 2¼ tons, and costs only about half that of an ordinary steam fire engine.

Electric Bells.—The new (ninth) edition of the General Electric Company's catalogue of electric bells has just been issued. Besides bells, pushes, commutators, and all necessary fittings of many and varied kinds for electric bells, it gives illustrations of some neat and cheap sets of students' experimental sets for studying frictional and current electricity, which should prove of use to schools.

Resistance of Cobalt.—Prof. C. G. Nott, in a paper to the *Proceedings* of the Royal Society of Edinburgh, comes to the conclusion experimentally that between the temperatures of 400deg. C. and 700deg. C., the resistance of a cobalt strip increases on an average at a rate nearly twice as great as the average rate of increase between 0deg. and 300deg. C. He also investigates the thermo-electric position of cobalt.

Electrocution at Abattoirs.—The abattoir (public slaughter-house) at Aberdeen is about to be lighted by electricity. In the event of the use in this direction of an alternating-current dynamo, a trial will be made of its capabilities for slaughtering cattle. It is anticipated that this application may become general if experience should prove that it has no detrimental effect upon the quality of the meat.

Chicago Congress.—The work of organising the congress in Division E, Electrical Engineering, during the Chicago Exhibition, is assigned to the American Institute of Electrical Engineers. Suggestions are invited. Papers will be admitted from engineers all over the world and in any language (to be translated). Copies or abstracts will be printed. The work of organising is to be at once undertaken.

Blackpool.—The Blackpool Corporation are going in for an extended scheme of electric lighting. This will include the extension of the present lights along the promenade to the extreme end of South Shore, and as far as The Glynn Inn, North Shore. It is also proposed to illuminate several of the principal thoroughfares with the electric light, and likewise supply shops and places of business requiring it.

Croydon.—The new municipal buildings at Croydon are to be wired for electric light, so that if no private company undertook the work the Corporation might eventually supply themselves with electric light. The Mayor considered the Council had nothing to lose by a little delay. It is suggested that an electric installation might be established at the Croydon pumping station for lighting the Town Hall.

Society of Arts.—Prof. William Robinson, of Nottingham, is about to deliver a course of four Cantor lectures on the "Uses of Petroleum in Prime Movers," before the Society of Arts, on successive Monday evenings, the first lecture being on Monday next, 29th inst. After dealing with the subject generally, the lecturer will treat of petroleum oil engines, oil gas, and gaseous fuel for steam boilers.

Electric Railways Deferred.—At a meeting of the Illinois central board of directors, in Chicago, the project of using electricity as a motive power for trains was abandoned. The special committee of directors which has been investigating the matter reported that, so far as they could ascertain, the development of electricity as a motive power has not yet progressed far enough to warrant the company in attempting to use it in place of steam.

Telephone in the Army.—At the Royal United Service Institution last Friday Major Beresford, R.E., lectured on "The Telephone at Home and in the Field." The great requirements were an improved telephone and a wider knowledge of shorthand. Telephones could be employed for coast defence, artillery, submarine mining, rifle and artillery ranges, communication in the field, intercommunication in camp, and for outpost duty.

Electric Float.—The *Daily Graphic* on Monday describes and illustrates an invention by Mr. J. Hibberd, of Cardiff, for connecting the shore with a ship in case of shipwreck. It consists of a pointed float of sheet iron, with electric motor and propeller ballasted with sand, which is discharged when the float strikes the ship, and the float rises to the surface, allowing connection by cables to be made. An incandescent lamp is used as guide.

Liverpool.—At the meeting of the Liverpool Watch Committee on Monday, the clauses setting forth the terms agreed upon by the committee and the Liverpool Electric Supply Company last week were approved of. The Corporation will have the power, if the agreement be endorsed by the Council, to purchase the undertaking of the company as a going concern at any time after the 30th of June, 1898, upon giving 12 months' notice of their intention.

Bury.—An expert in engineering and electric lighting has visited Bury (Lancashire) and made an inspection of the various weirs and waterfalls on the two local rivers, the Irwell and Roch, with the view of advising upon their capabilities for supplying power to drive the dynamos in order to furnish the town with electricity for lighting purposes. It is understood that owing to the very irregular flow of water in the two rivers named that such a scheme will not be recommended.

Telegraph to Gilgit.—Mr. Olpherts, the officer of the Telegraph Department who has been examining the route for the extension of the wire through to Gilgit, has returned to Srinagar. He has seen the passes at their worst and can now judge of the chances of the telegraph being kept up even in the severest snowstorms. He will probably, says the *Indian Engineer*, be summoned to Calcutta to consult with Mr. Brooke, director-general of telegraphs, regarding the construction of the line next summer.

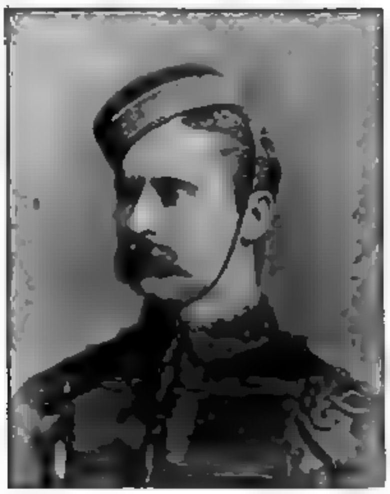
Spurgeon's Orphanage.—An action has been brought by the authorities of Spurgeon's Stockwell Orphanage against the City and South London Electric Railway Company, to restrain the company from causing vibration. The defendants pleaded statutory right. Mr. Justice Kekewich on Tuesday said the defendants were right in law, but as, according to the report of the engineer, they had not at first done all that was possible to mitigate the nuisance,

A. M. STUART.

ROBERT HAMMOND.

RAYNSFORD JACKSON.

COL. DU PLAT TAYLOR.



CAPT. HOLDEN.

they must pay the costs of the action up to the end of 1891, and £50 damages.

Fire at Messrs. Hodges and Todd.—Referring to the fire which occurred last Thursday in Verulam-street, which completely destroyed the works of Messrs. Hodges and Todd, we are pleased to learn the fire did not originate on their premises, as reported by many of the daily papers, but commenced on adjoining premises. They have secured new premises at 19, Kirby-street, Hatton-garden, and the work of fitting up is being rapidly pushed forward, and in a few days they hope to be able to execute all their orders.

Mutual Telephone Company, Limited. — The February list of subscribers to this company's Manchester exchange contains over 1,000 names. This is the result of exactly 12 months' working, the exchange having been opened on February 28, 1891, with 68 subscribers. Counting the orders on hand still to be executed, irrespective of those daily received, the Mutual Company's exchange has already attained greater proportions than that of the National Company in the same town. The company has also 500 spare metallic circuits erected and a number of private lines.

Pamphlets Received.—We are pleased to acknowledge some very interesting electrical pamphlets and reprints forwarded to us by Prof. W. E. Ayrton, F.R.S., President I.E.E. These comprise papers on "Quadrant Electrometers," from the *Proceedings* of the Royal Society, by Prof. Ayrton, Prof. Perry, and Dr. W. E Sumpner; on "The Construction of Non-Inductive Resistances," from the *Phil. Mag.*, by Prof. Ayrton and Mr. T. Mather; on "Alternate Current and Potential Difference Analogies in the Methods of Measuring Power," from the *Phil. Mag.*, by Prof. Ayrton and Dr. Sumpner.

Telephone Bills.—The town clerk of the Gravesend Town Council, at the special meeting last week, reported objectionable features in these Bills, in which the National Telephone Company, Limited, more especially sought very unusual powers, both as regards public and private property, for the whole of England, and this without offering to bind themselves to supply communication or to limit its price or the rate of dividends they might divide. The committee recommend the Council to petition against both Bills, on the understanding that the opposition be undertaken through the Municipal Corporations Association, at a cost not exceeding £20.

Islington Electric Railway.—The parliamentary estimates of the cost of extending the City and South London Railway to Islington have been prepared by Mr. J. H. Greathead, the engineer to the company. The length of this extension is given in these estimates as two miles five furlongs three chains, and the total cost is set down at £706,633. Of this sum, £330,540 will, it is estimated, be spent in tunnelling, £211,000 upon the acquisition of land and buildings, £81,600 upon stations, and £13,500 for the subway for foot passengers to and from Fish-street-hill. The laying of the permanent way will absorb £15,844, of which £2,500 will be for sidings, whilst for contingencies a sum amounting to £54,149 is allowed.

Railway Station Indicator.—Considerable discussion has been aroused in the daily papers with reference to the statement by the President of the Board of Trade that he was not aware of any mechanism by which the indication of the names of stations could be given in the carriages themselves. One suggestion is that no mechanism is necessary, but that the porters should slip at each stopping, place cards with the name of the station into slots at the windows. This is simple but clumsy, and could hardly be found to work in practice. We may mention that in the Crystal Palace Exhibition, South Gallery, is an electric railway station indicator, to be worked from the guard's van, shown by Messrs. Thatcher and Devereux, 15, Chivalry-road, Battersea.

Shiplighting.—A preliminary trial of the dynamos and electrical fittings of the cruiser "Edgar" was made at Keyham on Tuesday, but was not completed. The "Edgar" has been supplied with three dynamo-engines of the Siemens type, one of which is to be used under ordinary circumstances, whilst the other two—which are protected from shells by the ship's engines—are intended for use in action. Each of the three engines is capable of developing 400 amperes at 80 volts, and is intended to light the ship throughout, besides supplying the necessary force for working four search-lights of 2,500 c.p. The "Edgar" is lighted internally by 400 incandescent lights of 16 c.p. Sunbeam and yardarm lights will be supplied for special purposes such as coaling. The bunkers and magazines are also lighted by electricity.

Arc v. Incandescent.—The proposal having been made to use 150-c.p. incandescent lamps for street lighting at Portsmouth, Mr. Jas. Blake, managing director of the Fareham Company, writes to the Portsmouth paper to point out that while two 150-c.p. lamps would take nearly 4 h.p., a 1,200-c.p. arc can be produced for ½ h.p., or, allowing 50 per cent. for globe absorption, say, 600 c.p., giving a difference in favour of arcs of eight to one. In maintenance, at three renewals a year, the eight incandescents would cost 60s., while his experience with arc lamps shows that 40s. would not be exceeded for consumption of carbons. He asks the Portsmouth Town Council to send a deputation to visit their small neighbour, when he promises to show them "a mile and a half of the best-lighted streets in this country."

Goole.—At the monthly meeting of the Goole Local Board, held last week, Mr. Hind said that he wished to move an amendment in respect of that portion of the minutes relating to laying of electric cables. He wished to move that permission be given to lay down electric cables, subject to the restrictions that an agreement be entered into between the promoters of the electric company and the Local Board, giving them the power, and that power should be given to the Board to at any time purchase the electric works from the applicants, at a price to be fixed by the valuers, in the usual way. The reason he moved this was that it would be necessary, in case the Local Board took the gas lighting over, they should also have the electric lighting. This was carried, with an addition that the permission be given subject to such by-laws and conditions as the Board may hereafter make.

Systems of Traction.—An American engineer is at present in England wanting English capitalists to take up his system of open conduit for electric traction. Meantime, Messrs. Siemens's system, as used at Budapest, is being taken up in America by a powerful syndicate, who are going to lay six miles at once. Messrs. Manville and Waller, of Victoria-street, have an excellent open-conduit system which they are willing to instal at once on orders being received. We hear nothing further awhile about Mr. Gordon's closed-conduit system. Possibly something practical may come of this. Mr. Lineff is hardly doing as much as was expected of him. Accumulator traction is being quietly organised for large strokes of business, and the Thomson-Houston Company has shown us the way in overhead work, and may be expected to develop other work vigorously. Mr. Holroyd Smith is reported busy on his experimental line, and other schemes are in the wind. Surely electric tramway work in England must shortly go ahead with all this stirring enterprise beneath the surface.

Boiling Magnets.—The influence of steam on magnets is the subject of an interesting note in the *Schweizerische Bauzeitung*, in which reference is made to the researches of Strouhal and Barus. These have shown that with long-continued heating in steam, magnets lose from 28 to 67 per cent. of their power. If, after this, the magnets are remagnetised and again exposed to the action of steam, only a very slight loss of magnetic power is found to take place. The experiments which have been made would seem to warrant the conclusion also, that after such treatment a magnet is less liable to deterioration from mechanical vibration as well as heat. In one of the experiments a short magnet was boiled in water for four hours. It was then magnetised and held in an atmosphere of steam for two hours more, after which its magnetic moment was measured. It was then subjected to 50 blows from a piece of wood, both transversely and longitudinally. Again measuring its magnetic moment showed a loss of $\frac{1}{900}$, and on repeating the hammering with the wooden bar the loss was $\frac{1}{400}$ of the original moment. In view of this, repeated steaming and magnetising is recommended as a good means of securing permanent magnetism in pieces of hard steel.

A New Use for the Microphone.—Prof. D. E. Hughes, F.R.S., writes to us from 69, Pall mall, S.W., yesterday: "Having been engaged for many years experimenting with my microphone for the detection of sounds too feeble for the unaided human ear, I am pleased to notice by the following paragraph in the *Daily Telegraph* of February 25 that it has been successfully applied in St. Petersburg to the saving of human life." The paragraph says: "Some particulars of a remarkable case of revival from apparent death have come to hand from St. Petersburg. A lady who had been suffering from a violent nervous attack sank into a state of syncope, and after a time ceased, as it seemed, to breathe. The doctor who was attending her certified that death had resulted from paralysis of the heart. For some reason which is not explained another medical man, Dr. Loukhmanow, saw the body, and having been informed that the lady had suffered from attacks of hysteria and catalepsy, thought it worth while to make a thorough examination. After trying various other means he applied the microphone to the region of the heart, and was enabled by this instrument to hear a faint beating, which proved that life was not extinct. Everything was done to resuscitate the patient, who, shortly afterwards, recovered consciousness."

H.M.S. "Ramillies."—The forthcoming launch of the new first-class twin-screw battleship H.M.S. "Ramillies" will take place at Clyde Bank on Tuesday, March 1st, at 1.30 p.m. Electricity has played a considerable part in building the ship, the temporary installation being under the charge of Mr. John Young. The ship's sides were bored by electrical drillers, made especially for the occasion by Messrs. McWhirter and Ferguson, Faraday Electrical Works, Govan, under the superintendence of Mr. A. A. Stewart, chief engineer, Clyde Bank Shipyard. The belt deck and other decks were also drilled by three other electrical drillers. The diameter of holes in the ship's side were 5½in., 8in. of teak being bored before penetrating the two steel plates, each 3¼in. thick. Electric light is, of course, used—at the large cutters six 400-c.p. Sunbeam lamps on deck, and six below in the stokeholes and engine-rooms. There are also 100 16-c.p. incandescent lamps, and another 200 are being fitted up for present lighting in magazines, shell, store, and ammunition rooms, passages, and other places throughout the ship. The current is now supplied from a Crompton dynamo, working at 110 volts, driven off shafting in connection with shipyard machinery, a main cable, $^{19}/_{14}$, being employed. After launching, the installation will be supplied by a Robey portable engine and boiler combined, and a Paterson and Cooper dynamo will be employed on deck for temporary lighting. The battleship is to be christened by her Grace the Duchess of Abercorn, and a large concourse of spectators and visitors is expected.

Church by Telephone.—Several instances have lately been recorded of the transmission of church services by telephone. One of the most successful of these seems to have been that carried out the other Sunday—from Christ Church, Birmingham, to Derby, 40 miles away. An "extra-parochial" congregation of 17 persons assembled to take part in the telephonic service arranged for them by Mr. Ollerenshaw, the district inspector of the National Telephone Company. At 10.30 a.m. they seated themselves before the table, on which lay a number of ordinary Bell receivers. The bell was tolling loud and clear, and was audible over the room. Then it ceased, and nothing was audible except the broken murmur of footsteps and the opening of books. A soft note was heard through the murmur, then bursting into the full power of the organ, and again subsiding. Next a voice, which soon recited the familiar "Dearly beloved brethren," every word being distinctly articulated. The responses, the psalms, and *Jubilate* were all so realistic as to render it difficult for the listeners to remember they were not in church. The Birmingham church is the only one in the Midlands yet fitted with telephone. The arrangements are somewhat complicated, and include transmitting microphones in the choir and belfry, and before the pulpit, lectern, and reading-desk. The churchwarden has a switchboard in his pew, and his duty is to keep the proper transmitter in circuit. Already "church" is supplied regularly to about a hundred people in Birmingham and district, some of whom have not been able to attend a service for years previous to the introduction of a telephonic service.

Glasgow Tramways.—A deputation representing the Glasgow Corporation last week went for a week's tour for the purpose of enquiring into the various methods of tramway traction in use throughout the country. The party was headed by Bailie Paton, accompanied by Bailies Wallace and Stevenson, Councillors Bell and Thomson, Mr. Rankine, C.E., and Mr. Arnott, the city electrician. They commenced their enquiries at Chester, where they witnessed some experiments with low-pressure compressed-air cars by Messrs. Hughes and Lancaster. From Chester, on the Monday night, they proceeded to Birmingham, where on the following day they had an opportunity of inspecting the electric and cable tramway system of that city. The deputation afterwards journeyed to London, where they were shown the electric storage cars at Barking-road, and afterwards the conversion from horse to cable traction of the South London tramways at Brixton. Setting out again for the North, Bailie Paton and his associates arrived in Leeds on Thursday night, and spent the day in that town. They were received by Alderman Firth, the chairman of the Corporation Highways Committee, and Mr. Prince, superintendent of the highways department. In the morning they inspected the electric car section on which Leeds people are conveyed from Sheepscar to Roundhay Park, as well as the site of a proposed extension of that branch of the tramway system from Beckett-street to York-street. The deputation were conducted over this recently-made experiment with electric car by Mr. Davenport, the managing director of the Thomson-Houston Company, and by Mr. Graff-Baker, the lessee of the Roundhay Park line. The party expressed their gratification and interest in all they had seen.

City Electric Railway.—At the meeting of the Commissioners of Sewers on the 21st, Mr. Clarke presented the report of the Local Government and Taxation Committee, asking the Court to order the presentation of petitions against the following Bills, with authority to engage the services of an engineer: Central London Railway, City and South London Railway (Islington extension), Great Northern and City Railway, Royal Exchange and Waterloo Railway, and Waterloo and City Railway. Mr. Clarke said the committee reported that they considered the time had arrived when the Government should consider the whole question of these electric railway enterprises, because their number seriously threatened many portions of the City of London. There was a proposal to interfere with several important public ways in the City; while there was another proposition to construct a tunnel near London Bridge, which was giving the Bridge Committee much anxiety. There was a proposition also by one of these railway companies to take up underground the vacant space between the Mansion House and the Royal Exchange. But by agreeing to the report of the committee the Corporation would possess a *locus standi* before a committee of the House of Commons when these questions were being considered. It was considered very necessary that Colonel Haywood should be consulted, together with perhaps another eminent engineer like Mr. J. Wolfe Barry, because the committee felt that Colonel Haywood knew more about the wants of the City streets than any other man in London. Mr. Deputy Bedford agreed that this matter was of immense importance to the City of London, and would have to be approached with the utmost care and watchfulness. Mr. Deputy Haywood asked if the Waterloo and Exchange Railway Bill had not been withdrawn. The Remembrancer replied in the negative. The report of the committee was then unanimously adopted.

Coast Communication and Defence.—The following information and statistics have been sent us by Mr. J. Lawrence-Hamilton, M.R.C.S., late honorary president Fishermen's Federation, of 30, Sussex-square, Brighton: The United Kingdom has an indented coast line probably exceeding 10,000 miles. Telegraph overhead wires and posts at, say, £40 a mile would cost upwards of £400,000. To supplement its 681 coastguard stations, which in case of war are to be increased by 78 extra stations, the United Kingdom requires upwards of 700 new signal stations, which at about an average rate of £1,200 each might cost, say, £840,000. Besides shore lighthouses, the United Kingdom possesses probably upwards of 100 rock lighthouses without submarine cables. The cable from Tory Island rock lighthouse to the shore cost about £6,000, which sum may be often exceeded for similar purposes. Cables connecting lightships to the shore are easily snapped by the to and fro swinging of the vessels, especially during storms, gales, etc. Excluding the connection of lightships to the shore, a complete coast communication would probably involve an initial expenditure exceeding £5,000,000, and over £350,000 a year for maintenance. The 1891-1892 surplus postal profits have been estimated at £3,371,000, which income seems likely to increase in future years. For saving life and property at sea, as well as for defensive purposes, our coast communication should be completed with the annual surplus postal profits. French trawlers, manned exclusively by naval reserve crews, fish all round Cornwall, the west and north-west Irish coasts, making frequent visits. The French Naval Reserve is intimately familiar with our Irish coasts, which in some situations are unguarded by coastguards and without telegraphs, except at a distance of upwards of 35 miles. Even then the "nearest" telegraph station may be only open from 8 a.m. to 8 p.m., and closed all Sunday. Mr. Lawrence-Hamilton, in addition to furnishing these pregnant statistics, further suggests that the United Kingdom could raise from our British fisherfolk a volunteer defensive naval reserve of about 100,000 men, and a volunteer defensive cadet reserve of 100,000 fisherboys.

A Sky Timepiece.—Our attention is called to an invention by which an ordinary clock is practically magnified to such a size as to permit of its being seen for a radius of 50 miles around. This is a big statement to make, and probably hardly credible at first, but it has an element of possibility in it. It is, we understand, a recent invention of Mr. H. Y. Dickinson, of 56, Gray's-inn-road, London, who also owns the patents. The actual time-indicating clockwork is the same size as an ordinary turret clock, but connected with this there is a second train of clockwork which is controlled by the clock proper, and is put in motion every minute, when it whizzes round (regulated by an ordinary fan governor) and actuates an electric flashing lens, in much the same way as the striking mechanism of an ordinary clock acts. The beam of light reflected into the sky goes through the movement of a striking hammer when the clock is indicating the even hour. This is, however, only one signal made by the apparatus. Another symbol is used for every complete interval of five minutes, and yet another for odd minutes. Thus, supposing the time to be 7.27, this would be denoted by the seven beats in the first instance, then five other signs (indicating 5 × 5 minutes), then two short, sharp flashes for the two odd minutes. This operation is gone through every minute, the signalling taking on an average about 10 seconds. Of course, it will be evident to anyone that the system of signal used can be modified to suit any conditions, and, further, that the code has only to be understood to enable anyone with a little practice to read this sky clock with ease. Such apparatus placed in the centre of this vast metropolis might be a great boon to the inhabitants, and that after a little practice the time would be read off as easily as from an ordinary time dial. There would be no excuse for the vagaries of time now indicated in most houses, and even public buildings, where if the timepiece is within a few minutes of the actual time it is allowed to pass. With this clock at work it would only be necessary to run to the front door to see the time so as to correct the kitchen clock, or for the City man catching his train in the evening to check his watch. At the present time many clocks in large offices and stations are electrically synchronised hourly from a standard clock, but this convenience has to be paid for, and is rather costly. Mr. Dickinson's clock would not only permit of clocks being synchronised, but watches too, and for no charge. We are afraid the inventor will have some difficulty in getting the authorities in London to take up the matter, but what a chance for some of the large advertising firms! A sum of money spent on a public benefit of this nature would keep the firm's name with which it was coupled before the public in a more lasting manner than could be gained from the ordinary advertising channels. The invention is worth trying, at any rate, at an exhibition. Mr. Dickinson had better get the Electrical Exhibition to take it up and give London "Crystal Palace time." If it were successful in London, it would be followed in all the most important cities throughout the world as a public necessity, and handsome royalties might be expected by the inventor. We believe something of the sort has been done in Sydney, but this, if we remember, is an hourly flash. We understand that the first of Mr. Dickinson's sky clocks is now in course of erection, so that the public will shortly have a chance of judging of the promised effect.

OUR PORTRAITS.

Jackson, Colonel R. Raynsford, born in 1823, is the son of the late Captain Jackson, R.N., J.P., of the county of Lancaster, honorary colonel of the 3rd Brigade of Lancashire Artillery Volunteers from 1861. He was partner in the extensive cotton spinning and manufacturing business of the late Sir Wm. Fielden, Bart., of which, after retirement of Colonel Montague Fielden, he subsequently became sole proprietor. He was chairman of the National Telephone Company from its formation early in 1881 until the amalgamation of the principal telephone companies into one company, which retained the name of the National Telephone Company, in May 1889, when he was elected, and has continued, vice-president of the company.

Holden, Captain Henry Capel Lofft, Royal Artillery. Born in Cheltenham on the 23rd January, 1856, passed the Royal Military Academy, Woolwich, and obtained his first commission in the Royal Artillery in August, 1875. He served in India from 1877 to 1881, and whilst there carried out a number of experiments in telephony and telegraphy, having been granted the singular favour of a license for a private line by the Government of India for this purpose. Since 1886 he has been in charge of the department for the proof of guns and experiments therewith in the Royal Arsenal, Woolwich, and he has invented and designed whilst there many electrical instruments connected with his profession. He was deputed by H.M. Secretary of State for War to visit and report upon the electrical appliances at the Paris Exhibition of 1889, as well as that at Frankfort in 1891.

Sketch of the Stand of the Acme Electric Works at the Crystal Palace.

Hammond, Robert. Born in 1850, and took up electrical engineering in connection with his Middlesbrough business in 1879. He is now the sole partner in the firm of Hammond and Co., electrical engineers, of 117, Bishopsgate-street Within, London, and Middlesbrough. He is the accepted candidate for the Hallam division of Sheffield. He was the first purchaser of a Brush concession, and for some time pushed the Brush business very vigorously, but as in those days the Brush Company had no reliable incandescent machine, he severed his connection with them and obtained the co-operation of Mr. Ferranti. Hammond and Co. devoted themselves in the early days to the lighting of iron works, steel rail mills, etc., and fitted installations into the principal iron works of the country. As early as 1881 Mr. Hammond took up the problem of the distribution of electricity from central stations, and founded the pioneer stations at Brighton, Eastbourne, and Hastings. In recent times he has laid down the West Brompton station of the House-to House Electric Light Supply Company, and one of the largest electric light stations on the Continent for the Electricity Supply Company for Spain at Madrid. He is now executing the contract which the Electrical Engineering Company of Ireland made with the Dublin Corporation.

Stuart, Captain A. M., of the Royal Engineers. Like many of his colleagues in that celebrated corps, he has had considerable experience with military electrical work. Entered the Royal Engineers in 1879, and was engaged in submarine mining and telegraph work from 1881 to 1884. During the succeeding years, from 1884 to 1887, experience was gained in London and on the Egyptian frontier in all that concerns military telegraphy. For the next two years Captain Stuart was with the southern division of the Post Office telegraphs, and since that time to the present has been assistant instructor in electricity at the School of Engineering, at Chatham.

Taylor, Colonel du Plat, although not now included within the ranks of electrical engineers, has claims to member-

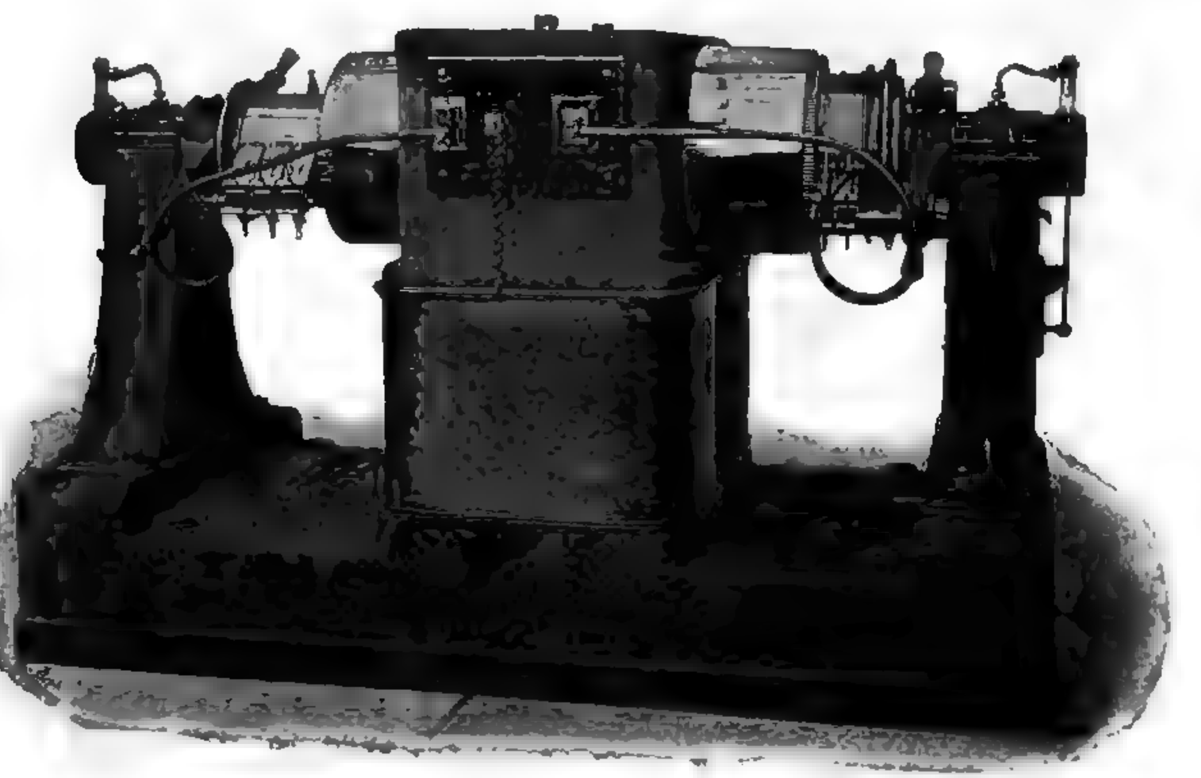
ship with the fraternity. His business life commenced under the ægis of the Postmaster-General, and so far his connection with the Post Office can hardly be said to have been severed, inasmuch as he is the colonel commanding the Post Office Volunteers.

THE CRYSTAL PALACE EXHIBITION.

We have so often referred to the enterprise of the Crystal Palace District Company in carrying out under great pressure the Sydenham-hill lighting station, and have described so much of the work, that only one important link remains practically unmentioned. We can now remove the veil and refer to the apparatus. Perhaps the one feature in the supply of current to the Crystal Palace by the District Company is the adoption of fairly high-pressure continuous currents generated at the central station and transformed downwards by continuous-current motor-generators at the distributing station. It is unnecessary in a more or less popular description of exhibits to enter into technical details that can be left for a future time, and undoubtedly a good deal of discussion will range around the use of this apparatus. The general reader knows that the use of motors with continuous currents has long been practical. Such motors are in use the world over, and great advances have been made in obtaining in one shape or other motors for alternate currents, but the use of such motors is not general. Restricting our remarks, then, to continuous currents, it is well known that electrical energy can be given to a motor and mechanical energy obtained therefrom. This mechanical energy can be used to turn another dynamo or to turn a lathe. In the motor-generator the mechanical energy obtained from the motor is used to turn a dynamo, and to simplify matters, both motor and dynamo are erected upon one shaft. It is simply a combination of two machines, but a combination which increases the efficiency of the apparatus as a whole. In the Crystal Palace building are nine of these motor-generators, eight of which are in use, as stated in our article of last week, by the Crystal Palace District Company, and are to be found under the floor of the main building. The ninth is to be found in the Machine Department, at the stand of the **Electric Construction Corporation**. The latter differs from the former in that it is self-starting—that is, requires no extraneous current to excite the magnets. The Palace machines, as illustrated herewith, are wound to give an output at the secondary terminals of 110 volts, 360 amperes, when supplied with primary current at an E.M.F. of 1,000 volts, and runs at a speed of 550 revolutions per minute. The efficiency is stated to be as high as 91 per cent. with full load, and over 81 per cent. down to one-third load. The bearings are fitted with specially-designed oil pumps so as to secure continuous lubrication, allowing the machine to be left for lengthened periods without attention. A similar machine to this has been running at the Chelsea Electricity Supply Company's station for the last 18 months, and recently a second one has been added. The company have also in hand a complete central station for Oxford, where high-tension continuous currents with these transformers has been adopted.

The Acme Electric Works, Stand 170, have an exceedingly prettily-arranged exhibit, which includes examples of their various makes of instruments, switches, and switchboards.

Messrs. Woodhouse and Rawson, Stand 103, at the south end of the North Nave, have a large exhibit of their various manufactures. It is rendered specially noticeable by reason of two large diamond-shaped pieces of wood which are suspended over it. Grooved letters, W. & R., are formed by fitting together pieces of silvered glass. In the grooves thus formed incandescent lamps, coloured alternately blue and red, are placed, and clockwork is arranged to alter the connections at certain intervals and so form the letters first with red-coloured lamps and then with blue. The diamond containing their initials is the company's well-known trade-mark.

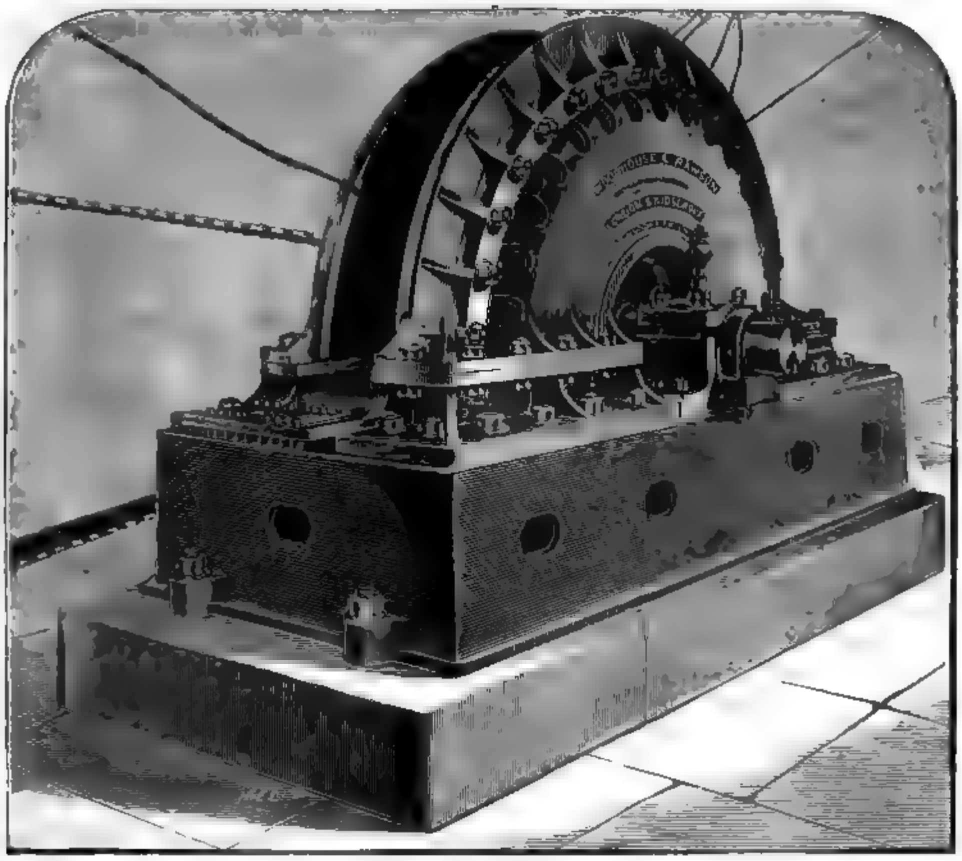


The Electric Construction Corporation's Motor Generator.

A prominent object in the stand is the Kingdon dynamo, illustrated herewith, which has more than once been fully described in our columns. In this type of alternator the armature and field magnet are both stationary, and the necessary alternations in magnetic field are obtained by revolving in front of them a large iron wheel. What is very much to the purpose is that this type of alternator is being used in central stations, as at Woking. In the exhibit it is driven by means of leather link belting by a Woodhouse and Rawson motor, supplied with current from the mains of the Crystal Palace and District Electric Lighting Company, Limited.

The necessity for a good motor for launch work led the company to design the "Woodhouse and Rawson," several sizes of which are shown. Special pains have been taken

to keep the centre of gravity as low as possible, and also to render the armature waterproof. These and other improvements, among which may be mentioned the use of carbon brushes, are claimed to have resulted in the production of a reliable motor which just now is receiving a good deal of attention. The uses of electromotors are daily increasing. It is only during the past year or two that Englishmen have begun to appreciate the many advantages of such machines. Their economy is now a well-established fact, and wherever an electric current is easily available, their application is daily extending. In the larger sizes, especially when intended for use as a dynamo, the design is slightly altered, the magnetising coil being placed at the side of the armature instead of the top.



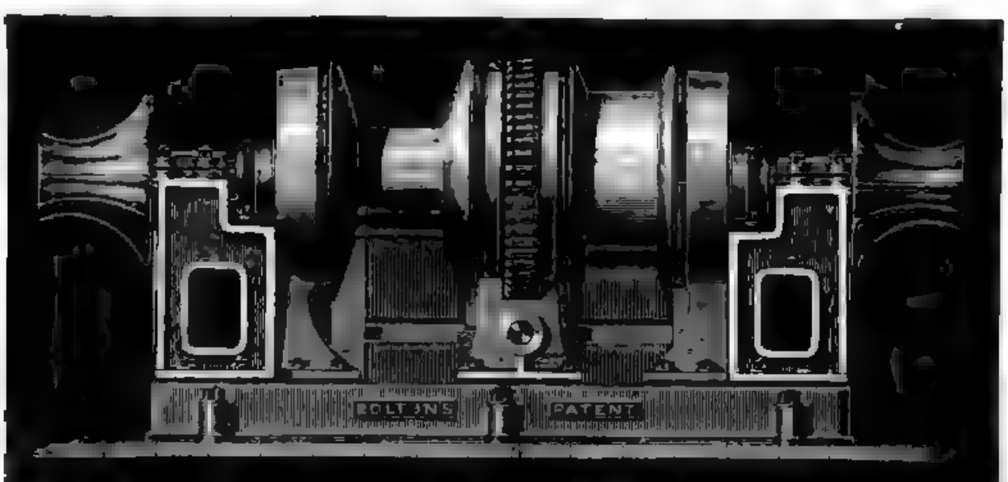
The Kingdon Dynamo.

One of Bolton's patent electric winches is exhibited in action. The axle of a Woodhouse and Rawson motor is attached to worm gearing, which reduces the speed to the required limit. These winches are specially suitable for use on board ships on account of their noiseless action. The winch consists of an electric motor, which is geared on to a centre gear drum. At each end of this drum, which is always revolving, the hoisting drums are gripped by friction. The only work the man in charge has to do is to put these drums in or out of gear. When in gear the load is hoisted and when out it is lowered by gravity.

To meet the demand for an electrical governor for controlling turbines and engines driving dynamos, a special form of the Porte-Manville type is shown. The variations in the strength of an electric current are made to actuate a ratchet-wheel, and so control the movements, either of the connecting-rod between the mechanical governor and the steam engine, the valves of a turbine, or a switch which varies the resistance in circuit in the exciting circuit of a dynamo.

Above the stand a crown of six Midget arc lamps is shown. These lamps, it is said, are rapidly becoming favourites for lighting small areas and large buildings, and form a very economical means of illumination. Hitherto the great unsteadiness of small arc lamps—*i.e.*, lamps of about 500 c.p.—have prevented their coming into use, but now that this difficulty has been overcome we may expect their use to rapidly increase.

The company show various types of switches suitable for carrying large currents up to 1,000 amperes, or sufficient



Electric Winch.

to light over 1,600 incandescent 16-c.p. lamps. Double-pole switches have lately come into use, and several special designs of these are shown. These are suited for installations where very large currents are used; while other designs are suitable for smaller currents. Where high electrical pressures are used, the type illustrated is found convenient.

Some years ago the company introduced the Cunynghame magnetic cut-out. This instrument, which has been widely used and appreciated, is inserted in an electric circuit for the purpose of breaking connection when the current exceeds a predetermined limit. The type now adopted and shown at the Palace is slightly different from the original design. The current of electricity in passing around the pivoted coil creates a magnetic field, and tends to move in such a direction as to enclose more of the iron core. As the current increases this tendency to move becomes stronger, until at last the

ends are quite withdrawn from the mercury, and the centre of gravity of the coil is moved to the other side of the pivoting point, and the coil falls over by the force of gravity, thus permanently breaking the circuit. These instruments are of great use for such purposes as charging accumulators, protecting an electric light installation from risk of excess current should the engine be overrun, and many other contingencies which electrical engineers often meet with. These are shown in all sizes, one collection of six forming a complete series capable of breaking the circuit at any strength from one to 1,000 amperes.

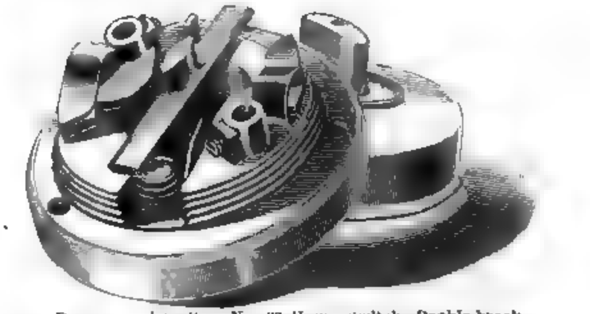
A novelty just introduced is a contrivance for switching in an electric circuit at any predetermined time. A clock is set to a certain hour, and it is so arranged that its movements release a pivoted arm, which, when free, fall into two mercury-cups, and make electric contact. Another useful appliance is the lavatory switch. It is designed for the purpose of economising the use of lamps, and is affixed to the door frame so that alternate openings and closings of the door turn the light on or off.

The expiry of some of the more important telephone patents having opened the telephone market, this company have introduced several new forms of instruments, and are making domestic telephony one of their chief specialities. The illustrations give some idea of the designs exhibited, which are loud-speaking and reliable.

The switchboard illustrated is one of the latest designs, and contains several novel features. It is intended for use with compound-wound electromotors, and the locking arrangements of the switch are so arranged to first of all put the series-wound coils in a position to increase the strength of the magnetic field; and afterwards, when the magnets are fully excited, to reverse the direction of the flow of current through them, so as to allow them to perform their proper compounding function. The handles are locked by the vulcanised fibre rings, so that it is impossible to turn them in any other order than that necessary for performing the necessary changes in the electrical connections. The other exhibits on this stand are well worth careful examination.

At the end of the South Nave, near the fountains, is the exhibit of **Messrs. Dorman and Smith,** the well-known manufacturers of electric switches and fittings. It is well worth a visit from electrical engineers, as me new and ingenious types of switches and accessories are shown. Small switches in brass and porcelain, the latter artistically decorated, are shown in great variety. The best-known of the switches is the ordinary house type, with quick break and sudden release handle, of which some 100,000 are in use. One of the latest introductions is that here illustrated, No. 60 pattern. The contact arm, after breaking current, is quietly brought to rest by the same spring which accelerates its movement when switching off the current—thus securing a non-percussive action, which dispenses with the jarring which is so often a source of trouble by loosening the wires in the terminals. A very useful and rather peculiar double-pole main switch is also exhibited. They are made of gunmetal on paraffined slate. They have an instantaneous break, however slowly the handle may be turned, and this is secured either by a tension spring or a coiled spring round the shaft, the latter being now preferred. The action is very satisfactory and the workmanship excellent. We also show a six-way accumulator switch, the change in contacts of which are made instantaneously on moving the handle, thus avoiding the short-circuiting of cells.

Dorman and Smith's Quick-break Switch.



Dorman and Smith's No. 60 House Switch, Double-break.

Dorman and Smith's Carbon Break Switch.

Dorman and Smith's Double-Pole Main Switches.

Still another kind of switch which should be mentioned is shown at this exhibit. Messrs. Dorman and Smith are sole makers of Siemens patent carbon contact switch. The final break of this switch is between two carbon blocks, and this arrangement is useful in keeping the metallic contacts clean and free from burning. A D. and S. spring is used to prevent the contact from remaining in an arcing position. Lampholders shown by this firm are worthy of attention. One or two of the D. and S. patterns are much appreciated by the trade. Samples of their wall-sockets (double peg, and also concentric), ceiling roses with their patent arrangement for taking the strain off the wires, besides cut-outs of all kinds, are exhibited. A handsome and very serviceable balance lamp pendant is shown, with cut-glass globe—any kind of shade can, of course, be used therewith. Brass and cast-iron ship and mill fittings of all descriptions, including Sunbeam lamp fittings, are exhibited, and many of these being specially designed for colliery lighting. Switchboards, of which Dorman and Smith make many varieties, are represented by a large enamelled board in walnut frame, mounted with their main switches of various types.

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With this issue of the Paper is given a Supplement containing Portraits, taken from photographs, of **Colonel R. Raynsford Jackson, Colonel du Plat Taylor, Captain H. C. L. Holden, Captain A. M. Stuart, and Mr. Robert Hammond.**

Every reader should see that he gets this Supplement, and non-delivery with the Paper should be reported at the Publishing Office.

DEPUTATIONS AT THE PALACE.

The notice-board at the Crystal Palace will, from now to the end of the Exhibition seldom, be free from a notice that such and such a deputation will visit the Palace on certain days. Yesterday and to-day the Mayor and the members of the Derby Corporation have been seeking information. Last week we recorded the visit of a deputation from Nottingham, and prior to that, from Blackpool. Other deputations are to follow, each seeking for certain information. We have already suggested to exhibitors that they be well represented and prepared to receive such visitors. It may, however, be more necessary to advise the deputations than the exhibitors. The latter are sellers, and keen to do business; the former are likely purchasers, and every effort will naturally be made to give them a bias in this or that direction. No doubt the sellers are somewhat anxious to book definite orders, but instead of benefiting themselves they may do harm by showing too great an eagerness. They know that the patronage of one town will amply repay for the trouble, anxiety, and expense of the exhibition, and would like an immediate contract as the result. Corporation business does not move so rapidly as all this. Deputations do not come provided with a commission to order a central station and all the appurtenances thereof. They come to get provided with answers to opponents, and arguments to induce constituents to agree to follow the stream of progress. It must be regretted that several well-known firms have held aloof from this Exhibition. The time is very opportune. Men's minds are turning with favour towards electric lighting, and those who exhibit at the Palace will certainly be put in a favourable position in connection with those places from which deputations come. For example, one of the most important questions with which members of corporations will concern themselves, is that of mains. What kind of mains will at the same time be efficient and give least trouble in laying and in maintenance? Electric light people must not expect the roads and streets of a town to be given up to their tender mercies for any length of time. We have heard many absurd remarks as to the requirements of borough engineers or surveyors who watch over the interests of the corporation, but in the matter of laying of mains many such engineers could give valuable information. Exhibitors, as a whole, have not thought the question of mains of sufficient importance to show actual examples, but the exceptions, Messrs. Crompton and Messrs. Siemens, have short lengths of mains as they suggest mains should be laid. Where corporations become their own undertakers, they will attempt to obtain that system which conforms closest to their views in not at any time interfering much with ordinary street traffic. Messrs. Siemens should have the benefit of the results at Bradford. Deputations should insist upon authoritative information. This can undoubtedly be forthcoming, and if, as we presume, it is quite satisfactory may largely influence the use of armoured cable, and

a simple trench with no provision for hauling out a cable for repairs. It may be much cheaper and better in all respects to follow such a system when the conditions are favourable, than to use a more costly one. Messrs. Crompton, again, have the experience obtained at Kensington and elsewhere, and should be able to show under what circumstances the naked copper strips and concrete channel is best. Sufficient time has not passed to hope to obtain authentic statistics as to the faults which develop in electric light mains. It is absolutely certain, however, that faults do and will occur, and the repair of these will become one of the recognised duties of central station work. The initial cost of laying the mains must be considered in connection with their maintenance, for though one way may be cheaper than another, the tables may in time be turned and the dearest become the cheapest, through cost of maintenance. Our advice, then, to deputations is to get all the information possible on this subject. It is almost entirely a matter of business, and requires little scientific knowledge. Of course the decision as to the system of distribution and the calculation of the size of mains is another matter. Each deputation will have a definite object in view, probably the lighting of a particular town. They will be able to give approximately the area to be lighted ; the class of lighting—residential, factory, or street ; the position at which a central station might be put ; the consumption of gas in the district ; the cost of gas and its quality. They will expect in return some fairly definite information as to what could be done with electric light, the unit of power to be employed, the kind of prime mover to be employed, the kind of dynamo, and the reasons therefor. The more information these deputations can obtain, the better able will they be to convince their fellow-townsmen of the advantages of electric lighting. It may not be amiss to warn exhibitors to make it quite clear as to which are their exhibits and which not. Even now there are arc lamps and arc lamps. Visitors will not fail to recognise this, and those that are so-so, must belong to the right owners. The Machinery Department contains some widely divergent types of prime motor, an exceedingly interesting display, as are also the combinations of engine and dynamo. Much of the work of next winter will depend upon the impressions received now.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CRYSTAL PALACE EXHIBITION.

SIR,—On revisiting the Electrical Exhibition at the Crystal Palace, I was surprised to find how greatly it had improved. Everything is now in full swing. The spirit of emulation seems to be spreading among the exhibitors, for if one has a pump or big accumulator, or even a crane, another exhibitor must have one like it or bigger, if possible. The result is that most of the stands are getting crammed with interesting objects, although in one case the fascinating smiles of the charming maiden who presides over the Hedgehog more than compensates for the paucity of the exhibit.

I notice that anything that makes a noise or goes round is sure to attract. When the young gentleman in charge switches on the field current to the Kingdon alternator and makes it roar, a crowd collects immediately, and two minutes after the electric crane starts you cannot get near it. The telephone-room is doing a tremendous business, and it is very interesting when the organ is not playing, and altogether, what with the awful diver that frightens the children at one end, the awfuller choir that frightens the old ladies at the other, all visitors seem thoroughly pleased with the evening's entertainment.—Yours, etc., X.

THE LIFE OF INCANDESCENT LAMPS.

SIR,—You always take such a strong interest in all practical questions that I am tempted to trespass on your space in order to ventilate one that has been perplexing me a great deal lately, and that is, the short duration of Edison-Swan incandescent lamps. From a little enquiry I have made, I am led to believe that other electrical engineers have been also noticing this during the last few months, and it would be most valuable if through your courtesy opinions could be exchanged on this point. In plain words, is it or is it not the case that lamps are not standing as they used to do ? To those engaged in installation work this is a serious question, as nothing disgusts a customer more than, after having gone to a certain expense in an installation, to find that he is obliged almost every week to be putting in one or more new lamps. It may be that my recent experiences are unique, but I don't think so, and, at all events, should be grateful to any practical men with large opportunities of judging who would give their views.—Yours, etc., EXPECTANS.

Feb. 23, 1892.

ELECTRIC TRAMWAYS.

SIR,—In your issue of the 19th inst. you publish the first instalment of a paper by Mr. W. G. Carey, on "Electric Tramways on the Overhead or Trolley Wire System," and we shall be obliged by your giving us space to reply to some of his remarks in regard to the use of conduits in lieu of overhead wires for tramway traction. Mr. Carey remarks "that it cannot be doubted that many of the communities are deterred from adopting it [electric traction] only by their prejudice against overhead wires," and at the same time his paper endeavours to show that no other method of electric traction on tramways is practicable. His condemnation of conduits is wholesale and complete, but we venture to think scarcely accurate. He considers there is little reason to hope that "an open-slotted conduit could ever be made a success in our streets, its fatal weakness being the impossibility of keeping the conduit free from mud and water." As a matter of fact successful conduits have been constructed and worked—for instance, at Blackpool and in Budapest, as well as at Northfleet, where a conduit line was built which was absolutely satisfactory both mechanically and as regards the question of interference through mud and water. Perhaps, however, Mr. Carey prefers to confine himself to the American failures, where, he says, "thousands of pounds were expended on four practical experiments." We have seen a sample of the conduit that has been used in American attempts, and if this was a fair example of the four practical experiments we are not at all surprised at their being absolute failures. We agree with Mr. Carey as to the importance of proper provision being made for keeping the conduit free from wet and dirt, but we do not admit that this presents any insuperable difficulty. The conduit system which we advocate where overhead wires are not permitted has special provision in regard to keeping the conduit clean, in addition to other improvements, and how far we have succeeded in this direction is, we think, fairly well indicated by the remarks which occurred in your issue of April 25, 1890, in regard to our system, where, after pointing out the requirements in underground conduits, you were good enough to say : "*All these points are obtained in the new system with no chance of stoppage through mud or dirt.*" We recognise the advantages of the overhead system of traction, and, as engineers and not contractors, recommend it, where permissible, on account of the somewhat smaller

capital involved, but we protest against a statement that, apart from this increased capital cost, equally good results cannot be secured by the use of an efficient conduit system. No doubt Mr. Carey, from his connection with the Thomson-Houston Company, desires to cry up his wares and to depreciate other methods of traction, but he should surely have some regard to facts, although they are doubtless inconvenient to him.—Yours, etc.,

A CORRECTION.

SIR,—Respecting your article under the heading of "Woodhouse and Rawson" in your issue of Feb. 12, we beg that you will kindly correct remarks made in same which carry a false impression with regard to our work—namely, that the model of the electric launch referred to is a model of the "Glow-worm," which was built by us for Mr. Andrews Pears, and not by the Thames Electric and Steam Launch Company; and also that we have no connection whatever with the Thames Electric and Steam Launch Company, which your article might lead readers to infer. We should be obliged by your kindly inserting this contradiction in your next issue.—Yours, etc.,

PRACTICAL INSTRUMENTS FOR THE MEASUREMENT OF ELECTRICITY.

BY J. T. NIBLETT AND J. T. EWEN, B.SC.

IV.

(Continued from page 159.)

MEASUREMENT OF ELECTRICAL RESISTANCE.

Having now briefly described the several electrical units, and ascertained the nature and characteristics of electrical resistance, we shall proceed to describe and illustrate the different methods used for determining the resistances of various substances, and the forms of apparatus usually employed in these measurements. Current indicators such as simple detectors and zero instruments play a most important part in these determinations, but as the description of these comes naturally under the head of current-measuring instruments, we shall merely briefly refer to them here, leaving the full description of their construction, and the theoretical considerations involved in their manufacture, until current detectors and zero instruments are being considered.

Resistance of Conductors.—Before commencing to determine accurately the resistance of a conductor, it is advisable to ascertain whether this resistance is likely to be a high or a low one. Perhaps one of the best methods for determining approximately the resistance of a conductor is that known as the *Substitution Method.* This method can be used either with or without the assistance of a shunt; in the former case it is usually designated the *Simple Substitution Method,* and in the latter, the *Shunt Substitution Method.* For either of these two methods, the necessary apparatus is: a sensitive galvanometer, such as a Thomson reflecting, a d'Arsonval, or a Deprez; one or two low-resistance battery cells, capable of giving out current without material variation of potential, such as the well-known Daniell cell, or preferably cells of the lead secondary type; a variable known resistance, which may be in the form of a box containing calibrated resistances, a metre bridge, or a graduated rheostat; and a suitable contact-maker. If a variable known resistance is not available, an unvariable one, such as a coil of wire whose resistance is known, may be used instead, as explained. A convenient arrangement of the apparatus for measurements by the Simple Substitution Method is illustrated diagrammatically in Fig. 1.

Having fitted up the apparatus as shown with the resistance to be measured, R, in circuit, note the deflection of the galvanometer on the completion of the circuit. Now remove the unknown resistance, R, and substitute for it the variable known resistance, R_1, and so regulate it that, on again completing the circuit, the galvanometer needle gives exactly the same deflection as before. This now indicates that the resistance of the whole circuit is just equal to that in the former case, so that the resistance shown by R_1 must be the same as R, the resistance being determined, or

$$R = R_1.$$

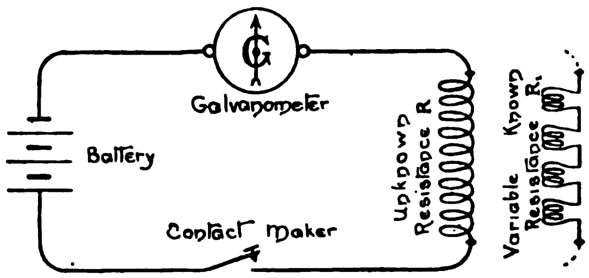

FIG. 1.—Simple Substitution Method.

This arrangement can also be employed when the known resistance, R_1, is not variable, if the scale of the galvanometer is accurately calibrated. For this purpose the resistance, R_G, of the galvanometer, and R_B, of the battery must be known.

Then if d be the galvanometer deflection when the unknown resistance, R, is in circuit,

and d_1 be that with the known resistance, R_1;

since, by Ohm's law, the whole resistance of the circuit in each case is inversely proportional to the current flowing, and therefore to the galvanometer deflection, we have—

$$\frac{R + R_G + R_B}{R_1 + R_G + R_B} = \frac{d_1}{d}$$

$$\text{and } \therefore R = \frac{d_1}{d}(R_1 + R_G + R_B) - (R_G + R_B).$$

Usually, in measuring resistances by this method, the internal resistance of the battery employed is but the fractional part of an ohm, while the resistance of the galvanometer would probably be some hundreds of ohms, so that the former is negligibly small in comparison with the latter. Then, instead of the foregoing formula, we may write:

$$R = \frac{d_1}{d}(R_1 + R_G) - R_G.$$

For measurements by the *Shunt Substitution Method,* the apparatus is arranged as indicated in Fig. 2.

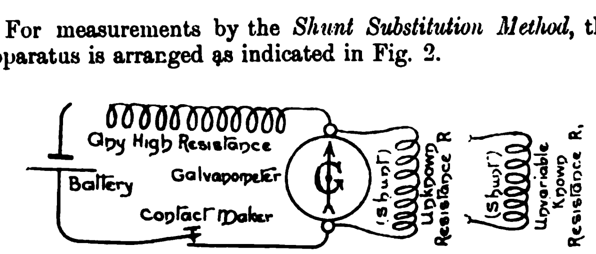

FIG. 2.—Shunt Substitution Method.

In this case the resistance to be measured, R, is connected up as a shunt to a sensitive high-resistance galvanometer, which forms part of a circuit in which are also a single voltaic cell and an added high resistance, as shown. It will be seen from this arrangement that the actual current flowing through the galvanometer and shunt together will be very small, and that most of this current will flow through the shunt itself, owing to its own resistance being low, relatively to that of the high-resistance galvanometer. Owing to the high resistance in the main circuit, any alteration in the shunt itself makes very little difference to the total current passing through the shunt and galvanometer together, its chief effect being simply to proportionally vary the amount of this current which flows through the galva-

nometer, so that the reading of the galvanometer is really a measure of the resistance of the shunt.

Thus, if d be the galvanometer deflection when the unknown resistance, R, constitutes the shunt,

and d_1 be that when the known resistance, R_1, is substituted for it;

then we have—

$$\frac{R}{R_1} = \frac{d}{d_1}$$

$$\text{and } \therefore R = R_1 . \frac{d}{d_1}.$$

ELECTRIC TRAMWAYS ON THE OVERHEAD OR TROLLEY WIRE SYSTEM.*

BY W. GIBSON CAREY.

(Continued from page 188.)

Three methods of supporting the trolley wire are pursued depending upon the position of the tracks in the roadways. By far the most common of these is what is known as the "span-wire" system, in which the poles are planted at the edge of the footpath on either side of the street, and the trolley wire hung from a span wire stretched between them. On suburban roads where ornamentation is not necessary, wooden poles are usually used as, in the United States at least, they are far less expensive, and the insulation which they interpose between the trolley and the ground is an additional safeguard against accidents. In city streets, however, the use of wooden poles, which must of necessity be larger and more unsightly, is rarely allowed, and iron poles of various designs, often very handsome and ornamental, are used. The best of these are made of three sections of tubing, of about 6in., 5in., and 4in. diameter respectively. They are firmly bedded 6ft. deep in concrete, and must be strong enough to stand the lateral strain of the span wire without a greater deflection than 6in. at the top. Into the top of the pole is fitted a wooden plug boiled in paraffin and protected by a cast-iron cap. This serves to insulate the span wires from the ground. The span wires should be of No. 5 galvanised steel, and where an uncommon strain occurs two of these may be advantageously twisted together into a cable.

The method of putting up span wires is as follows: One end of the wire is securely fastened to an eye-bolt in the insulator at the top of the pole by means of an American telegraph splice, or one of the many special devices made for the purpose. The other end is then carried to the top of the opposite pole and the two poles are pulled together by means of a block and fall, or by a ratchet hauling clamp, until there is a strain on the span wire of 800lb. or 900lb. The span wire is then made into the eye-bolt on the second pole in the same manner as on the other. It is absolutely necessary that this apparently great strain should be put upon the span wire, or otherwise it will have a sag when the weight of the trolley wire comes upon it, which is fatal to a neat appearance of the line. The hangers or supporting devices used vary greatly in design to meet the requirements of special cases, but too much stress cannot be laid upon the importance of making them of ample strength. It is important, also, that all hangers and insulators should be made with regard to uniformity. The only part liable to deterioration is the insulators. These should therefore be made of a standard pattern, and the hangers arranged for their reception. In this way any fault can at once be remedied at a trifling cost. The hangers are placed in position by means of a plumb-bob, and should be so arranged that the trolley wire will come as nearly as possible over the centre of the track throughout its entire length. On curves the chords, where possible, should be made so short that the trolley wire is in no place more than a few inches out of the centre. When the hangers are in position, the trolley wire is stretched loosely along and hung temporarily from the span wires, and then pulled up tight by means of a block and fall. Lugs, known as ears, with a groove milled out along the bottom side to fit the wire, are then soldered on to the trolley wire beneath the span wires. These ears are arranged for the reception of an insulated bolt, the head of which is held firmly in the hanger, and the trolley wire is thus securely fastened to the span and thoroughly insulated therefrom. We have now between the trolley wire and the ground the insulation in the hanger itself, which may be of ebonite or moulded mica, and the wooden plug in the top of the pole. This is, in actual practice, so perfect that even in very wet weather the insulation resistance will be not less than 15,000 to 20,000 ohms per mile. It will be readily understood that no rule can be laid down for the design of the overhead wiring. The length of the spans of the trolley wire, the position of the poles, span wires, and pull-offs, etc., must be designed to suit each special case, and unless this is most carefully done troubles from breaking wires or unsatisfactory working of the trolley is sure to follow. On single-track roads, with passing places, frogs of various design are used. These are so made that the trolley will automatically follow the wire, and need no attention whatever from the conductor of the car. Where necessary, supplementary feed-wires are carried either on the poles, or, preferably, in armoured cables laid underground and connected at intervals to the trolley wire.

As has been said, no rule can be laid down for the distance between the poles, but this should in no case exceed 125ft. On suburban roads, where the track is principally straight, this distance can be pretty closely adhered to, but upon curves and city streets it must often be considerably reduced, averaging usually from 100ft. to 120ft. In the case of double-track roads, where the width of street permits, the tracks may be laid further apart than is usual, and poles planted between them. This is certainly by far the handsomest method of overhead construction. In the first place, it permits the use of only half the number of poles that would be necessary with the span-wire system, and it does away altogether with the necessity for span wires. The poles where this system is carried out may also be used for arc or incandescent lighting of the streets. The trolley wire is supported by brackets extending over the track on either side of the pole, and the feed-wires may be carried as usual on the poles, although an underground system of feeders is preferable. On suburban tramways running along country roads, the track is usually laid on one side of the road, and in that case a system of bracket suspension should always be carried out. If the line is single, the poles may be planted along the side of the track, and the trolley wire supported from single brackets, as in the case of centre-pole suspension.

Owing to the greater weight of the electric car, and to the fact that the power is applied to the wheels and not to a draw-bar, the permanent way, where electricity is used, must be of a more substantial character than is usually considered necessary in cases of animal traction. No girder-rail weighing less than 65lb. to the yard should ever be used. The necessity for absolute thoroughness in track construction cannot be too strongly expressed, for cheap and careless work here will entail, not only continual repairs to the track itself, but a rapid deterioration of the rolling-stock, and an increased coal bill. This fact is so evident that it would appear hardly necessary to refer to it, and yet there are scores of roads in operation to-day whose dividends are continually reduced by expenses traceable directly to faulty track construction.

A most important part of electric tramways is the thorough bonding of the rails, in order to secure a low resistance in the return circuit. In the first place, a supplementary return wire should in every case be laid along the track and efficiently connected to every length of rail throughout the road. The vast importance of this is not even to-day thoroughly recognised by very many tramway companies, but it is certain that any neglect in this direction will in every case mean undue loss of power on the line. No rule for track-wiring can be laid down that will suit every case, but in general it may be said that a wire at least as large as the trolley wire should be used to supplement the conductivity of the rails, and

* Paper read before the Royal Engineers.

that the latter should be efficiently grounded at several points throughout the line by means of copper or iron plates of large superficial area buried at points where they will be always in moist ground. The number of these grounds will depend largely upon local conditions, and upon the effectiveness of each. Advantage should be taken of every opportunity for connecting to gas or water pipes. The most important of these grounds is at the power station, and here too much care cannot be exercised. The cross-section of the wire connecting the track to the power station should be as great as that of all the feed-wires leaving the station. The chemistry of the soil must decide what is the best material to be used for bond wires, but in most cases copper, on account of its higher conductivity, is preferable. Experiments in some places have shown that galvanised iron is less liable to corrosion, but, where possible, copper should always be used, and should in every case be thoroughly tinned. The bond wires are firmly keyed to the rails in holes drilled for the purpose by means of channel pins, and also soldered strongly to the main track return. Several methods of bonding the rails have been used, but in any case good workmanship is of the utmost importance.

Turning now to the power station, we find certain indispensable features which were almost unknown in central stations until the advent of the electric car. The electric tramway may be said to be responsible for the high-speed power steam engine. It is important that the units of power in a generating station should be as large as is consistent with the safe operation of the road, and that each unit should be entirely independent of all the others. These requirements can best be met by the use of direct-belted engines, and there can be but little excuse for the employment of countershafting except in the case of enormous roads, where very large engines may be used, without a risk of a great percentage of the total power being disabled in the case of accident. In such cases large economical engines of the Corliss type belted to countershafting may advantageously be used. In the great West End power station at Boston, which, when completed, will have a maximum output capacity of 26,000 h.p., this plan has been adopted, and great economy secured by the use of 2,000-h.p. engines. The tendency, however, is towards the use of larger dynamos, and direct belting, or even direct coupling, at the cost of a sacrifice of weight efficiency, the economy of space effected thereby being an additional reason for the move in this direction.

The severity of the service imposed upon engines in tramway work, which is perhaps only equalled by certain work in rolling-mills, as well as the increased speed required for direct belting, necessitates extra heavy construction, bearings of greater size and length, and more ample flywheel capacity. The failure of builders to fully appreciate the conditions which the work imposed has been responsible for troubles, in many cases, which have tended to bring high speeds into disrepute. The excellent automatic engines that are now turned out by several manufacturers are, however, quite as reliable as other types, having been built especially for the work they are expected to do. Experience in every class of work has taught us the cost of poor steam engineering, and the tramway company which puts in inadequate apparatus will soon find itself in the interesting position of having to put up with exorbitant operating expenses, or else rebuild its entire plant. Where possible, and water can be had, compound condensing engines should always be used. There are very few places where coal is so cheap that 40 per cent. of the coal bill would not pay the interest on the difference in cost between compound condensing and single-cylinder engines.

Other things being equal, the tandem form of compound engines is to be preferred on account of its smaller number of moving parts. Where the cylinders are placed side by side, two sets of working parts are required, double the risk of breakage encountered, more oil used in lubrication, and more power expended in overcoming the friction in the engine itself. Another great point in favour of the tandem engine, especially in tramway work, is that on light loads, the low-pressure cylinder of the double engine, on account of the early cut-off, will receive comparatively little steam as exhaust from the high pressure. There will be, therefore, no compression in the low-pressure cylinder, and a pounding and loosening of all working parts will ensue. This difficulty is entirely avoided in the tandem engine, both pistons being on one rod, and the high-pressure always cushioned. The governor must be quick-acting and yet not too sensitive, and the variation in speed between no load and full load should be within 2 per cent. at the outside, and it is quite possible with engines operating at from 200 to 250 revolutions per minute to do even better than this. This close regulation can only be obtained by the allowance of very great flywheel capacity, and in some of the engines now built for tramway work the flywheels alone weigh nearly as much as the lighter engines of equal powers complete. With this class of engine, in which the driving wheels are from 6ft. to 7ft. in diameter for sizes of from 100 h.p. to 300 h.p., the engines and dynamos should be set not less than 20ft. apart between centres, and even somewhat greater distances than this are advisable where space is not of great importance. Jockey pulleys are an abomination, and tight belts, especially with varying loads, are a source of endless trouble, and besides this, the elasticity of long belts which can be run very loose is an aid to the governor, second only in importance to heavy flywheels. In calculating the steam power required, an allowance of 20 per cent. above the rated power of the dynamos should be made in order that a constant speed may be maintained under momentary excessive loads. On a properly-designed generating plant these unusual loads will not be of more than a few seconds duration, but it is a bad practice to have your engines constantly working up to their maximum capacity.

Of boilers little need be said. The opinions of engineers differ greatly as to which type is most suitable for tramway requirements, and examples of each class are found, showing under careful management an economy with which no fault can be found.

The question of generators is one that is closely allied to that of the engines, and in discussing the latter reference was made to the tendency towards larger machines which present tramway practice shows. It must be understood, however, that this applies only to the case of large installations, and must not be carried to such a point that an accident at the station will cause a shortage of power on the line. Reserve power in the generating station is of the utmost importance, and the units should be of such a size that this reserve can be economically provided. Many years' experience in direct-current incandescent lighting, which, as far as the generators are concerned, differs but little, except in the matter of voltage, from tramway work, has paved the way to the production of dynamos whose reliability seems to be all that can be desired. Future development will probably be in the direction of the production of larger slow-running multipolar machines which will lend themselves to direct coupling, but the generator of to-day is by far the most perfect feature of tramways installations. It is imperative for the satisfactory operation of the motors that a constant difference of potential should be maintained on the line under all conditions of load, and to this end the generators must be compound wound and perfectly self-regulating. An E.M.F. of 500 volts is universally used in the United States. It is desirable, in order to avoid carrying enormous currents, that the E.M.F. employed should be as high as practicable, and this figure has been adopted as well within the limit of safety. The arrangement of the switchboard should be such as to give the utmost flexibility in the operation of the station, and to allow the instant cutting out of any particular machine or the transfer of the load from one machine to another.

(To be continued.)

Rheumatism and Electricity.—Mr. Grigg, of 33, Eastbourne-terrace, W., has a medical institute where electricity is applied successfully, we are told, to the relief and cure of rheumatism, and we are in receipt of some testimonials there anent. Rheumatism is a dolorous and elusory complaint; let us hope electricity has some effect in dislodging this enemy of mankind.

SOME EXPERIMENTAL INVESTIGATIONS OF ALTERNATE CURRENTS.*

BY ALEXANDER SIEMENS.

(Concluded from page 189.)

As materials are important items in the cost of a transformer, the consideration of the first point shows the desirability of employing a strong induction. A similar conclusion will be drawn from the investigation of the relation between the induction and the drop of difference of potential in the secondary circuit of the series of transformers. As they are all supposed to give the same current, the drop from no load to full load will be in proportion to the resistance of the circuit. This resistance is in proportion to the weight of copper employed, as all the transformers are assumed to be wound with wire of the same diameter. The curve (8) giving the weight of copper at different inductions will therefore also indicate, in comparison with the normal transformer, the variation in the drop of potential between no load and full load under the same circumstances.

In order to determine the variation of the efficiency of the transformers under investigation, it is necessary to treat separately the losses in the iron and in the copper. The former can be found by the aid of the curves on Diagram I., in combination with the curve giving the weight of iron necessary at the various inductions. An example will best illustrate how this loss is ascertained in a case where the total mass of the iron is worked at the same induction, produced by a current of a frequency equal to 100 complete periods per second, the iron mass being composed of 1 mm. wires. The loss in the normal transformer working with an induction B = 5,000, and with a weight of iron = 1cwt., is 309·6 watts, according to Diagram I. For another transformer working with an induction B = 2,500, the weight of iron, as shown by the curve (7), has to be increased to 2cwt.; at the same time the loss per cwt. is reduced to 126·8 watts, or the total loss is reduced to 253·6 watts.

In a similar manner the losses for the different inductions have been calculated, and the results are embodied in a curve (9), which indicates that the loss of energy in the cores of transformers increases with the strength of induction, at first rapidly, but after the induction has reached a value of B = 1,000 the increase is very slow. As far as the loss of energy in the iron goes, it is therefore of not much consequence what induction between 1,000 and 5,000 lines per square centimetre is used. The influence of the strength of induction on the loss of energy in the copper can be shown in the simplest manner by comparing this loss in the normal transformers designed for 5,000 lines with the loss in the other transformers of the series.

There are evidently three possible cases for the normal transformer. The loss in the copper may be equal to the loss in the iron, or it may be greater, or it may be less. For each of these cases a curve can be plotted showing the sum of the losses in the iron and in the copper at the corresponding induction. If we take, for instance, the case that the losses in copper and in iron are equal, the total loss in the transformer having an induction B = 5,000, is 2 × 309·6 watts. For the transformer having an induction B = 2,500, the loss in the iron is given in our curve 9, and the loss in the copper is in proportion to its weight, which varies in accordance with curve 8, or in this particular case, the loss is = $\sqrt{2} \times 309{\cdot}6$ watts. In this way curve 11 has been plotted for the case of the losses being equal, curve 10 represents the case where the loss in the copper is equal to two-thirds of the loss in the iron, and curve 12 where the loss in the copper is 50 per cent. greater than the loss in the iron. Taking these curves to represent generally the variation of the total loss at the various inductions, it appears that, when keeping the loss in copper small in comparison with the loss in iron, it is quite possible to obtain about the same efficiency with any induction between 2,000 and 5,000 lines per square centimetre, but if a lower induction is used the efficiency, even on full load, decreases very rapidly. From the consideration of efficiency it is, therefore, desirable to work the transformer with a high induction, and it is only the question of the heating of the apparatus which imposes restrictions on the use of high inductions, to avoid the destruction of the insulating material. In other words, the problem was to find the maximum internal temperature of a body of known dimensions, when the rate at which its mass is heated has been determined.

In order to obtain some data towards the solution of this problem, a solenoid was constructed by winding 18lb. of insulated iron wire, 2·4 mm. in diameter, on a brass tube 300 mm. long, 8 mm. internal diameter, and provided with flanges at the ends each 100 mm. diameter. The internal temperature was measured by means of a thermometer just fitting the brass tube, and due care was taken to keep the temperature of the surrounding air constant during the experiments. A constant direct current was sent through the coil, and a reading of the thermometer was taken after it had ceased rising. The rate at which energy was supplied to the coil was determined by the product of the square of the current into the resistance of the coil, measured when the equilibrium of temperature had been attained.

By varying the current the internal temperature could be varied, and the results were plotted in curve 13, the abscissæ of which represent the cooling surface in square centimetres per watt dissipated, and the ordinates indicate the excess of the internal temperature of the coil over the temperature of the surrounding air in degrees centigrade, after the equilibrium between the supply and the dissipation of energy had been established in each case. This curve is a rectangular hyperbola of the equation, $xy = 1{,}500$, and it shows that if the temperature of such a coil is to be kept at 100deg. C., the cooling surface should be 15 square centimetres for each watt converted into heat in the coil. It is self-evident that this curve (13) relates only to the coil by the aid of which it was constructed, and that it can only serve as a guide under strictly similar circumstances. By way of comparison a set of experiments were made on the same lines with a cable transformer, hung up in air, six metres long and 9·5 cm. in diameter, the internal temperature of which was determined by means of a test wire, as described above. This curve (14) shows that for an internal temperature of 100deg. C a cooling surface of about 28 square centimetres has to be provided per watt of energy converted into heat in the transformer.

Before it is possible to draw general conclusions as to the connection between the internal temperature of transformers and their cooling surface, it is obviously necessary to make a good many more experiments in the direction indicated by the two curves just described. Last year Dr. Fleming read a paper before this Institution on "Some Effects of Alternating-Current Flow in Circuits having Capacity and Self-Induction" (*Journal* of the Institution of Electrical Engineers, vol. xx., No. 94, p. 374). It is, therefore, not necessary to repeat here the results of some experiments which were brought to the notice of the Institution at that time. A very important factor in the construction of alternate-current apparatus is the striking distance of these currents in various materials, as this determines, in the case of high-voltage currents, the thickness of the insulating material with which the conductors have to be surrounded, the ohmic resistance being no guide. The first set of these experiments referred to the striking distance in air. In all the experiments made the frequency of the alternate current was 100 complete periods per second, except where another frequency is specially mentioned, and the voltage was produced by means of an alternate-current machine and a transformer, and it was measured by one of Sir William Thomson's static voltmeters. The electrodes were repolished each time a spark had passed between them; one of them was fixed horizontally during the experiments, while the other could be advanced towards it from above by means of a micrometer screw which allowed of reading to a hundredth of a millimetre.

The experiments were made in the following manner: After connecting the electrodes of the spark micrometer to the terminals of the transformer, a certain voltage was put on and accurately measured; the distance between the electrodes was then slowly diminished until sparking occurred. Each experiment was repeated at least three times. Various electrodes were experimented with, the first pair being two plane parallel surfaces. In this case the fixed horizontal electrode consisted of a polished brass disc about 100 mm. in diameter, while the movable electrode was also formed by a brass disc, but only 37 mm. in diameter. To prevent the action of sharp edges, the edges of the discs were rounded off. The temperature of the surrounding air during these experiments was 14·75deg. C. The results obtained are as follows:

Difference of potential.	Striking distance.	Difference of potential.	Striking distance.
2,000 volts	0·67 mm	10,000 volts	4·80 mm.
4,000 ,,	1·59 ,,	12,000 ,,	6·46 ,,
6,000 ,,	2·53 ,,	15,000 ,,	10·23 ,,
8,000 ,,	3·60 ,,		

The last reading, giving the striking distance for 15,000 volts, cannot be correct, as the sparks started from the upper edge of the smaller disc, and not from the nearest points between the two discs, the smaller disc being placed above the fixed one. Curve 15 is the graphic representation of the above table.

For the next series the arrangements were the same as before, with the exception that the smaller movable disc was replaced by a half-sphere of 10 mm. diameter. The temperature of the air during these experiments was from 16deg. to 17deg. C., and its humidity 80 per cent.

Difference of potential.	Striking distance.	Difference of potential.	Striking distance.
2,000 volts	0·45 mm.	10,000 volts	4·37 mm.
4,000 ,,	1·40 ,,	12,000 ,,	5·65 ,,
6,000 ,,	2·30 ,,	14,000 ,,	7·32 ,,
8,000 ,,	3·25 ,,	15,000 ,,	9·02 ,,

These results are plotted in curve 16.

After this the movable electrode of the spark micrometer was replaced by a steel point of an angle of 60deg., its section being an equilateral triangle of 5 mm. sides. This point was also repolished after each spark; the spark, however, did not always start from the point. During these experiments the temperature of the air was 12deg. C., and its humidity about 50 per cent.

Difference of potential.	Striking distance.	Difference of potential.	Striking distance.
2,000 volts	0·40 mm.	10,000 volts	5 78 mm.
4,000 ,,	1·26 ,,	12,000 ,,	7·60 ,,
6,000 ,,	2·66 ,,	14,000 ,,	9·37 ,,
8,000 ,,	4·08 ,,	15,000 ,,	10·70 ,,

Curve 17 embodies this table.

After this the influence of an alteration in the frequency was tried by lowering this to 80 complete periods per second, and repeating some of the first experiments with disc electrodes. The striking distances for 4,000 volts and for 6,000 volts under these circumstances were found to be 1·47 mm. and 2·30 mm., or only slightly different from those produced by a frequency of 100 complete periods per second. From theoretical considerations it

* Paper read before the Institution of Electrical Engineers, February 11, 1892.

might have been expected that the distances would vary directly as the frequencies.

In order to investigate the influence of capacity, one or more coils of guttapercha-covered wire were connected to the circuit of the transformer in parallel with the spark micrometer. The first experiments were made with a frequency of 100 complete periods per second, the two disc electrodes, and a capacity of 0·113 microfarad. The temperature of the air was 16·5deg. C., and its humidity 79 per cent.

Potential difference.	Sparking distance. With capacity.	Sparking distance. Without capacity.
4,000 volts	1·53 mm.	1·59 mm.
6,000 ,,	2·21 ,,	2·53 ,,
10,000 ,,	4·17 ,,	4·50 ,,

A further experiment under similar conditions, but with a capacity of 0 28 microfarad in circuit, showed that the sparking distance at 10,000 volts was further reduced to 3·94 mm. These tests were repeated with other electrodes—viz., the spherical surface and the disc. At a difference of potential of 10,000 volts the sparking distance turned out to be:

1. With 0·14 mf. capacity in circuit .... 4·08 mm.
2. Without any ,, ,, ... 4·50 ,,
3. With 0·14 mf. ,, ,, ... 4·06 ,,

After that the steel point and the disc were used as electrodes, a capacity of 0·14 mf. being connected to the circuit, and the results were:

Difference of potential.	Sparking distance. Without.	Sparking distance. With capacity.
4,000 volts	1·26 mm.	1·14 mm.
10,000 ,,	5·78 ,,	4·83 ,,

All these experiments point to the fact that the sparking distances in air are diminished to a slight extent when capacity comes into play. With a view of ascertaining how the voltage is propagated along a circuit, the position of the micrometer relatively to the cable was varied.

The experiments detailed above were made with the spark micrometer connected to the beginning of the cable; they were afterwards repeated after inserting the spark micrometer in the middle of the cable, and again after it had been connected to the end of the cable. In all three positions the same striking distance was observed under similar circumstances, which tends to prove that the voltage is propagated uniformly over the whole length of conductor, even if there is capacity in some parts of the circuit.

As stated above, the voltage experimented with was measured by means of Sir William Thomson's static voltmeters; but it is undoubtedly the highest ordinate of the wave which causes the spark. This "real" voltage can be found, if sine waves are assumed, by multiplying the measured volts by $\sqrt{2}$, and these new figures should be applicable to constant continuous currents. In this way the results of curve 15 were corrected, and compared with some results published by Warren de la Rue in *Nature* on the 12th September, 1878. Assuming that the E M.F. of his cells was equal to 1·03 volts, and reducing his results to volts and millimetres, they compare as follows:

Difference of potential.	Striking distance. Warren de la Rue.	Striking distance. Siemens.
2,000 volts	0·45 mm.	0·25 mm.
4,000 ,,	0·95 ,,	0·80 ,,
6,000 ,,	1·55 ,,	1·45 ,,
8,000 ,,	2·15 ,,	2·15 ,,
10,000 ,,	2 85 ,,	2 85 ,,

On referring to the other curves published at the same time, it will be seen that Warren de la Rue found the sparking distances between two plane surfaces and between two spherical surfaces not to differ very much from each other. It may, therefore, be allowable to compare the mean values of these two curves of his with curve 16 for the sparking distance between a hemisphere and a plane surface after the values of the volts have been multiplied with $\sqrt{2}$.

Difference of potential.	Striking distance. Warren de la Rue.	Striking distance. Siemens.
2,000 volts	0·36 mm.	0·25 mm.
4,000 ,,	0·87 ,,	0·80 ,,
6,000 ,,	1·50 ,,	1·45 ,,
[illegible] ,,	2·10 ,,	2·16 ,,
10,000 ,,	2·75 ,,	2·85 ,,

Both these tables show that the results are practically identical, and consequently it may be concluded that the secondary current of the transformer used for the experiments is really a sine function.

Some further experiments were made with the same alternate-current machine and transformer, and a frequency of 100 complete periods per second, to determine the striking distance in various insulating materials. The differences of potential were again measured by Sir William Thomson's static voltmeter, or, in the case of the higher ones, by his volt balance. One series of experiments, represented by curve 18, was made by connecting the terminals of the transformer to the inner and outer conductor of concentric cables, the insulation of which consisted of impregnated fibrous material. The difference of potential was then gradually and slowly raised until the insulation gave way. Curve 18 really consists of two parts, the lower of which was obtained by breaking 35 short samples of cable, made with various thicknesses of the insulating material; the upper part, above 7,000 volts, was determined by breaking actual cables, not less than 50 yards in length, specially manufactured for these experiments.

The next series of experiments dealt with indiarubber insulation, but results proved to be extremely irregular, although a curve (19) has been plotted which gives the minimum voltage at which sparking occurred at the various thicknesses.

The following table gives the details of the samples tested, and under what voltage they broke down:

No.		Thickness of indiarubber.		
1.	40in. of 880 H wire	3·5 mm.,	broke with	21,500 volts.
2.	10 yds. of experimental core,	3·8 mm.	,, ,,	20,000 ,,
3.	1½ ,, ,, ,,	2·5 mm.	,, ,,	16,000 ,,
4.	1 ,, concentric cable..	3·5 mm.	,, ,,	28,000 ,,
5.	90 ,, No. 504 core	1·2 mm.	,, ,,	12,000 ,,
6.	46 ,, ,, 505 ,,	2·0 mm.	,, ,,	16,500 ,,
7.	50 ,, ,, 507 ,,	1·8 mm.	,, ,,	18,200 ,,
8.	48 ,, ,, 508 ,,	2·3 mm.	,, ,,	16,800 ,,
9.	5 ,, ,, 200 H	2·3 mm.	,, ,,	28,000 ,,
10.	1 ,, concentric cable.	2·0 mm.	,, ,,	17,500 ,,
11.	Indiarubber sheet	0·5 mm.	,, ,,	7,500 ,,
12.	,, ,,	1·0 mm.	,, ,,	10,500 ,,
13.	Experimental piece of core	10·0 mm.	,, ,,	38,000 ,,

The concentric cables were tested by connecting the transformer to the two conductors; the sheets were placed between the disc and the spherical electrode. The core, when in short lengths, was covered with tinfoil; when long, it was immersed in water; and the terminals of the transformer were connected, the one to the insulated conductor, the other to the water or the tinfoil respectively.

Another set of tests were made by placing calico on the disc of the spark micrometer, and by connecting the other pole to a copper brush, such as are used in dynamo machines, resting on the calico. Several samples of calico were tried: (*a*) thin calico, 0·12 mm. thick, not impregnated; (*b*) silesia calico, 0·15 mm. thick, not impregnated; (*c*) thick calico, 0·30 mm. thick, not impregnated; (*d*) thick calico, 0·30 mm. thick, impregnated. All four samples required the same lowest difference of potential—about 700 volts—for a breakdown. Different spots of the same sheet behaved very differently, some not breaking with even 1,000 volts; but at least one spot could always be found which broke down with 700 volts. Curve 20 gives the results obtained with several layers of the impregnated thick calico. The layers were tightly pressed together before being tested, and the points of the curve give the minimum value of the voltage which broke them down. The last curve (21) records the sparking distance through celluloid, which was tested in sheets placed between the two discs of the spark micrometer.

A good many of the high-tension experiments were made with a specially constructed powerful transformer, capable of giving at its secondary terminals a current of two amperes under a pressure of about 50,000 volts. This is now on view at the Crystal Palace Electrical Exhibition, and various experiments are shown to exhibit its qualities. Unfortunately, it is too heavy to be shown in this Institution.

In conclusion, it should be mentioned that all the experiments described in this communication were carried out at Woolwich, at the works of Messrs. Siemens Bros. and Co., mostly under the immediate care of Dr. Baur, who was freely assisted by the heads of the various departments whenever he encountered difficulties in the course of his work.

CABLE-LAYING AT TANGIER.

"To the late Sir William Kirby Green we are indebted for the electric cable that now connects Tangier with Europe," says the *Times* correspondent at Tangier in an interesting article on Morocco, "and the history of the laying of this cable is amusingly characteristic of Moorish stolidity. Having obtained a concession for the cable, Sir William was determined to have the work commenced, but the Sultan was just as determined it should not be laid. He first tried the plan so successful with his own officers, and offered the British Minister a large sum of money if he would undertake to have the cable cut when laid and not allow it to be replaced. He was no doubt astonished when the bribe was contemptuously refused, and then his Majesty tried the plan of taking no notice of Sir William's letters requesting permission to commence the work. After sending several respectful communications, and receiving no reply, the British Minister gave notice to the Sultan that on a certain day the work of laying the cable would commence, and accordingly this was done. Of course it was very soon cut, but this was a last expiring effort of obstruction, for a duplicate shore end is now sunk deep in the sand, and the Moors, as usual, submit to the inevitable. At Tangier, however, electric communication ceases, and behind that outlying port lies a vast region dark as night. When Sir W. Kirby Green had successfully laid the electric cable, the Spaniards, wishing to show that they also could do something for Morocco, got up a company to light Tangier by electricity; and hence you have the strange anomaly of the Soko, or large open market, with its sea of ankle-deep black mud, lighted throughout the whole length of its rough-paved causeway by the electric light. Extremes meet in this place; but, of course, the company cannot pay, as there are no rates or other municipal blessings in Tangier, and the Moors are not likely to pay voluntarily for what they do not want."

UTILISATION OF WATER POWER IN MADRAS.

It appears that on completion of the Periyar project there will be available near Madras, at Kuruvanuth, an enormous amount of water power, aggregating in all some 180,000 h.p. The *Madras Mail* has recently called attention to this fact, and indicated the possibility of serving Madras with light and power from this source. After alluding to the experiments in transmission of power from Lauffen to Frankfort, and the proposed transmission from Niagara to Chicago, it says: "If we can obtain the power for producing the electricity from waterfalls, where the circumstances are favourable to the regular and continuous generation of power, and if the nature of the country be such that the works necessary to utilise the power can be constructed for a moderate amount, then the electric light can be produced at a cost with which no other illuminant can compete. Moreover, the same currents which produce the light, may, like gas, be used for heating purposes or for the production of power. From a central station, therefore, electricity might be made to flow all over the country, distributing heat, power, and light.

"To return to the power available at Kuruvanuth on the completion of the Periyar project. Of the 180,000 h.p. which can be obtained on the turbine shafts, 162,000 might be obtained in the form of an electric current of 3,000 amperes and 40,000 volts difference of potential. By using suitable conductors, at least 50 per cent. of this power might be made available at any point within a radius of 400 miles, and we might therefore deliver not less than 80,000 e.h.p. in Madras. Such an enormous amount of power could not be utilised here, and we might throw off branches from the main trunk line to the towns of Periyakulam, Kodai-kanal, Madura, Trichonopoly, Tanjore, Kumbakonam, Negapatam, Cuddalore, Pondicherry, and Chingleput. In all these towns, and in Madras itself, the whole of the street lighting, and as much private lighting as could be obtained, might be undertaken, and then there would be a sufficient amount of power still left to replace every steam engine in the districts through which the mains would pass with an electromotor. Electric lighting would, however, only be required during a small part of the 24 hours of each day, and during the rest of the time this vast amount of power might be used for an immense variety of purposes. In Madras we might have electric tramways. In many places lift irrigation by electrically-driven pumps might be economically introduced, and electro-metallurgy, a branch of engineering as yet in its infancy, would undoubtedly absorb all the power that could be spared.

"Naturally such great results could not be obtained without an enormous capital expenditure, such as in this country there is little hope of ever being undertaken without the assistance of Government. In America a company has been formed to develop 125,000 h.p. at the Falls of Niagara, and that company has appointed a commission of eminent engineers and scientists to consider the question of how to best generate the power and transmit it to the places where it is wanted. Here, in Madras, we have 180,000 h.p. available under nearly as favourable circumstances, and we think it would fall within the sphere of the operations of the Government of this Presidency to appoint a somewhat similar commission to report on the best methods of generating and making use of the vast amount of water power which it is possible to obtain in Southern India. During the last 35 years 24,000 lakhs of rupees have been expended, either directly by the Government of India or by private companies under its guarantee, in the construction of railways. This has been necessary, because they are works of public utility which could not well be constructed by unaided private enterprise, and on the same grounds and for the same reasons we think it is time that attention was drawn to the immense advantages to be derived by the country at large for the utilisation of the natural forces at our disposal. The vast beds of iron ore might be utilised for the cheap manufacture of high-class iron by means of the water power at disposal. This will probably offer the best field for the first attempts at the utilisation of water power on a large scale."

ELECTRO-HARMONIC SOCIETY.

The next concert will be a ladies' night, on Friday, March 4th, 1892, at the St James's Hall Restaurant (Banquet room), Regent-street, W., at eight o'clock. Artistes: Vocalists, Mrs. Alex. Siemens, Mr. Ed. C. de Segundo, and Mr. Thos. Harrison. Solo instrumentalists: Piano, Mr. Alfred Izard and Mr. Ed. C. de Segundo; violin, Mr. T. E. Gatehouse. Orchestra: First violins, Miss Edith Doughty, Mr. Hewlett, and Mr. T. E. Gatehouse (principal); second violins, Mr Dunn, Mr. Thornton, and Mr. S. Richardson (principal); viola, Mr. H. Gibson; violoncellos, Mr. Waite and Mr. Roger le duc Bucknall (principal); contra basso, Mr. Brewer; piano, Mr. Alfred Izard; Mustel organ, Mr. H. M. Higgs. Accompanists, Mr. Alexander Siemens and Mr. Alfred Izard. Musical directors, Mr. T. E. Gatehouse and Mr. Alfred Izard. A Broadwood piano will be used. The Mustel organ kindly lent by Messrs. Metzler.

PROGRAMME.—PART I.

Overture	"Mirella"	Gounod.
	Orchestra.	
Song	"Be Silent, Love"	Lawrence Kellie.
	Mr T. H. Harrison.	
Song	"Weep you no more, sad fountains"	Somervel.
	Mrs Alex Siemens.	
Selection	"Minuet" from Handel's "Berenice"	Arranged by T. Best.
	Orchestra.	
Song	"Du Fragst mich Taglich"	E. Helmund.
	Mr. Ed. C. de Segundo.	
Organ Solo	"Extempore"	
	Mr. H. M. Higgs.	
Song	"Mary of Argyle"	
	Mrs. Alex Siemens.	
Intermezzo	"Cavalleria Rusticana"	Mascagni.
	Orchestra.	

PART II.

Overture	"Poet and Peasant"	Suppé.
	Orchestra.	
Song	"Der Nussbaum"	Schumann.
	Mrs. Alex. Siemens.	
Piano and Violin	"Kreutzer Sonata"	Beethoven.
	Mr. A. Izard and Mr T. E. Gatehouse.	
Song	"Hungarian Love Song"	Roeckel
	Mr. T. H. Harrison.	
Piano Solo	"Polonaise"	Chopin.
	Mr. Ed C. de Segundo.	
Song	"Die Mainacht"	Brahms.
	Mrs. Alex. Siemens.	
Valse	"Arabian Nights"	Strauss.
	Orchestra.	

PHYSICAL SOCIETY.—Feb. 12, 1892.

Annual general meeting, Prof. W. E. Ayrton, F.R.S., president, in the chair.

The report of the council was read by the **President**, as was also the obituary notices of Prof. W. Weber, late hon. member, Mr W. G. Gregory, and Prof. James Crouch Adams. A list of additions to the library accompanied the report.

Dr. E. Atkinson read the treasurer's statement, showing a gain of about £140. On the motion of the **President** the reports of the council and of the treasurer were unanimously adopted.

Prof. Van der Waals was elected an hon. member of the society.

Prof. Reinold proposed a cordial vote of thanks to the Lords of the Committee of Council on Education for the use of the rooms and apparatus in the Royal College of Science. This was seconded by **Prof. S. P. Thompson** and carried unanimously. A similar vote was accorded to the auditors, Dr. Fison and Mr. H. W. Elder, on the motion of **Mr. W. Baily**, seconded by **Dr C. V. Burton**.

The following gentlemen were declared duly elected to form the new council:—President: Prof. G. F. Fitzgerald, M.A., F.R.S. Vice-presidents: Prof. A. W. Rücker, M.A., F.R.S., Walter Baily, M.A., Prof. O. J. Lodge, D.Sc., F.R.S., Prof. S. P. Thompson, D.Sc., F.R.S. Secretaries: Prof. J. Perry, D.Sc., F.R.S., 31, Brunswick-square, W.C., and T. H. Blakesley, M.A., M.I.C.E., Royal Naval College, Greenwich. Treasurer: Dr. E. Atkinson, Portesbery Hill, Camberley, Surrey. Demonstrator: C. Vernon Boys, F.R.S., Physical Laboratory, South Kensington. Other members of council: Shelford Bidwell, M.A., LL.B., F.R.S., W. E. Sumpner, D.Sc., Major General E. R. Festing, R.E., F.R.S., J. Swinburne, Prof. J. V. Jones, M.A., Rev. F. J. Smith, M.A., Prof. W. Stroud, D.Sc., L. Fletcher, M.A., F.R.S., G. M. Whipple, D.Sc., James Wimshurst.

A vote of thanks to the officers of the society was proposed by **Mr. Swinburne**, seconded by **Mr. A. P. Trotter**, and carried unanimously.

The **Chairman** then invited suggestions towards improving the working of the society.

In response, **Prof. S. P. Thompson** said that as the society had been established 15 or 16 years, and had amply justified its existence, the time had now arrived for giving fuller recognition to the privileges of members. He thought they had earned the right to be called "Fellows," and that this ought to be signified by some distinctive title.

Mr. J. Swinburne suggested that before papers were brought before the meetings they should be read by a member of the council. If suitable, they should then be printed and proofs sent to members who applied for them. Mathematical papers could then be taken as read, and the discussions would be more interesting and to the point. It would also be an advantage if communications on kindred subjects could be taken the same day and discussed together. Papers on purely technical subjects should go to the technical societies.

Prof. Ayrton, in reply to Mr. Swinburne, said the members had the matter of papers in their own hands, for, as pointed out in the report of the council, if they would only send in the papers early enough, the secretaries would be glad to group them in the way suggested. Referring to Prof. Thompson's remarks, he said he had often thought it would be an advantage to have another class of members in the shape of "students," who should hold meetings amongst themselves.

Mr. A. P. Trotter said the society was unique in many respects, and thought it was not desirable to have different grades of membership.

Dr. C. V. Burton agreed with Mr. Trotter, and said that even if Prof. Thompson's suggestion was adopted means should be provided that persons could be admitted into the society without claiming any distinction therefrom.

Prof. S. P. Thompson, referring to the communications brought before the society, said it was not necessary that all should possess great novelty. Descriptions of new arrangements of apparatus, of diagrams, and exhibits of modern instruments were of great interest to members.

The **Chairman** pointed out that at the early meetings of the society exhibitions of instruments were frequent, and said the council would be glad if instrument makers would send apparatus to be shown at any of the meetings.

The meeting was resolved into an ordinary science meeting, and Messrs. W. R. Bower and E. Edsen were elected members; after which Prof. S. P. Thompson, F R.S., communicated a "**Note on Supplementary Colours.**"

THE NATIONAL TELEPHONE SERVICE.

The London Chamber of Commerce held a special general meeting on Monday at Botolph House, Eastcheap, to consider the state of the telephone service in the metropolis and elsewhere. Sir Albert Rollit, M.P., chairman of the council, presided.

The **Chairman**, in opening the meeting, said that despatch was an essential element of modern business; the saving in time being not only often the source of profit, but a chief means of cheapening production and distribution. The perfection of communication was of the greatest advantage to commercial classes, and it was clearly to their interest to carefully watch the telephone Bills now before Parliament. They should consider whether the fullest development had been given under existing conditions, and whether other nations obtained greater facilities, as his experience led him to believe. In America, for instance, long trunk lines are in general use; in France he had had the opportunity of speaking from Paris to Marseilles, and no communication could be clearer. If it be the fact that England is behindhand, we must seriously bethink ourselves of the cause. In steam and other engineering we have long been in advance of other nations, and we ought at least to be equal in telephone facilities to other countries. As to cost, there seemed room for a very considerable improvement. With regard to induction noises, no very great improvement over the original instrument was desirable, he thought; he had in his possession the second pair of telephones ever brought into this country, presented by his friend Prof. Graham Bell, and their enunciation was as good as any he had heard. He did not think that the difficulty with induction would be got over until a more general use was made of a second or return wire. This was a real necessity—it might add to the cost, but efficiency was the first consideration. Then there was the internal management of the operating staff—experience had shown abundantly that it was bad; latterly there had been some improvement, and persons' tempers had not been tried quite so much. With regard to the Bills before Parliament, the question was whether compulsory powers were to be given to private trading companies, or whether they should be exclusively under the Government State Departments. Experience with the Post Office had led one to conclude that wherever Government could be trusted to supply as good a service as private companies, there was a great advantage in so doing. If we could believe that the telephone service could be conducted in a thoroughly efficient manner, and not, as was the case in the Post Office, make the service primarily a source of revenue to the country, but to devote the profit to increase of efficiency, the performance of this duty should be undertaken by Government. An efficient telephone service was not only important directly in cheapening the cost of production, but indirectly in many branches of business. Electrical engineering was a branch which had by no means reached its limits; many industries were now dependent on electricity, and it should be noted that electrical work was now the most progressive branch of science in this country—it underlies every other trade. It is important the public should be educated and given the greatest improvements. This was to be done by technical education, but education would be of little use for persons working in the shops if one could not continually see progress in professional work. It was important to England, in this age of competition, to maintain itself at the head of the mechanical and scientific arts.

Mr. F. W. Reynolds moved a resolution, to the effect that the Chamber should appoint a deputation to apply for an interview with the Postmaster-General, and express the views of the Chamber as to the supreme importance of the Government bringing a Bill into Parliament dealing with the question of providing adequate facilities for telephonic development throughout the country. It was of extreme importance, he said, to use all the facilities possible at the present time, when we were severely handicapped in all the markets of the world. In many cases, also, it was not a question merely of cost but of quick despatch, as in cases which came before his own notice. Personally his experience with the telephone was good—his was a private line—but he heard constant complaints from his friends and customers.

The motion was seconded by **Mr. J. Martin**.

Mr. Jackson asked as to the scope of the Bills before Parliament.

Sir Albert Rollit read out the headings of the National Telephone Company's Bill: To open or run over any public road, erect posts, open or alter pipes, run lines over sewers or estuaries, place and repair posts on private grounds with compensation to owner, items as to compensation for ground taken, consent of local authorities, restitution of roads, restrictions as to impeding traffic, powers for stringing wires over private property, and so forth. The New Telephone Company's Bill was for powers to enter into and contract with authorities for running lines in, under, or over every street or railway, etc., and was more permissive and contractual in its character.

Mr. J. Chambers said he failed to see the object of appealing to the Postmaster-General. The two large companies had put their claims before the Chamber, and he considered the commercial world would be better served by private enterprise. He moved an amendment expressing an opinion that an efficient telephone service could not be given to the metropolis unless statutory powers were given to the companies.

Mr. Faithfull Begg seconded the amendment. The question resolved itself into whether the national telephone service should be carried out by the Post Office or by private enterprise. He could quite believe the time would come when the telephone service of the kingdom should be controlled by Government, but at present he believed it far better to leave it in the hands of private companies. Present evidence showed that, in spite of the fact that the Post Office had established telephone exchanges, they were left without any exchange of importance (excepting, perhaps, Newcastle, though he did not acknowledge this as really important) in the country, and not only so, but it has been beaten by private enterprise out of several towns. The fact was the genius of the Department was not able to deal with the exigencies, and it was not reasonable to leave it to the Postmaster to develop the industry. The National Telephone Company, he said, "had always carried economy on its banners"; it had commenced in the provinces, and had rapidly reduced the tariff to £10, with the exception of the metropolis, where the difficulties were so great—there was no other part of the civilised world where so many difficulties could be encountered. He agreed the powers should be hedged round, but if powers were granted to the electric lighting industry, why not to the telephone? He recommended the deputation to go straight to Government and press for powers for the private companies.

The **Duke of Marlborough** said that the question was one of enormous importance to the community at large. Very few really recognised yet what telephony actually was. We were accustomed to send down to the post office and send off our telegrams, or to ring up subscribers in our own town. But from Land's End to John O'Groats, any firm of importance, any subscriber to the ideal system, should be able to speak at once and in a few moments to any other person, be he in Birmingham, Glasgow, or Manchester, as one might speak into the next room. That is what telephony meant! He wished to put before the council this consideration—that they were members of the Empire and taxpayers, and, therefore, the real owners of the telegraph monopoly. If they allowed the telephone to cut out the telegraph—as it undoubtedly would eventually—what was going to happen? Did they wish to lose the immense sums of money invested in their telegraph service? This must be guarded against. The Post Office had natural possession of the underground lines, and had no need of extra facilities. He would suggest that the inter-town trunk lines should be in the hands of the Post Office. No Bill could give power to a private company as comprehensive as the Post Office already possessed, and it was the duty of the taxpayers to keep these powers in their hands. No doubt the Postmaster has put obstruction in the way year after year, but he thought he should be revealing no parliamentary confidence in saying that he knew that it was the intention of the Postmaster-General to bring in a Bill of his own. What the terms were he did not know further than that it would be a Government Bill to give facilities for underground telephone wires. Also, both the private Bills were to be opposed. He thought it would be unfortunate if these Bills were opposed before the second reading, as it would be to the interest of the public that evidence should be called in Committee, and it might be advisable for the Chamber to bring their influence to bear and secure this. He thought the laying and management of the telephone trunk lines should be in the hands of Government. As regarded distribution of the telephone messages, he thought this part might be left in the hands of private companies—if Government took over the trunk mains, and private companies did the actual exchange work, this he thought would prove the best for both taxpayers and private individuals. Parliament would never allow private companies to have general powers over the country—it was against all precedent and the feeling of Parliament. The electric lighting companies had no general powers of this kind, but were under one general Act vested in the Board of Trade. As regards tariff, no doubt £20 was too much; £12 would be sufficient, and this would allow a complete system of twin wires, which are absolutely necessary if a perfect system is to be secured. Further, a great difference must be made in the operating staff arrangements. With the present system in force in London many persons would sooner not speak at all. It should be perfectly possible to speak to six or seven persons in as many minutes. Still, bad as the present system was, it was extremely useful, and he recently had the instance of a patent agent who avowed the telephone was worth £1,200 a year to his business. He urged the importance of the first resolution that a definite expression of opinion should be obtained from the Postmaster-General, whether the Government is going to give powers to private companies is to bring in a Bill affording general powers.

Colonel Raynsford Jackson, chairman of the National Telephone Company, said that what his company wished to see was the granting of statutory powers under which the telephone companies

could do their work. They do not ask for special powers for themselves—the powers accorded to one should be accorded to all. The great difficulty in their way was that of way-leaves. The reason that the telephone was cheaper in other countries was simply that it could be worked cheaper. He had recently seen Berlin exchange, where they had 17,000 subscribers, while London only had half that number. The exchange there is in the hands of the Government, and no way-leaves are required. There are five exchanges with connections for 6,000 each, and about 3,500 are connected. The wires are run as the crow flies, and there are no royalties to pay. In England they are saddled with a 10 per cent. royalty; where a mile of wire would be sufficient they had to run 1½ miles. It cost them 30s. per subscriber for way-leaves, and the royalty came to £2 per subscriber, besides which they often had to encounter great cost in moving the wires to circuitous routes if way-leaves were not accorded or were stopped. They might reduce the subscription in London, but if they did, they would be unable to cope with the increased demand from difficulty with way-leaves, and they preferred to continue the high tariff—they simply could not connect up the additional wires. Reduction of tariff could only come about by accordance of fuller powers. They had now 22 exchanges scattered over a large area. These they have connected with twin wires, which lessens the sound. But it was only in last January, after two years' work, they had succeeded in connecting an adequate number of wires. The company recognised as well as anyone that metallic circuits are necessary, but could not obtain the facilities. They had long applied to the Commissioners of Sewers to allow them to put pipes underground, but had been refused. This would have enabled them to give twin wires at least to all the City subscribers, which embrace two-thirds of the whole number connected—a long way towards the complete metallic circuit. As soon as they received powers that was the work they would at once undertake. Even now they had done what they could, and Croydon, Sydenham, and part of Kensington has metallic circuits. It is not because they do not choose, but because they could not—they did the best they could under the circumstances. Still, as to the single wire, he would point out that it does its work excellently in many cases. All the exchanges in Austria, except that of Vienna, are on single wires; in Vienna they have double wires, because the Government has insisted on the wires being placed underground, and for underground service twin wires are a necessity. In France it is the same—all exchanges are on the single-wire system, except Paris, where wires are run in the sewers. With reference to the question of public or private enterprise, an example of the course of events was to be taken from Leicester, where the Post Office had 133 subscribers; when the National Company opened, the Post Office subscribers fell to 100 and the National had 275. In Hull they had more subscribers than the Post Office exchange, though it had been opened for 10 years. So far the single-wire system had shown itself adapted for places where one exchange was sufficient, where the wires are not of great lengths, and where they are not required to go underground. As to trunk mains, the National Company had now 20,000 miles of trunk mains over which they sent 1,600 millions of messages a year, at a cost of less than 1d. each. When it is advised that the trunk mains should be taken over by the Government it could be seen that such a proposal was of immense importance to the company, who, having taken the trouble, wished to reap the advantage. They would not agree to the taking over of the trunk mains alone—they would even rather the whole were taken.

Mr. Provand, M.P., chairman of the Mutual Telephone Company, said the Mutual exchange was opened in Manchester last February with a list of 100 subscribers. They had now 1,000 on the list, while the National Telephone Company had only 1,600—that is, in a few months they had obtained two-thirds as many subscribers as the National Company had obtained in 10 years. This was due to the better service and the lesser rates. The National tariff was £20, the Mutual tariff was £5 to shareholders (of whom there are 630), and £6 to non-shareholders. They had as many as 1,400 on their list, of whom 930 or nearly 1,000 were actually connected. When it was stated that the National Company kept the word economy on their banner it must have been in laying out money, not in tariff, that was meant. When Colonel Jackson had explained the high tariff as due to difficulties with way-leaves he must have been perfectly aware that there was another difficulty, far more important, which he had thought well to conceal, this was that the National Telephone Company had a very small amount of cash and an enormously large sum of paper capital. The work was done in London as bad as it could possibly be done. There was not a man on the Board of the old company that knew his business, and though the old company passed away there were still some of the old members on the present Board, and there was no one who could or would deal with the schemes from the use of the people. There were several very cogent reasons why the company could never be successful—the financial question was the principal one, and the other was that of twin wires. Notwithstanding what Colonel Jackson had said, there never would be a successful telephone service until twin wires were adopted throughout. Some towns might have a fairly serviceable system, but if any person wished to compare the two they could not do better than go to Manchester, where the two were working side by side. He would be glad to show deputations and let them test both the Mutual and the National, for he had them both in his office, and he did not hesitate to say which they would find by far the best.

Mr. Sheriff Foster, as a subscriber, said he hoped a better service would be the outcome of the meeting. He trusted that the National Telephone Company would not be allowed to absorb the new telephone company spoken of by the Duke of Marlborough. The way in which London subscribers were served was admitted by Colonel Jackson even to be very inefficient. They received the very minimum of service for the very maximum of cost.

Mr. Sydney Morse urged that Parliament should allow the Bills to go into Committee as suggested by the Duke of Marlborough. He thought restrictions should be enforced to prevent exorbitant tariffs being levied, and that conditions should be inserted to prevent the telephone companies laying further claim (as they did now) to a monopoly of the earth as a return. He suggested the two resolutions should be amalgamated.

The **Chairman** said that this was exactly what he was intending to propose.

The resolution as amended was then passed unanimously as follows:

"That, in view of the importance of the telephone industry, and the fact that two separate companies have Bills before Parliament, this Chamber should appoint a deputation to apply for an interview with the Postmaster-General, and express the views of the Chamber as to the supreme importance of her Majesty's Government bringing a General Powers Bill into Parliament, so as to afford facilities for the development of the telephone not only in the metropolis, but also with regard to inter-town service all over the country, whether by private companies or by the Government itself."

The following names were handed in to be submitted to the council of the Chamber of Commerce as a deputation: Sir Albert Rollit, M.P., the Duke of Marlborough, Mr. Provand, M.P., Mr. F. W. Reynolds, Mr. Chambers, Mr. Bennett, Colonel Jackson, Mr. Faithfull Begg, Mr. Jackson, Mr. Sheriff Foster, and Mr. Sydney Morse.

In the course of the meeting Mr. Wallace announced that the recently formed Association of Telephone Users would be registered as a public body with members at 5s. a year, having thus a *locus standi* in all questions of Bills before Parliament, and he urged members and subscribers to join this association.

COMPANIES' MEETINGS.

WESTMINSTER ELECTRIC SUPPLY CORPORATION.

The ordinary general meeting of the shareholders of this Company was held at the Westminster Palace Hotel on Wednesday, Lord Suffield, chairman, presiding.

The **Secretary**, Mr. Frank Iago, having read the notice convening the meeting,

The **Chairman** then said that he was not yet sufficiently recovered from a severe illness to address them, but perhaps they would allow him to move the adoption of the report and accounts in a formal manner. He would ask his friend Mr. Powell to do his (the Chairman's) duty for him on this occasion.

Mr. J. H. Powell, before proceeding to make any remarks on the report and accounts, expressed the wishes of the Board and of all the shareholders present that the Chairman might be restored to health. They had been greatly pained by the news of his long-continued illness, and hoped now that he had come among them again he might become as strong as ever he had been. The report having been taken as read, the speaker continued: We have now the pleasure of congratulating you upon the possession of three central stations, one in Millbank-street, which is practically complete—in fact, I don't think that any more payments will have to be made with regard to it, except for some condensing apparatus. Then we have a central station at Eccleston-place, which, so far as plant and works are concerned, is almost complete. And then we have, further, the station at Davies-street, which is in an almost similar state. At Eccleston-place we are making provision for offices for the Company, offices for the secretary, for the engineer and his assistants, and a Board-room. The erection of these buildings will be completed for an amount the interest upon which will be very considerably less than the rental we are paying for somewhat inconvenient premises in Victoria-street. At Davies-street we are covering the frontage with flats or chambers erected at no very large cost, and we expect a very considerable rental from them. The buildings have all been put up in the most substantial way, and I hope any shareholders who have the opportunity will go and see for themselves how we have combined the very best construction, without being at all extravagant. I think you will all say if you see these buildings that they are an ornament to the neighbourhood in which they are, and I believe they will be surrounded by buildings of a similar character. The greatest care has been taken by our engineer to put up machinery of the best description, at the least possible cost, and which, moreover, I believe to be the most economical. But we have arrived at this result after a great many drawbacks. In the first place, our architect tells me that we were delayed at least 66 days by the severe frost of 1891; and, moreover, the carpenters' strike of that year delayed the Davies-street buildings at least six months. Yet, notwithstanding these great drawbacks, the promise which we held out to you at our last general meeting that we should be able to work from Eccleston-place within about a fortnight, was fulfilled almost to the letter. Within a week of our meeting we were able to start Eccleston-place—that is, by the 2nd March—and on the 4th March we were able to supply light for her Majesty's Drawing-room with as much perfection, I believe, as characterises any of our lighting. Then I must tell you that at the end of February of last year we had only 13,148 lamps on circuit, and to show how the electric current was wanted, we

found that in March there was an increase of 5,842 lamps; in April, 9,992; in May, 6,789; in round numbers about 22,000 lamps. That is, an *increase* of 22,000 lamps over and above the small number we were supplying at the end of February, which was only 13,148. Then by the end of June we were supplying about 37,000 lamps; that was, in round numbers, about three times what we had been supplying in February. But when June came sunlight was beginning to take the place of electricity. People were beginning to leave town residences, and, notwithstanding the great increase in our lamps, we found that our revenue did not increase in a like proportion. However, the increase of lamps still went on. In June we had an increase of 1,500 odd, in July 2,700 odd, August 2,500, and then as the days got shorter the increase became larger still—4,900 (Sept.). Altogether in these four months we made an increase of 11,692 lamps, which I think was very gratifying under the circumstances. We found, however, that there was no increase of revenue. The light of the sun kept on and people kept away, and it was not until October that we began to realise the great increase that we had made in our business; while it was not until December that we found that fog was our best friend, as I believe it always will prove to be. Towards the end of December our receipts in one week rose from £800 to £1,200—that is, an increase of 50 per cent. Of course this put a very heavy strain upon our engineer, and all who worked under him, and I am happy to say that the supply in that week was as good as it had ever been. It is still more gratifying for me to say, that when the following week came and the receipts for light at once fell down from £1,200 to their normal state of £800, the expenses seemed to decrease almost automatically. The figures I have given you will explain why the income we show on Dec. 31 is so small—viz., because during the first part of the year we had comparatively few lights, and it was only as the season went on that the great increase took place. Again, it was only in November and December we showed what a valuable business we had. It will be interesting for you to know what is likely to be our income from our present circuit of lamps. I take our present number at the very low figure of 68,000. I may tell you that since December 31 the number of lamps lighted has very largely increased, and that we have now arrived at the figure of 75,253. But I will take the very moderate number of 68,000, and the still more moderate estimate of 10s. per lamp and that will show you that we should have an annual income of £34,000, instead of the comparatively small income which is shown in our published accounts. These accounts give our income as £19,000, so that upon a lamp circuit of 68,000, we shall have an increase in revenue of £15,000. But then, of course, these figures are very far within the mark. We find now that the increase in applications for light per month amounts to something like 4,000 lamps, and we see no reason why this figure should be less, although we can hardly expect that we shall gain the enormous increases this year that were shown during the past year. I am quite satisfied of this: if we supply a good light at a moderate price people will see that electric lighting has become one of the necessities of the age; that it is necessary for people's comfort in their houses, and also most necessary for the conduct of business. In my own very small experience I have occasionally to go to hotels, and I always choose those which have the electric light. I find that it is the best light, that it gives the least unpleasant heat and no unpleasant fumes, and I take it that every hotel and every clubhouse will within a very short time be obliged to avail themselves of the light which we offer them. Now I must again recall to your minds the very great disadvantages under which we have laid during the past year. Anyone who had gone to Davies-street station about this time last year would have said that it was utterly impossible that we could have supplied electric light from that station for several months. Everything was in the greatest confusion. We had an enormous number of excavators, builders, bricklayers and labourers at work, and you know, from your own experience in private houses, the dust these gentlemen make about them, and how destructive that dust is to machinery. Notwithstanding this, when we saw the business that was offered us (the very large business shown in our monthly increases) we thought it was wise in your interests to put up a temporary building and to work this business at any reasonable cost. The cost, I confess, was great, but I think that the advantages are far out of proportion to the cost of producing the light. Having so far descanted upon what has taken place, and what are your probable requirements, it may naturally occur to many of you to ask me, "What provision have you made for the future?" I think I can tell you tolerably accurately. We are supplying about 68,000 lamps from our present premises, and we find that with our existing machinery, either in place or on order, we have accommodation for about 130,000 lamps. If the space at our disposal within the existing buildings were utilised, we could supply from Millbank-street 30,000 more lamps, Eccleston-place 60,000 more lamps, and Davies-street 75,000 more lamps, so that altogether the existing premises could supply 165,000 more lamps. That brings up our capability of supply to 295,000 lamps which I will take to be, in round numbers, about four times our present output; but that is not the measure of what we can do. We find that at Eccleston-place we have a very considerable space in addition, so that when the time comes we shall be able to enlarge our buildings there, and to some extent at Millbank-street also, so as to arrive at a still larger increase—altogether, with our extra space, we shall be able to supply about double the figure that I have mentioned (295,000). This is, I think, very satisfactory. I may tell you, in passing, that at Eccleston-place we shall probably have to put up a little more machinery to accommodate the extra number of lamps, and I think it is not unlikely that we shall have to work that station tolerably hard when we get to the end of our tether; because I take it that the time must come, if Mayfair goes on as it has already begun, when we shall have to provide further accommodation in that district. I won't go on with these observations any further, but I will take you to something which is more immediately pressing, and that is the amount which we shall have to allow for depreciation of machinery. You will see that in these accounts we have allowed £1,000, which we consider to be both fair and ample. Our machinery is new, and a great deal of it was not thoroughly worked until towards the end of the year, and therefore, although everything wears as soon as it is put into work, we ourselves among the number, yet we thought it was only right that we should put a certain sum against depreciation of machinery. But I must not deceive you by letting you suppose that £1,000 will in any way be sufficient for the depreciation which we are likely to set against our revenue, and upon this matter I will quote a report of our engineer, which I believe you may thoroughly rely on. He says: "I think it would be wise not to allow less than £100 a week to be set apart for depreciation, paying all maintenance charges out of revenue, in order that the Corporation may be able to meet the possibility of some new invention or improvement being so rapidly matured as to make some of our machinery obsolete." In passing, I may say that our machinery is of the best and newest description, but electric lighting being a new invention there is no knowing what developments may take place, and so I quite agree with our engineer. I ought not to say that I agree with him because I am no one and he is everybody, but I thoroughly confirm all that he says in this matter. The speaker then continued his reading of the engineer's report, as follows: "So far as we at present know there is no astounding economy to be made in the cost of production of electric light. Economies in detail will, of course, be effected, and the cost of production will be reduced as the total output increases. But any economies at present must be the straightforward results of thorough good management and unremitting attention to details. If some happy inventor succeeds in showing us how to provide light by electricity without producing heat, there will be an enormous saving at once. Many inventors have been at work at this for a long time, but as yet they have not attained any results, so far as I know, of any commercial importance. No one can deny that within a reasonable number of years some such discovery may be made, although at present the very best work that has been done does not seem to have pointed out to us the right path. It is right to remember, however, that steam boilers, engines, mains, dynamos, etc., will be required whatever system may be the system of the future, and although in all probability dynamos different from those at present in use will be required, the rest of the plant may quite possibly remain unaltered. In any case, the change of dynamos would be common to every supply company, and not peculiar to one, so that we should be still in quite as good a position as any company." These figures, £100 a week, have not been adopted by the Board, but I may say that we have such very great confidence in Prof. Kennedy's figures, that I do not doubt we shall see the wisdom of adopting them and the policy which he recommends. The tax on the energies of the Board during the construction of the works has been very heavy, and it is no small credit to those who started this Company—of whom I was not one—that they so accurately calculated the requirements of the districts. They said that it would require £300,000 to start this business, and we have managed to keep within that mark for the districts that were allotted to us. But I should not be doing my duty if I were to claim for myself, and I am sure my colleagues would not wish for a moment to take credit to the Board for the results that I have put before you—they are mainly produced by the foresight, the constructive power, and the unfailing energy of our superintendent engineer (Prof. Kennedy). It would be wrong of me to attempt to take credit for anything of this kind, unless I put his name prominently before you. He has always kept his work well within his estimates. Not only have I been struck by his accuracy in figures and his power of design, but also by his readiness to take advantage of every appliance which has been invented to reduce the cost of working, and I should say that no company has carried out similar works at a less cost or with greater success. I believe that no company within two years of its active existence has been able to supply the public with so many lights, or so well, and for that result you should in a great measure thank Prof. Kennedy. I must also single out your architect (Mr. C. S. Peach) for much praise. He has evidently entered into the spirit which has throughout animated the Board. He has worked well and cordially with Prof. Kennedy, and in every dispute that we have had—and people carrying on large buildings cannot avoid disputes—with adjoining owners, he has not only kept us free from litigation, but with the help of the common sense he always carries about with him has succeeded in making good settlements for us. I must also say words of praise in favour of Captain Bax and our whole staff. Captain Bax has been most successful in getting customers and dealing with them after we had obtained them, and now that our business is likely to be one more concerning administration than construction, I believe that he will cordially work with us and will be a great helping hand towards carrying out the policy which Prof. Kennedy has put forth in the report which I have read to you. (He then pointed out a diagram on the wall, on which different coloured lines represented the number of lamps installed, the amount of revenue, and cost of production, pointing out that the line representing revenue bore out what he had said—viz., how during the summer months the revenue ran down and the expenses were slowly climbing up, but how matters were righted when the short days and fogs came on.) Continuing, the speaker

said: I have only one or two remarks to make on this chiefly in answer to a shareholder who has written to the Secretary, and who wished me to answer the question at the meeting. The question was, "How is it that our cost of generating electricity appears to be so high in comparison with the cost of another company?" The reason is that that other company began with a good business at the beginning of 1891, and that we, as you will see from that diagram, had hardly any business at all. But during the whole of the year we were obliged to have an engineering staff to do the small business, and it was not until we had reached September or October that we actually paid our working expenses. It could not be otherwise. We had three stations, we had three resident engineers, and a number of people about us that we could not possibly discharge—in fact, we could not carry on the business without them—and therefore the cost of generating the electricity appears to be comparatively high. But if you will go into details I think you will find that our cost is quite as low as the other company's, and that the explanation I have given you is ample for the purpose. I will conclude my remarks by seconding the adoption of the report, and beg to say that if any gentleman here requires any explanation of the accounts or the report, my colleagues and I will be most happy to give it.

A question put by **Mr. Wm. Cooper** as to the issue of £30,000 in debentures having been answered and proved to rest on a misapprehension, due to absence abroad,

Mr. Fitch, the writer of the letter alluded to by the Deputy-Chairman, said that he drew attention particularly to the coal expenditure, which was proportionately £700 more than another company. He also alluded to the cost of oil, waste, and water, which was between £300 and £400 more than in the other company.

Prof. Kennedy, at the request of the Chairman, answered this question. He said that at the time of year when they were working by no means economically—viz., at the beginning of the year—they had a temporary station at Davies-street, which was using 50 per cent. more coal per unit than was used now. When they were first started, the stations at Davies-street and Eccleston-place were using more coal proportionately than was the case now. The questioner was comparing the work of the Company with 10,000 lamps going in January, with the work of a company beginning with 30,000 lamps at the same time. He had been through the accounts very carefully, and the cost in pence for the last two quarters, when they had had a considerable number of lights on, had been precisely that of the company alluded to by Mr. Fitch, and the total sum paid by them and by the Westminster Company per unit was about the same. The cost of stores, water, and oil was a little less with the Westminster than with the other company. He trusted that next year they would be the most economical of all the companies. There was no fair comparison between a year in which they had been working upwards under difficulties, like last year, and a year such as they were now beginning with a fairly full load on.

The **Chairman** then put the motion adopting the report and accounts, and it was carried unanimously.

A **Shareholder** asked as to the prospect of a dividend.

Mr. Powell said they had not discussed the matter. They dealt with facts and not with prophecies, and would rather wait and see the result of the next six months' working. As soon as it was possible to declare a dividend they would do so.

The **Chairman** concurred, remarking that he thought the honourable proprietor would see that they were in a fair way to success.

Mr. Reed proposed the re-election of Messrs. Cooper Bros. and Co. as auditors. This was duly seconded, and carried.

Prof. Kennedy invited shareholders to go over the Company's stations, as he was sure they would be interested in what they saw there.

A vote of thanks to the Chairman for presiding under exceptional difficulties, and to the Board, was heartily accorded on the proposition of **Mr. Mark Stewart, M.P.**, seconded by **Mr. Cooper**, and the proceedings closed.

BIRMINGHAM ELECTRIC SUPPLY COMPANY.

The second annual meeting of this Company was held on Thursday week at the offices of Company. Mr. H. Buckley presided.

The **Chairman**, in moving the adoption of the report (see *E.E.* for February 12th), said the close of the financial year was altered from the 31st March to the 31st December to meet the requirements of the Board of Trade. The accounts showed a profit of £713. 16s. 4d.; but although the number of lights on the 31st December was 5,480, that was not the number of lamps earning an income during the nine months. The average number of lamps was 3,135, or, in other words, the earning power of the 5,480 lamps was only for 5·15 months. They commenced in April with 795 lamps only, but that number increased to 5,192 lamps earning an income, although there were 5,480 on order. At the present time there were more than 6,100 lamps on order. The current had been taken by various classes of the community, including hotels, clubs, public buildings, institutions, restaurants, shops, banks, insurance offices, general offices, and a theatre. The demand for the light had been most satisfactory, and during the coming year it would be necessary to extend their mains and make some increase in their engines and dynamos in order to be prepared for an extension of their business, and to meet any temporary difficulty which might occur through their plant getting out of repair.

Mr. C. A. Harrison seconded the resolution, which was carried.

Messrs. J. F. Albright and G. H. Johnstone were re-elected directors, and Messrs. Sharp, Parsons, and Co. auditors.

INDIA RUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY.

The twenty-eighth ordinary general meeting of this Company was held at Cannon-street Hotel on Tuesday, Mr. S. William Silver, chairman, presiding.

The **Secretary**, Mr. Wm. J. Tyler, having read the notice convening the meeting,

The **Chairman** moved the adoption of the report and accounts, together with the declaration of a dividend and bonus for the year at the rate of 12½ per cent. The amount carried forward was, he said, £42,073, after adding £25,000 to reserve. He wished to impress upon shareholders the fact that the amount of their share capital was very small when they considered the nature and extent of their business. By looking at the accounts (*vide* last issue of the *Electrical Engineer*) they would see that the first item of their "assets and expenditure" was £70,000 more than the whole of their subscribed share capital, and yet some shareholders did not see the advantage of their reserve fund. But it was necessary. In fact, the working capital, with the reserve added, was too small to enable them to undertake extensive contracts when offered. They must remember that cable contracts were generally large ones; and when two or three came to be open for tender about the same time, contractors needed a large command of capital to deal with them. Taking all these facts into consideration, the Directors thought the time had come for them to set to work to still further increase their capital, and their present intention was to issue some new shares. They would, of course, issue them at a premium, and they proposed to offer them to shareholders in proportion to their holdings, so as to give to each one an advantageous opportunity of increasing his stake in the Company. Machinery and buildings, both in this country and in France, were now so complete as to put the Company in a very favourable position as manufacturers. Their prospects, also, he would add, were very encouraging. It was his painful duty to inform shareholders of the death only last week of his old and esteemed colleague, Mr. Neil Bannatyne.

Mr. Abraham Scott having seconded the motion for the adoption of the report,

The **Chairman** invited remarks from any shareholder who might feel in a questioning humour.

Mr. Cochrane was not struck with the brilliancy of the return to shareholders in view of the fact that Directors were handling a reserve fund fully equal to three-fourths of the capital on which dividends were paid—viz., £416,000. He proceeded to criticise the remuneration of the Directors.

Mr. Swete alluded to the way the reserve fund was invested, a subject on which he wanted more information, and also to the remuneration of the Directors, and thought it would be better to make it a fixed sum (at present the Directors receive additional remuneration when the shareholders have received 10 per cent.).

The **Chairman** did not think Mr. Cochrane's general remarks called for any reply. In answer to Mr. Swete, however, he would point out that the way the reserve fund was invested was clearly stated in the assets as being in premises and stock. He then put the motion, which was carried unanimously.

The re-election of Mr. Abraham Scott and Mr. A. Weston Jarvis, M.P., as directors, was proposed by the **Chairman** seconded by **Mr. Marsham**, and carried *nem. dis.*

Mr. Weise having been re-elected auditor, on the proposition of **Mr. Hanson**, seconded by **Mr. Cochrane**,

The proceedings closed with a cordial vote of thanks to the Chairman and Directors, the name of Mr. Matthew Gray, managing director, being specially mentioned.

COMPANIES' REPORTS.

TELEGRAPH CONSTRUCTION AND MAINTENANCE COMPANY.

The report of the Directors for the year 1891 states that the accounts for the year show a net profit of £85,199, after charging the interest on the debentures. To this sum must be added £61,524 brought forward from last year, making a total of £146,724. From this amount is deducted the interim dividend of 5 per cent., paid July 14, 1891, amounting to £22,410, leaving £124,314 to be dealt with. Of this sum the Directors propose to distribute a dividend of £1. 16s. per share, absorbing £67,230, being at the rate of 15 per cent., and making, with the amount already paid, a total dividend for the year of £2. 8s. per share, or 20 per cent., free of income tax, leaving £57,084 to be carried forward to the next account.

NEW COMPANIES REGISTERED.

Electro-Automatic Fire-Extinguishing Company, Limited.—Registered by Fox and Joy, 59 and 60, Chancery-lane, W.C., with a capital of £12,500 in £1 shares. Object: to carry into effect an agreement, expressed to be made between Charles M. Martin (of No. 8, Imperial-buildings, Holborn Viaduct) of the one part and this Company of the other part, for the acquisition of certain letters patent, patent rights, etc., and to develop and work the same, and to carry on in all its branches the business of a manu-

facturer and vendor of fire-extinguishing apparatus. Registered without articles of association.

BUSINESS NOTES.

City and South London Railway.—The receipts for the week ending 21st February were £827, against £718 for the corresponding period of last year, showing an increase of £154. As compared with the week ending February 7th, last week's receipts show a decrease of £54.

Direct Spanish Telegraph Company.—The Directors have to recommend the payment of a dividend of 10 per cent. per annum on the preference shares, and of 4 per cent. on the ordinary shares, making, with the previous half-year's dividend, a total distribution of $4\frac{1}{2}$ per cent. for the year on the ordinary shares.

Electric Traction.—In connection with another note in this column, we are informed that Mr. W. S. Graff-Baker, who has been the representative of the Thomson-Houston International Electric Company's electric traction system in Great Britain, will continue to devote himself exclusively to the introduction of the system, with headquarters at the Company's offices, 35, Parliament-street, Westminster.

The Thomson-Houston System.—The Thomson-Houston International Electric Company, of 35, Parliament-street, S.W., inform us that they have just transferred all their business in Germany, Austro-Hungary, European and Asiatic Russia, Finland, Sweden, Norway, Denmark, Holland, Belgium, Switzerland, Turkey and the Balkan States, connected with the introduction and use of the Thomson-Houston systems of electric lighting, power, tramways and mining apparatus, to the Union Electricitäts Gesellschaft, of Berlin. The manager hitherto of the Hamburg office of the Thomson-Houston International Electric Company, Mr. Louis J. Magee, will take an active part in the management of the new company, as its technical director. All business in Europe, in countries other than those named, remains under the direct management of the Thomson-Houston International Electric Company, and will be cared for from the general European office of the Company, No. 7, Rue du Louvre, Paris, where a competent staff of engineers will be kept, and from which office all information and estimates will be cheerfully furnished. Mr. E. Thurnauer, who for several years has been in charge of the Paris office of the Thomson-Houston International Electric Company, has been appointed by the Board of Directors the general European manager of the Company, and will have sole charge of all its affairs in Continental Europe, Great Britain, and Ireland. The London office of the Company will remain at 35, Parliament-street, Westminster, S.W., although the lighting business for England and Ireland will be conducted by its long time agents, the Laing, Wharton, and Down Construction Syndicate, Limited, of 38, Parliament-street, S.W.

PROVISIONAL PATENTS, 1892.

FEBRUARY 15.

2913. **Improvements in the electrometallurgic extraction of zinc.** George Nahnsen, 38, Alexander-strasse, Berlin. (Complete specification.)

FEBRUARY 16.

2981 **Improvements in electro-medical appliances.** Percy Albert Craven, 9, King's-road, Wimbledon, Surrey.

2992. **Improvements in systems of electrical distribution of heating currents.** George Dexter Burton, 52, Chancery-lane, London. (Complete specification.)

2996. **An improvement in the construction of electric incandescent lamps.** Frederick Hoyer, 1, Maghill-street, Liverpool.

030. **Improvements in and relating to the lighting of railway vehicles by electricity, and to apparatus therefor.** Henry Harris Lake, 45, Southampton-buildings, London. (The Consolidated Car-heating Company, United States.) (Complete specification.)

FEBRUARY 17.

3112. **Improvements in electric meters.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London.

3113. **Improvements in generating, transmitting, and utilising currents of high tension, and in apparatus used for these purposes.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London.

3114. **Improvements in electrical primary batteries.** Charles Thompson, 18, Buckingham-street, Strand, London.

3120. **Improvements relating to galvano-plastics or the electro-deposition of metal** Pierre Henry Bertrand, 4, South-street, Finsbury, London.

FEBRUARY 18.

3145. **Improvements in electric globe and shade holders.** John Whitehead, 42, Anglesey-street, Lozells, Birmingham.

3161. ***Indicator of railway stations by electricity.*** *Julius Heinrich Ahrens, 100, Belsize-road, Swiss Cottage, London.*

3211. **An improved electric switch.** Frederick Brown, 37, Chancery-lane, London.

3212. **Improvements in the application of electric light to roundabouts, and the like, which improvements are also applicable to advertising purposes.** Frederick Brown and Patrick Collins, 37, Chancery-lane, London.

FEBRUARY 19.

3223. **Improvements in apparatus for electrically signalling the engine-drivers or the guards of trains.** George Wilson, Bank-buildings, George-street, Sheffield.

3233. **Improvements in apparatus to be used in connection with electrically-driven machines.** William Stepney Rawson, Charles Scott Snell, and Woodhouse and Rawson, United, Limited, 88, Queen Victoria-street, London.

3234. **Improvements in electrical switches suitable for use in connection with electric launches and the like.** Charles Scott Snell, and Woodhouse and Rawson, United, Limited, 88, Queen Victoria-street, London.

3238. **A gear spring lock action for glass holders of globes used on chandeliers, brackets, electroliers, etc.** Henry Bisseker, 11, New Bartholomew-street, Birmingham.

3240. **Improvements in materials or compounds to be used in the manufacture of moulded articles, such as door handles, insulaters for electrical purposes, boxes, toys, and other articles of the like kind.** James Lang, 35, Southampton-buildings, London.

3244. **Improvements in the method of and apparatus for lighting by electricity circular switchback railways.** William Mitchell, 8, Quality-court, London.

3283. **Improvements in electric arc lamps, specially applicable to search-lights.** John Henry Tonge, and Latimer Clark, Muirhead, and Co., Limited, 24, Southampton-buildings, London.

3291. **Improvements in tubular electrical conductors.** Ernest Payne, 28, Southampton-buildings, London.

3297. **Improvements in electric meters.** Caesar Vogt, 38, 38, Chancery-lane, London.

3300. **Improved means for effecting the connection of electrical conductors.** Clement Johnson Barley, 47, Lincoln's-inn-fields, London.

FEBRUARY 20.

3314. **Improvements in, and relating to, the utilisation of alternating currents of electricity for producing motive power, for charging storage batteries, and for other electro-mechanical and electro-chemical operations.** Charles Barnard Burdon, 71, Raleigh-road, Hornsey, Middlesex.

3366. **Improvements in dynamo-electric machines.** Thomas Lynch Hemming, 12, Cherry-street, Birmingham.

3379. **Improvements in stoves applicable especially to thermo-electric stoves.** William Robert Renshaw, 24, Southampton-buildings, London.

SPECIFICATIONS PUBLISHED.

1880.

3880** **Electric conductors.** (Amended.) Jensen. (Edison Electric Light Company's disclaimer.) 8d.

1887.

16623* **Dynamo-electric generators, etc.** (Amended.) Goolden and Atkinson. 8d.

1891.

2046. **Electrically-propelled vehicles.** Hutchinson. 8d.

NOTES.

Dewsbury is anxious to have the best system of central station lighting.

Blackpool Town Council have decided to extend their electric lighting.

Lille.—It is proposed to use gas engines coupled direct with dynamos for the central station at Lille.

Telephone Bill.—We understand that there are over 100 opponents to the National Telephone Bill.

Gloucester.—Why should not the new Gloucester municipal buildings be fitted with electric light?

Dresden.—A committee has been appointed to procure plans and estimates for a central lighting station.

Alternate-Current Motors.—The *Fremdenblatt* newspaper, of Vienna, is printed by alternate-current motors.

Sutton Coldfield.—The promoters of the Sutton Coldfield Electricity and Gas Bill have dropped their scheme.

Paddington Central Station is being proceeded with energetically, much of the machinery being placed in position.

Gibraltar. — The specification for the lighting of Gibraltar by electric light will not be settled definitely until after Easter.

Electricity in Gas Works.—The Compagnie Parisienne du Gaz has installed a complete electrical laboratory in their works.

Electro-Harmonic.—The concert of the Electro-Harmonic Society is a ladies' night to-night (Friday) at eight, at the St. James's Hall (Banquet-room).

The Electric Combination of the Thomson-Houston and Edison Companies in America is to take the name, we hear, of the General Electric Company of America.

Halifax.—The Technical Instruction Committee have resolved to obtain tenders for a new technical school. These ought to and probably will include electric light.

Birmingham.—Messrs. Fowler and Lancaster have been awarded the contract for lighting the Grand Theatre, Birmingham. Both arcs and incandescents will be used.

Scarborough.—A provisional order was obtained last session for Scarborough. Nothing more has yet been done, but it is expected that further steps will be taken shortly.

Burnley.—The Burnley Gas Committee have received the report of the electrical engineer on the supply of the electric light, and resolved to make application to borrow £25,000 for plant.

New Telephone Company Bill.—The second reading of this Bill, for the rejection of which motions had been put down by Mr. Kimber and Sir A. Rollit, has been postponed to the 8th inst.

Edison-Swan Company.—Major Flood Page has been elected a director of the Edison-Swan Company in the vacancy caused by the death of Mr. Leyland, being also elected deputy-chairman.

The St. Pancras Vestry have given notice of the withdrawal of their deposited Bill, under which powers were sought to borrow £360,000 for the electric lighting of the whole of the parish.

East London.—A new electric lighting company is in process of formation, with the object of supplying the electric light to offices and houses and public institutions in the eastern districts of London.

The Institution.—At the next meeting of the Institution, March 10, the discussion on alternate currents will be concluded, and a paper read by Prof. Hughes, F.R.S., on "Oil as an Insulator," illustrated by experiments.

Isle of Wight.—By a majority the Local Board of West Cowes has decided to consent to the application of the Isle of Wight Electric Lighting Company to the Boar' of Trade for powers to light West Cowes by electricity.

Universal Pliers.—Dr. O. May, of Frankfort, has designed a pair of electrical engineer's pliers, which fulfil four purposes—pointed pliers, wire-cutters, metal shears, and hole-puncher. It should be an extremely useful tool.

Roundhay Tramway.—The success of the Rounday electric tramway amongst the inhabitants of Leeds seems perfectly assured, and active steps are being taken to bring into shape the project for a further extension of the line.

Aston.—At the meeting of the Aston Local Board the proposal of the Baths Committee, that the offer of the Free Library Committee to pay £32 per annum for the supply of electric light to the Free Library be accepted, was adopted.

Arc Lamps for Shops.—Where a richly-dressed window is lighted with arc lamps it is sometimes very awkward to get at the lamp for trimming. In Berlin lamps in such places are not suspended, but sent into the window on runners.

Indian Telegraphs.—The telegraph has been extended from Bhamo to Nampoung post on the Chinese frontier. There is now a gap of only 65 miles between the terminus of the English wire and the Chinese telegraph station at Momein.

Coast Telegraphs.—The Clyde Steamship Owners' Association has forwarded to the House of Commons a petition praying for the establishment of a coast line of telegraph connecting all the coastguard stations and lighthouses of the Clyde.

Blackpool Tramway Bill.—The Blackpool Electric Tramway Company, through their agents, have deposited in the Private Bill Office of the House of Commons a petition praying to be heard by counsel against this Bill when it reaches the committee stage.

Physical Society.—At the Physical Society, Science Schools, South Kensington, to-day (Friday), at 5 p.m., Prof. S. P. Thompson will bring forward "Modes of Representing E.M.F.'s and Currents," and Prof. Perry will read a paper on "Choking Coils."

Examinerships.—The University of London, on April 27, will elect examiners (amongst others) in physical science; salaries, £210. The present examiners are Prof. G. F. Fitzgerald, F.R.S., and Prof. Oliver Lodge, F.R.S., who are offering themselves for re-election.

Walsall.—The Corporation of Walsall, as will be seen from their advertisement, are inviting tenders for supply and erection of a central electric light station. Particulars, with plan, can be obtained from Mr. John R. Cooper, town clerk. Tenders to be sent in by April 9th.

Mexborough (Yorks.) Local Board is considering the question of purchase of gas works. Gas is 3s. 6d. a 1,000, which is high for a Yorkshire town. The Board had better consider an electric lighting scheme. They will have to do this some day, and why not now?

Aberdeen Library.—The librarian has been instructed to enquire into the possibility of lighting the building by electricity, and to ascertain if the directors of the infirmary—which, it will be remembered, is already lighted—are in a position to supply current for such a purpose.

British Representation at Chicago.—A meeting of the London Chamber of Commerce will be held on Friday, March 11th, at 3.30, at the Mansion House, under the presidency of the Lord Mayor, in connection with the British representation at the Chicago Exhibition.

Proposed Pacific Cable.—A Reuter's telegram from Sydney states that the New South Wales Government is willing to subsidise the section of the Pacific telegraph cable between Queensland and New Caledonia on condition that Government messages shall be transmitted free.

Boiler Patents.—Models of Messrs. Zahikian and Michaux's patent arrangement for prevention of boiler incrustation, and consequent saving of fuel, are to be seen at 90, Victoria-street, Westminster. A small syndicate is being formed, with offices at 1, Quality-court, Chancery-lane.

Central Station Cranes.—The Gas Committee of the Manchester Corporation invite tenders for the supply of cranes to their electric light station, by March 10th. Applications, accompanied by a deposit of two guineas, to be made to Mr. Nickson, Gas Department, Town Hall, Manchester.

Bulgarian Telegraphs.—With a view of improving telegraphic communication between Adrianople, Philippopolis, and Sofia, the Bulgarian Government proposed to establish a telegraph line between Doblintza, Djoumaa, Eghri-Palanka, and Kustendil. It has been decided to undertake the works.

Municipal Engineers.—The Incorporated Association of Municipal and County Engineers will visit the West Brompton and the Kensington Court electric lighting stations on Saturday, March 12. A considerable number of the members will visit the Crystal Palace Exhibition on the previous evening.

Coventry.—At the meeting of the Coventry City Council on Tuesday, on the proposition of Mr. West it was decided that a deputation from the Council visit the Electrical Exhibition at the Crystal Palace, with the view of obtaining information as to the production and distribution of the electric light.

Lytham Pier.—Mr. J. Stevenson, chairman of the Lytham Pier Company, intends visiting the Crystal Palace Exhibition in a few days, with reference to electric lighting on the pier, the directors contemplating lighting the pier throughout by electricity, a building for the storage of the necessary appliances having already been put up.

Leeds.—The Leeds Town Council have authorised the expenditure of £500 by the Corporate Property Committee to provide a new installation of electric light for the free public library. Alderman Gibson thought it was better at once to remove the machinery to a separate building, as it caused vibration, even if the cost were more. It is proposed to add 133 lights.

Mansion House.—We are asked to notify that the private view of their electric light installation at the Mansion House announced by the Planet Electrical Engineering Company for Tuesday, March 1, has been postponed to Monday evening next, the 7th inst., between 6 and 10 p.m., to enable the Lord Mayor and Lady Mayoress to be present.

Battersea.—At the meeting of the Battersea Vestry last week, the Electric Lighting Committee recommended, with regard to the application by the Putney and Hammersmith Electric Light Company for a provisional order, that [illegible] as the company were prepared to supply electrical [illegible] Vestry should consider the advisability of lighting the public streets by electric light. The matter was adjourned for three months.

New Telephone Company.—A Pioneer Telephone Company has been formed, lists closing yesterday, to take over the Mutual Telephone Company of Manchester, and to provide the necessary capital for the New Telephone Company, Limited (whose Bill is now before Parliament), in the same way as the Pioneer Lighting Company did for the City of London Company.

City Lighting.—The City of London Electric Lighting Company has been making itself pretty evident to financiers lately, not in any occult way, but in the purely practical fashion of taking up the pavements of Old Broad-street to lay their pipes and conductors. Long lengths of streets are now laid, both here and as far as Fenchurch-street Station. The light will soon be at the disposal of the magnates of the City from Aldgate to St. Paul's.

Telephone to Ireland.—We are authoritatively informed that there is no foundation whatever for the report circulated in some quarters that a telephone cable is to be laid to Ireland. No such idea is contemplated. A new telegraph cable is to be laid, which perhaps may have given rise to the rumour of the establishment of a telephone line—an enterprise, however desirable, considered beyond practical range of accomplishment at present.

Omnibus Lighting.—The London General Omnibus Company has found the use of pocket electric lamps so useful to its ticket inspectors that the whole staff is now fitted. The lamps have been supplied by the Bristöl Electric Lamp Company, and the number of lamps amounts in all to 60; they are of 1 c.p. or 2 c.p., weight inclusive 2lb. each, secondary battery. The cost is 8d. per lamp per week. The omnibus company is to be congratulated upon their initiative.

Nottingham.—The Nottingham Town Council decided some time ago to establish a central electric lighting station. They have empowered a committee to draw up a specification of the works and plant required, with an estimate of the cost. The committee have recently visited the Crystal Palace with the idea of informing themselves upon recent progress in electrical practice, but will not arrive at any definite decision without the assistance of one or more experts.

Spanish Telegraphs.—Tenders are required on 10th March by the Direction Generale des Posts, 10, Calle de Carratas, Madrid, for 25,000 porcelain telegraph insulators (1f. 50c.), 3,000 ditto for telephone (80c.), 16,260 poles various sizes, 60 tons 4mm. wire (441f. per ton). Caution-money 5 per cent. Also, 12th March same address, 12,845 poles; 14th March, 20,000 insulators (1f. 50c.), 85 tons bronze wire, 3mm. (3,200f. per ton); and 26th March, 40,000 zinc cylinders.

Minehead.—Mr. G. Hayward has had the electric light introduced into his mineral-water factory and other parts of his premises. The installation consists of a 40-light compound-wound dynamo driven by a 3-h.p. Otto high-speed gas engine. The wiring of the premises and fixing all the various lamps, switches, fuses, and other fittings were entrusted to Messrs. King, Mendham, and Co., of Bristol, Mr. R. Clark and Mr. M. Capron assisting their electrician, Mr. A. Rouch.

Derby.—At the meeting of the Derby Town Council on Wednesday, the Mayor moved that the Electric Lighting Committee be authorised to take steps to obtain an extension of time for the laying of the electric mains in the compulsory area of the borough as defined by the electric lighting order, 1890. He stated that the time under the

present order would expire on August 4th, and he understood from Sir Frederick Bramwell that if an extension was granted it would not exceed three months. The motion was agreed to without discussion.

Gas Engines for Theatres.—The London County Council have adopted a series of rules and regulations with regard to the electric lighting of theatres and other places of entertainment. One is that gas engines employed in this connection are to be placed in rooms so adequately and continuously ventilated that no explosive mixture of gas can accumulate by any leakage from the engine in the event of any of the gas-cocks being left turned on. A hood, connected with a pipe carried into the external air, is to be fixed over the ignition-tube, when this is used.

Electric Traction Finance.—A meeting of the Society of Engineers will be held at the Town Hall, Westminster on, Monday next, March 7th, at 7.30 p.m., when a paper will be read on "Electrical Traction and its Financial Aspect," by Mr. Stephen Sellon. The following is a synopsis of the paper: Object of paper; accumulator system; overhead system; conduit system; National Telephone clauses; Roundhay electric tramway; working expenses in America; Blackpool electric tramway; Waller-Manville system; the commercial question; cost of construction for horse, cable, and electricity; comparison of working cost for each system. Visitors are admitted.

Band Music by Telephone.—An interesting and amusing instance of the efficacy of the London-Paris telephone occurred the other day which is worth recording. The Salvation Army band were marching from the Royal Exchange playing the "Marseillaise," when an idea struck the members present in the telephone-room. The windows and doors were thrown open and the attendant at the Paris end was asked if he could hear anything. The response (in French) was immediate, "Yes, I can hear a band playing the 'Marseillaise.'" That a band of music playing in the streets of London could be plainly distinguished in Paris is, we think, a sufficiently striking marvel of the nineteenth-century science.

Dynamo-Electric Machinery.—The new edition of Prof. Silvanus Thompson's work on the dynamo will be published in about a fortnight. Considerable alteration has been made, the whole has been practically rewritten and brought up to date, large additions have been made, and an appendix containing diagrams and working drawings greatly add to the usefulness and practicability of this most useful and practical of technical books. The size will reach 800 pages, and the price, we understand, will be slightly raised, making the net selling price equal to the present published price—viz., 16s. The appearance of the new edition has long been awaited with interest by students and engineers alike.

Incandescent Lamp Manufacture.—The Edison-Swan patents have only two years to run. Is it worth while to fight? Apparently not, for the letter issued by the Sunbeam Lamp Company, hitherto left in peace to make high candle-power lamps, says: "We much regret to have to inform you that owing to the action taken by the Edison and Swan Company, we shall be unable during the continuance of the Edison patent to meet any more of your valued orders for Sunbeam lamps. We have consented, rather than enter into a costly litigation with the Edison and Swan Company, and in view of the early expiry of both their patents, to suspend their manufacture." The Edison Company are warning not only makers but all users of lamps against using other than those of Edison-Swan manufacture.

Automatic Messenger Call-Box.—A very ingenious automatic machine has been established near the letter-box at Charing Cross railway station for the collection of letters to be forwarded by the Post Office express service. It is in electrical connection with the postal telegraph office opposite the station. By dropping a penny into the slot and pulling out the slide a brown-coloured envelope is delivered. This envelope contains another envelope and a card. The communication is intended to be written on the card, which is then enclosed in the white envelope, and this, with the fees for delivery, which have been fixed at 3d. per mile, is re-enclosed in the outer envelope and deposited in the box behind the flap which bears the printed instructions. The act of withdrawing the slide sends the call signal to the telegraph office, and a messenger is at once despatched to collect the special letters.

Bulgarian Telegraphs.—Tenders are notified by the French Minister of Posts and Telegraphs until March 8, at the Commission Permanente de Sofia, under seal, for 37,000 kilogrammes of telegraph wire of 4mm., 500 kilogrammes of 2mm. wire, 11,000 insulators, and 11,000 brackets. These are to be furnished as follows: at Lom Palanka, 15,000 kilogrammes of 4mm. wire, 3,500 brackets and insulators; at Rustchuk, 1,200 kilogrammes of 4mm. wire, 4,000 brackets and insulators; at Sofia, 10,000 kilogrammes of 4mm. wire, 500 kilogrammes of 2mm. wire, 3,500 insulators and brackets. Separate tenders can be sent if desired. The total value is limited for the 4mm. wire to 18,500f., 2mm. wire 300f., brackets 7,000f., and insulators 10,000f.—a total of 1,790f. Deposit-money is required. Further details at the Sofia Commission Office, or of the Bureaux des Renseignements Commerciaux, 80, rue de Varenne.

Salford.—At the monthly meeting of the Salford Borough Council on Wednesday, Mr. Phillips moved a resolution of the General Gas Committee that it was expedient that the Corporation exercise within the borough the powers conferred upon them by the provisional order for electric lighting. The committee had in view in adopting a scheme to agree only to have a comparatively small installation, which would preserve to the borough the right of electric lighting, and as occasion arose afterwards extensions might be made. The Board of Trade had sanctioned a small area, and the lighting would be confined at present within that area. An amendment was moved that the exercise of the powers should be postponed, there being no need to fear terrible results from the establishment of a private company. The amendment was lost by a large majority. Mr. Phillips explained that the cost of the first installation would be £15,000 to £20,000.

Liverpool.—At the meeting of the Liverpool City Council on Wednesday, Mr. Hornby moved the adoption of the recommendation of the Watch Committee that the Board of Trade be informed that the Corporation were willing to withdraw their opposition to the Liverpool electric lighting provisional order, 1892, and to give their consent to it being granted, provided it was amended in accordance with the terms approved of by the committee. Mr. Hornby explained that this was a fair compromise, the Corporation securing power to purchase the undertaking after the lapse of a certain period. At particular intervals the Board of Trade might be approached, and might alter the mode and amount of payment. Alderman Dr. Cross ascertained that provision had been made for regulating the price of the electric light to the public, according to the increase of dividend. When the dividend was over 7 per cent. the surplus was to go towards the reduction of the price. The recommendation was confirmed.

Tesla Apparatus.—Our readers will be interested to learn that a Tesla experimental apparatus is being con-

structed for lecture purposes at the Finsbury Technical College. The students will be very much on the *qui vive* the first time Dr. Thompson ventures to take the million-volt shock into his body. Some one must evidently follow suit to Mr. Tesla, but we have heard the opinion expressed by several engineers that they would hardly like to build and test such an apparatus with a trust in its harmlessness merely from abstract or mathematical reasoning without trying it, say, on a calf first. Mr. Tesla has a splendidly-equipped laboratory in New York, and the experiments he showed at the Royal Institution are by no means all he had to produce, given more accurately determined conditions. With the experimental skill of Finsbury also turned on to this new branch of electricity—the "vibratory current" system—we may soon see electric lamps without wires—primitive, no doubt, but yet alight—amongst the regular course of lecture demonstrations at technical colleges.

Manchester Central Railway Station. — The Central Railway Station at Manchester has been brilliantly lighted by 40 arc lights of 2,000 c.p., distributed over the platform and approach. The offices, refreshment-room, and bookstalls are lighted with incandescent lamps of 16 c.p., handsome electroliers being supplied in the public rooms. The generating plant is placed under the arches beneath the viaduct, the cable being led along the line to the station. Two powerful compound engines have been supplied by Messrs. Mather and Platt, driving Edison-Hopkinson dynamos. The boilers are by Messrs. Galloway, and the whole plant is in duplicate, with special arrangements for interchange of service. The general arrangement of the lighting has been arranged by Mr. W. G. Scott, the chief engineer of the Cheshire Lines Committee, who are so well pleased with the results that they have commissioned Messrs. Mather and Platt to make the necessary increase in the plant for lighting the whole of the goods department. Active preparations are now being made for the erection of 76 1,000-c.p., 10 2,000-c.p. arc lamps and 65 16-c.p. incandescent lamps. The whole of the gas will then be replaced by the electric light, the installation forming one of the most important which has yet been supplied to any railway company in the kingdom.

Stone-Carving by Electricity.—Electricity has now been put to many uses, the very latest being the working of a machine which it is thought will revolutionise the art of stone carving. The inventor is a Colorado man, Mr. W. P. Carstarphen, and the invention is described in the Denver *Sun*, and consists of a small reciprocating electric drill. The tool is provided with a reciprocating plunger, located and moving within the two solenoids of insulated copper wire, through which a direct current of electricity is alternately passed. The current for operating the tool can be supplied from any suitable electrical source, such as an ordinary primary battery or a dynamo, and is simultaneously switched from one coil or set of coils to the other by the use of an automatic switch placed between the two coils and controlled by the reciprocation of the plunger. The current is led to one end of the tool through a revolving swivel, and the rapidity of the strokes made by the plunger is regulated by a button on the side of the tool. In the model, which is a 3lb. tool, the stroke can be made to vary from ⅛in. to 1in., with a motion varying from 50 to 300 strokes per minute. To run a tool of this size from four to six volts only are required. Portable storage batteries, 12in. by 6in. by 6in., have been made, which are encased in a neat box, and intended for operating the tool on scaffolds and elsewhere away from the shop. These have energy *sufficient for a day's* work, and can be recharged overnight at an expense not to exceed one shilling. With this tool the carver or sculptor instead of dividing a portion of his attention to striking his chisel, can devote his entire attention to the lines which he is following, thus producing more accurate and rapid work. It is estimated that the machine will produce work in one-fourth the time of hand work, and therefore a material reduction in the cost will be secured. Although 6lb. is the heaviest tool constructed thus far, the principle of the machine can, it is said, be carried into those of endless variety and size, and suited to all purposes, from the most delicate sculpture work to the heaviest of granite drilling and mine work.

Electric and Cable Railway Schemes.—In the House of Commons on Tuesday Mr. Whitmore moved: "That a Joint Committee of Lords and Commons be appointed to consider the best method of dealing with the electric and cable railway schemes proposed to be sanctioned within the limits of the metropolis by Bills introduced, or to be introduced, in the present session, and to report their opinion as to whether underground railways worked by electricity or cable traction are calculated to afford sufficient accommodation for the present and probable future traffic; as to whether any, and which, of the schemes propose satisfactory lines of route; as to the terms and conditions under which the subsoil should be appropriated; whether any, and, if any, what, schemes should be proceeded with during the present session; that a message be sent to the Lords to communicate this resolution, and desire their concurrence." He urged, in support of the motion, that the proposal was supported by the Corporation and the County Council of London. He justified his proposal for the creation of an unusual tribunal by pointing out that electric and cable schemes were very numerous and very important, and that it would be well for the future comfort and convenience of London if, at the outset, an authoritative enquiry by such a joint committee as he suggested took place instead of referring Bills to different committees. Mr. T. H. Bolton, in rising to second the resolution, said that he believed the reference would cover all the important questions which might arise in connection with these railways. Mr. Kimber moved, as an amendment, to add the words, "Provided that such committee, before reporting that any schemes for which Bills have been deposited should not be proceeded with, shall have first heard the parties promoting such Bills, and, if desired by them, receive evidence thereon." Mr. Courtney thought that the present would not be a convenient time to move the amendment, and suggested that it should be withdrawn. The amendment was then, by leave, withdrawn. Mr. Isaacs, while entirely concurring in the resolution, hoped that the committee would lay down some condition by which promoters of any of these schemes would not be allowed to interfere with the metropolitan lines. The resolution was agreed to.

Croydon Tramways.—At the fourth half-yearly general meeting of the Croydon Tramways Company held on February 23rd at The Guildhall Tavern, Gresham-street, Mr. W. J. Carruthers-Wain (the chairman), with reference to the question of traction said: "We have taken a step in advance, I think, which I hope will redound to our credit and to our spirit of enterprise, on the principle of heads we win and tails we don't lose. In other words, we have made arrangements with the Electric Tramcar Syndicate, who have placed cars on our lines, that we shall pay them so much a mile, that amount which we are paying them per mile not being more than it costs us for horse traction at the present time, and the surplus being our property. I have had some figures prepared, showing the miles run by the electric cars since they were first put

on. Of course, they have been running under difficulties of weather and of incomplete installation, and other things which a technical mind would easily understand; but those difficulties are being rapidly remedied, and I believe the cars will be run very successfully. If they are not, it will not be the fault of the inventor, Mr. Jarman. The number of miles run by the electric cars in the month of January was 662, and they earned £39, which come out at the rate of 1s. 2½d. per mile run. That, in such a month as we had in January, is marvellous. Something is due no doubt to the novelty of the traffic, but I go a little further than that, for I believe that once you attract the public by a novelty, you attract them afterwards. 1s. 2½d. is a return which is not excelled by any other company, not even the great companies. It is equalled by one, but it is not excelled by any. That is an instance of the popularity of the electric cars and of their success. There may be a few mechanical alterations required, but so long as the financial part of the burden does not fall upon us, I think we should do all we can to help the syndicate to make the experiment successful from their point of view. It has been suggested that we should buy the cars and put up an installation. Nothing would give me greater pleasure, if we had the money; but as we have not, and while people are ready to come forward and put cars on our line, we can only say that we will help them to the best of our ability. We have no money to re-equip our line either with these cars or any other cars. If this experiment is a success, I have no doubt the Electric Tramcar Syndicate will be only too glad to put on more cars, for their own benefit."

Manganin.—Prof. Ayrton in his presidential address alluded to the lack of knowledge of many electrical engineers to the new German alloy "manganin," which constitutes a most useful material for the construction of electrical resistances. We have received the following particulars with reference to this alloy from Messrs. Abler, Haas, and Angerstein, of 18, Kommandanten-strasse, Berlin, and 23, Great St. Helens, London, the sole agents in the United Kingdom and abroad: Manganin is an alloy of manganese, copper, and nickel, especially suitable for electrical purposes. It is recommended by Dr. K. Feussner and Dr. St. Lindeck of the Government Physico-technical Laboratory in Charlottenburg (Berlin). Manganin has, according to the researches carried out in the above-mentioned laboratory, this most important quality, that it undergoes an almost inappreciable change of resistance with the variation of temperature. (See Dr. K. Feussner and Dr. St. Lindeck, *Zeitschrift für Instrumentenkunde*, 1889, p. 233; *Zeitschrift für Instrumentenkunde*, 1890, pp. 10 and 427; *Elektrotechnische Zeitschrift*, 1890, p. 243). In the range between 0deg. C. and 15deg. C. the resistance slightly increases at a mean rate of 0·002 to 0·003 per cent. From 15deg. C. to 30deg. C. (which is the common range of temperature in electrical measurements) the change of resistance is imperceptible even to the most delicate observations, the actual change being only a few millionth parts per degree. At higher temperatures the resistance slightly diminishes. This is the first authentic record of a metal diminishing in resistance with rise of temperature. The specific resistance of manganin is 42 microhm per centimetre cube, which is much higher than the resistance of other German-silver alloys. The specific resistance of manganin permits the use of much smaller resistance-boxes, when the coils are made of this material. On the other hand, when it is employed for current-regulating resistances stronger currents can be used with the same amount of material. In consequence of these qualities manganin is a most important material, not only for resistance-boxes, for which it is highly recommended, but also for voltmeters, and in general for all kinds of electrical apparatus in which constancy of resistance at different temperatures is required. The use of manganin gives, therefore, much more trustworthy results than any resistance material hitherto known. Manganin being very soft and pliable, tubes without seams can be drawn for resistance purposes. These tubes are supplied up to two metres in length and in various diameters. Samples, testimonials, and further information may be obtained on application at the London office, 23, Great St. Helens, E.C. It can be obtained in bare or in silk-covered wire, and in plates from 0·1 mm. to 4 mm. thick.

Cambridge. — At the quarterly meeting of the Cambridge Town Council held recently the Electric Lighting Committee reported: "That the Town Council has received an official communication from the Local Government Board, in answer to the application of the Corporation for permission to borrow the sum of £35,000 for the purpose of electric lighting, giving the sanction of the Board to the borrowing by the Corporation of £25,840 for the above purpose. This sum is, in the opinion of the committee, not sufficient to enable the Council to carry out the scheme proposed by Prof. Garnett, so far as regards any part of the town outside of the compulsory area described in the provisional order. Messrs. Parsons and Co. have made a proposal to the committee to form a company for taking over the powers and duties of the Corporation under the provisional order. The committee recommend that they be authorised to negotiate with Messrs. Parsons and Co. on the basis of their proposal, and that, failing a satisfactory arrangement with them, the committee be at liberty to negotiate with some other firm or company for the taking over of the corporate powers." Alderman Whitmore, in proposing the adoption of the report, said it would have been better if the Local Government Board had given them sufficient money to go on with the entire work. They had only granted £25,840—merely the sum required to supply the prescribed area, and not sufficient to carry out Prof. Garnett's scheme. He thought they ought to have sufficient money to extend the lighting to the whole of the town. Mr. Vintner opposed any grant from the rates to light any portion of the town; but he thought the advantage of the light should be within the reach of every inhabitant of the borough. He hoped that it would be distinctly understood that any negotiations commenced would be upon the basis of property reverting to the Corporation upon reasonable terms and within a reasonable period. He thought the application had not been properly submitted, as the loan of £25,840 did not admit of one shilling for an alteration of plant or extension of mains. Mr. Morley said the report was not worded according to what the committee had decided. Their idea was to ask the company for their terms, and then bring forward two reports—one giving the cost for the Council to do the work itself, and the other the terms of the company. He suggested the mover allow the following words to be added: "And bring before the Council two schemes—first, for the Corporation lighting the prescribed area itself; and, second, the offer of any company." Mr. Flack proposed, as an amendment, that the report should be referred back to the committee. Mr. Huddleston seconded, remarking that he trusted the report would go back with an understanding that if the company took the risk it should have the profits also. It was not to be supposed that any company would accept a contract for seven years also. After further discussion, in which it was maintained that there was no reason for the report being referred back, the amendment was defeated and the report adopted.

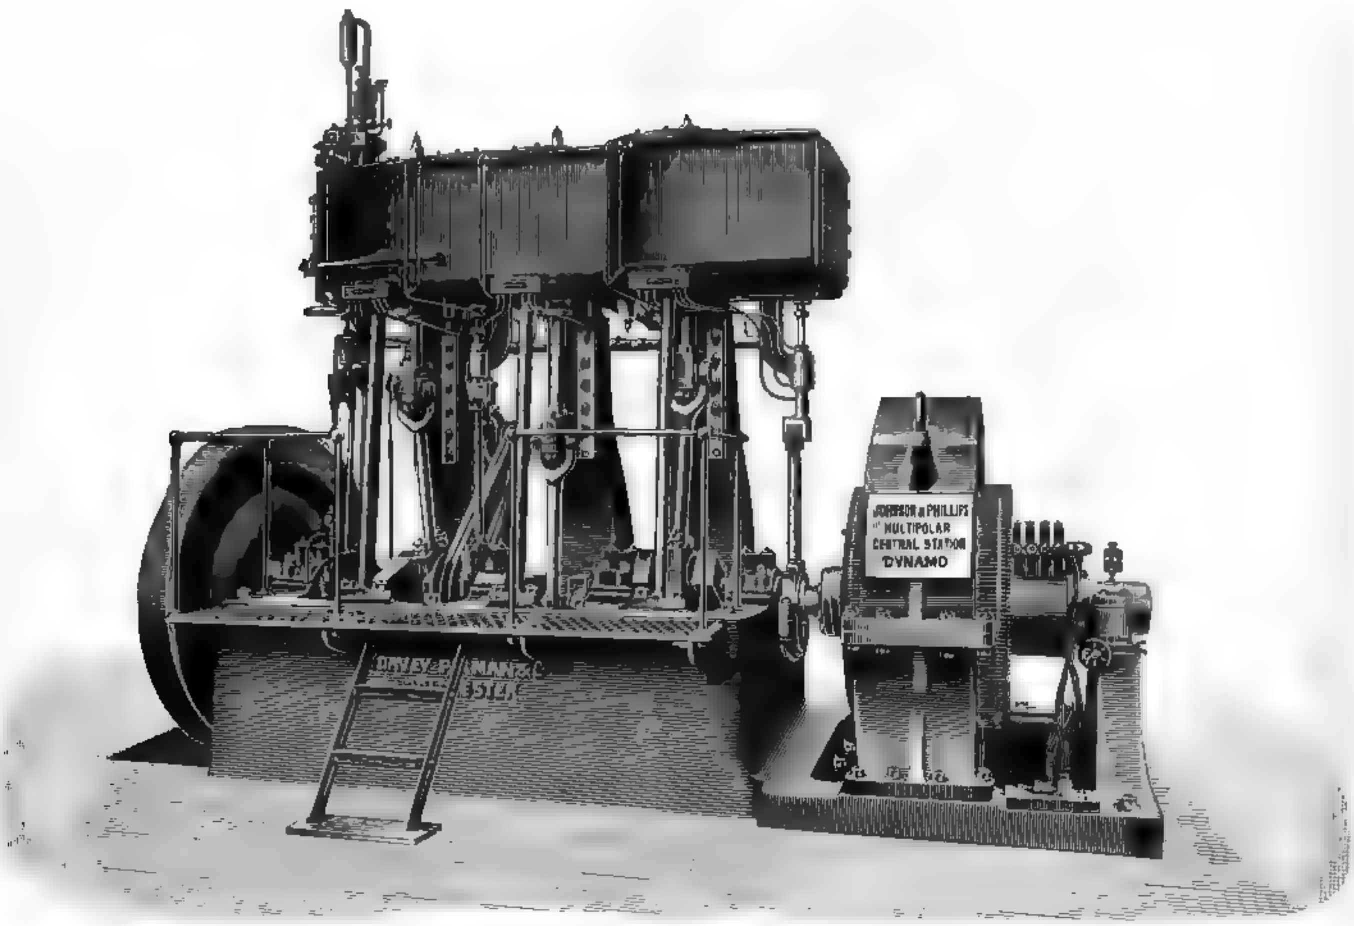
THE CRYSTAL PALACE EXHIBITION.

Although the Exhibition may now be looked upon as practically complete, a correspondent points out that even after this lapse of time from the opening the exhibitors have not placed all the exhibits in position which they necessarily led the editor of the catalogue to believe would be shown. The compiler of a catalogue is perforce compelled to take his lists of exhibits from the exhibitors, and it is the duty of the latter to install as quickly as possible the apparatus named. As we pointed out last week, the Crystal Palace authorities notify deputations, but there are visitors, really deputations, whose visit cannot be foreshadowed, yet these visits will lead to business. Take, for example, the Lytham Pier Company—a company which is now erecting a pavilion at the head of the pier. The chairman of the company is coming to London within the next few days to enquire into the matter of lighting the pavilion by electricity. Such orders are not large compared with central station work, but they are worth having, even if only from the view that "business" leads to "business."

From the exhibitor's point of view, the most important visitors of this next week will be the members of the Incorporated Association of Municipal and County Engineers, who are to be expected on Friday, March 11th. According to present arrangements, the members will visit the Palace on Friday evening, and on Saturday, among other visits, will see the West Brompton House-to-House station and the Kensington Court station.

In our last issue we described the motor-generator in use by the District Company for much of the Palace lighting, a slightly modified form of which is to be seen at the Electric Construction Company's stand in the Machine Department. A little further down the Machine Room is the conspicuous exhibit of **Davy, Paxman, and Co.** and **Johnson and Phillips**, the former showing, among other things, a three-cylinder engine coupled direct to a Kapp dynamo, built by Messrs. Johnson and Phillips.

The illustrations represent the large steam dynamo, as we say, jointly exhibited at the Crystal Palace by Messrs. Johnson and Phillips and Messrs. Davey, Paxman, and Co. The machine has eight field poles projecting radially inwards from a massive cast-iron yoke ring. The magnet cores, which are cylindrical, are 14½in. diameter, and the rectangular pole-pieces are also of cast iron. To facilitate the insertion of the armature the yoke is made in halves with horizontal joints; the top half can be removed by the lifting rings. The armature core is 48in. diameter by 18in. long, and is built up of segmental plates threaded on steel bolts and secured between strong cast-iron cheeks. The power is transmitted to the armature conductors by 64 metal driving horns, insulated with fibre and mica, the force transmitted by each driving horn being about 50lb. There are 362 bars on the armature, and the ends are connected by segmental plates insulated from each other and mounted in cast-iron carriages, which latter are screwed to the end cheeks above mentioned. This method of end connections has the advantage of leaving the ends of the armature perfectly open, which admits of excellent ventilation inside and of avoiding the crossing of conductors over the ends, which in the old-fashioned way of drum winding is so frequently a source of trouble. The difference of potential between adjacent plates is only 10 volts.



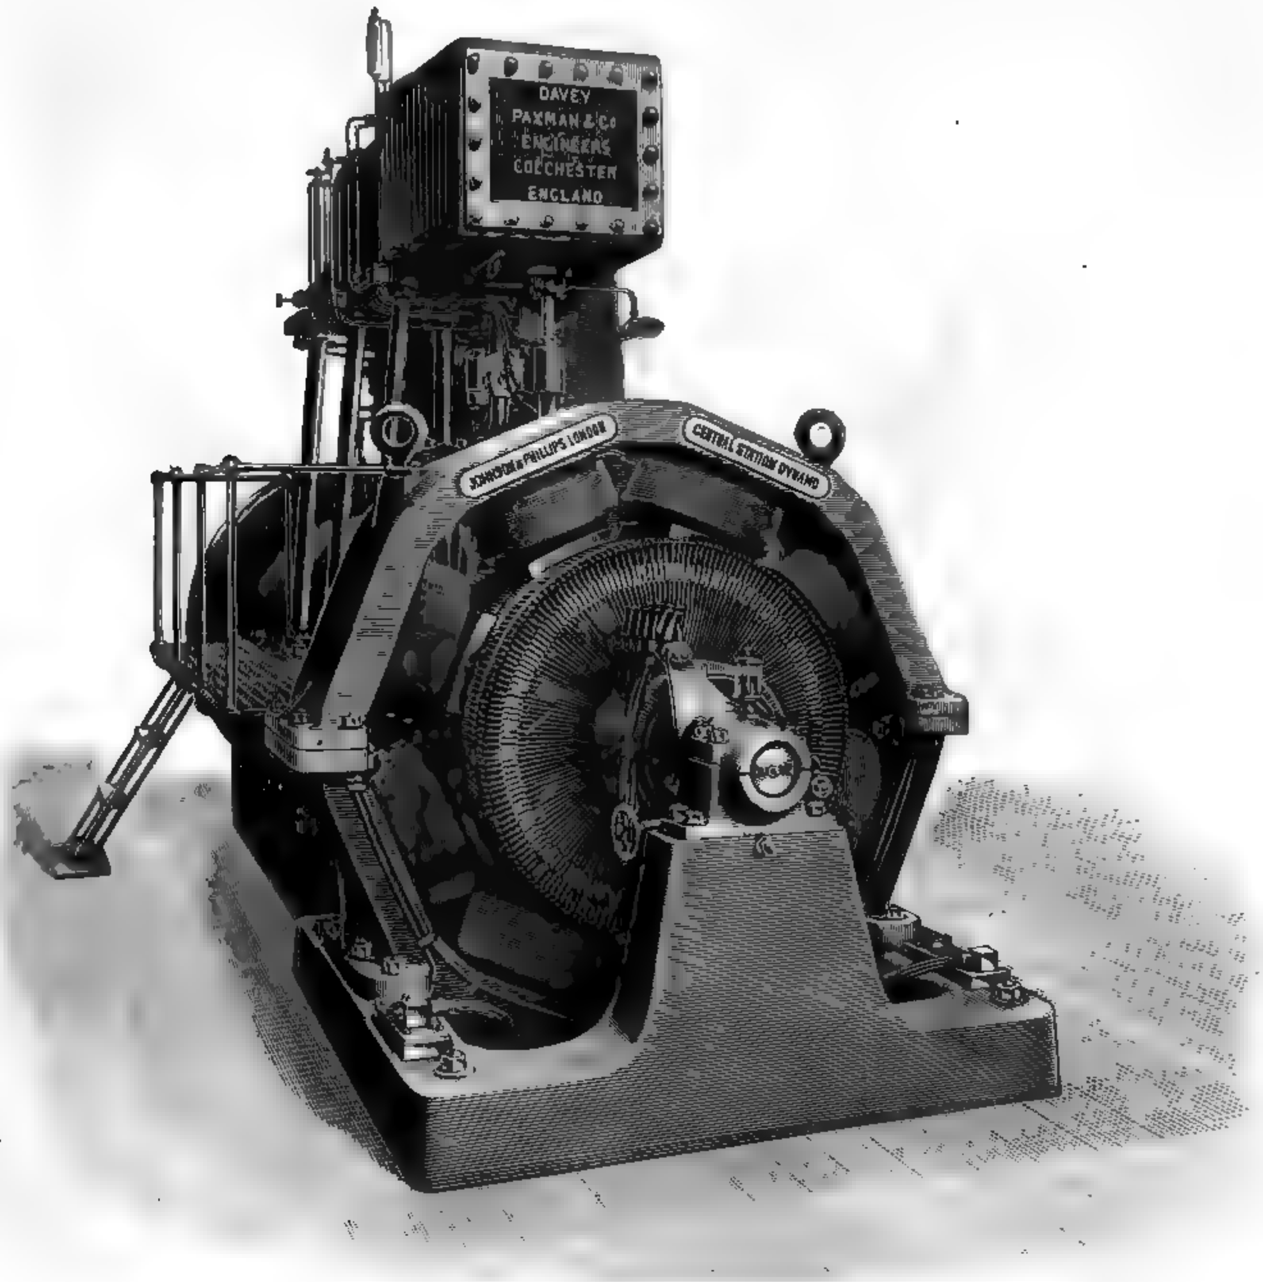
Paxman Engine Coupled to Kapp Dynamo.

The commutator contains 181 sections, and is 21in. in diameter and 12in. long. The current is taken off by two sets of brushes placed 135deg. apart, four brushes in each set. The machine is designed for an output of 550 amperes at a voltage which can be varied at will, from 200 to 260 volts. For charging batteries when a smaller current is required towards the end of the charge, the voltage may be forced up to 300 volts. The speed of the machine under all working conditions is intended to be 130 revolutions per minute, but as at the Crystal Palace a voltage of 205 volts only is required, the engine governor has been adjusted for a speed of 115 revolutions per minute. The exciting power of the field magnets can be varied by means of a rheostat so as to adjust the voltage within the limits above mentioned. The brushes are adjustable by worm gearing. The current from the machine is used for lighting the Picture Gallery by incan-

descent lamps (which have been fitted up by the Gulcher Company), also for some Gulcher arc lamps, and for a number of Brockie-Pell lamps, as well as for driving all the machinery on Messrs. Johnson and Phillips's stand. For the latter purpose the current is passed through a pair of small balancing dynamos, which split up the voltage into 70 and 130 volts, so as to make the current suitable for charging cells and work the ordinary type of machines exhibited on the stand.

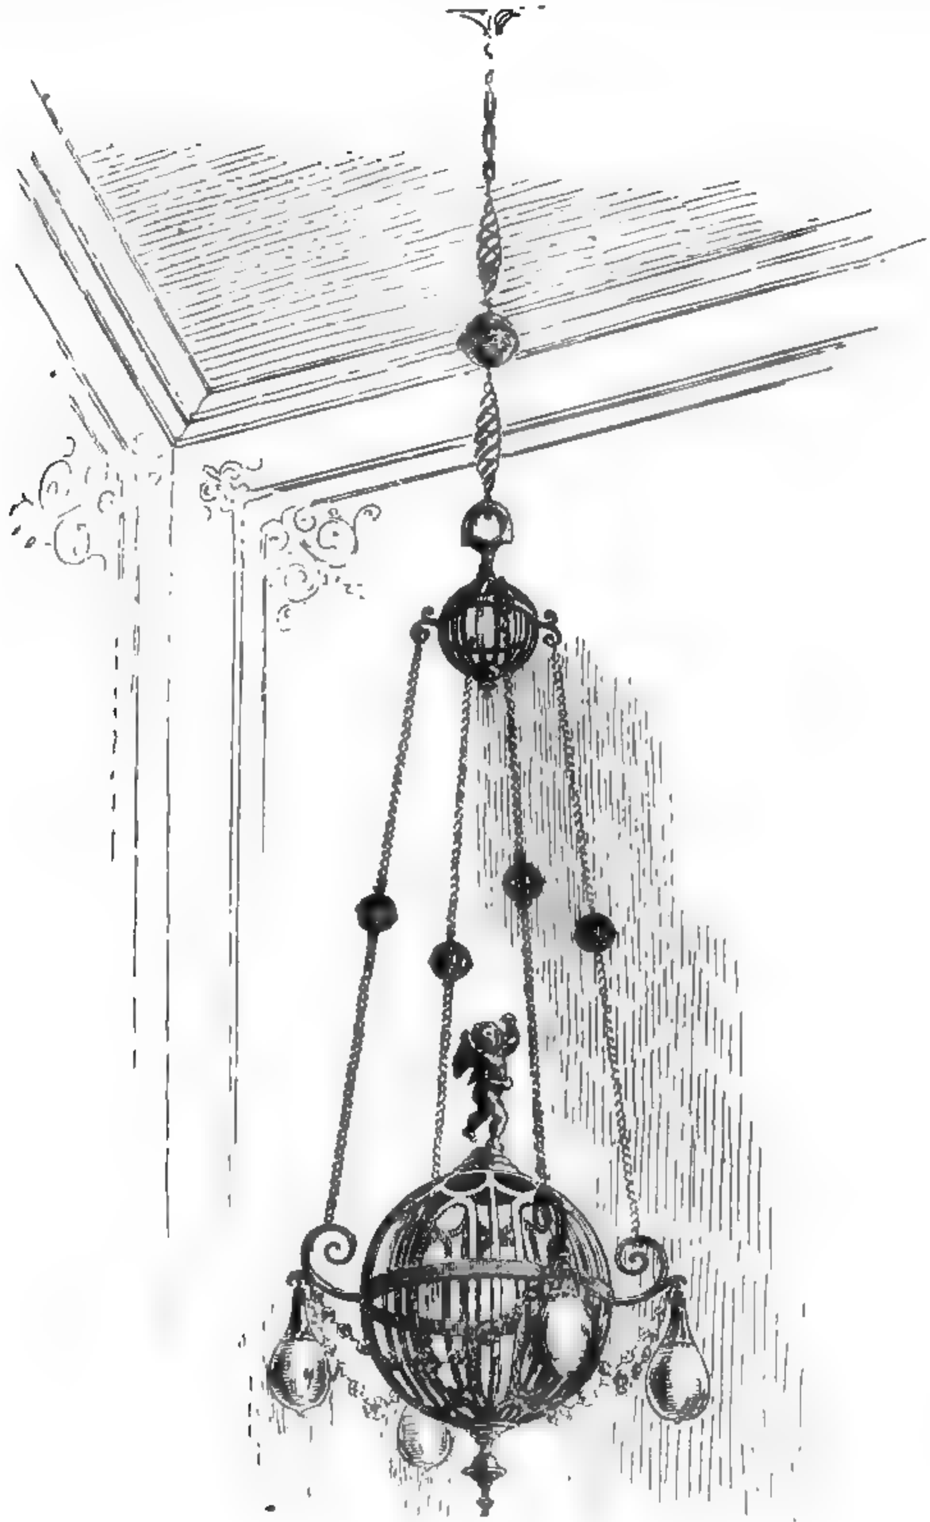
The engine is triple expansion, having cylinders 12in., 18¾in., and 30in. diameter respectively, with a uniform stroke of 18in. It is built for an indicated horse-power of 350, at 140 revolutions, or 320 i.h.p. at 130 revolutions and 160lb. steam pressure. The floor space, including platform, is 10ft. 6in. by 6ft. 9in., and from the floor line to top of cylinder covers is 11ft., the extreme height to top of sight-feed lubricators being 3ft. 2in. more. The platform is 2ft. 8in. above floor level. The steam is supplied from Paxman's patent water tube boiler at 130lb. pressure, and for the purpose of starting the engine in any position steam can be admitted direct into the intermediate steam-chest. The crankshaft is of mild steel, with slotted cranks 120deg. apart, and runs in four long bearings. The governor is of Paxman's improved design, extremely sensitive, keeping the engine under absolute control. When the governor lifts it pulls over a link, bringing the short-throw eccentric into action with expansion valve spindle, and cuts off steam earlier, keeping the speed constant. The three main eccentric rods are of best forged iron, finished bright, with adjustable brushes. The automatic gear is of steel, with forked joints, fitted with steel pins. The piston-rods, cross-heads, slippers, and valve spindles are of forged steel, the latter being swelled to work in guides. The connecting-rods are of best forged iron; the flywheel is 6ft. diameter.

Among the numerous displays of artistic electric light fittings at the Crystal Palace Exhibition, we think the palm for general elegance, beauty, and fitness of designs for the electric light must be given to the stand of **Messrs. Faraday and Son**. Other displays there are of great beauty, especially where cut glass is extensively called into play, as is the case with one well-known stand, and many exhibitors show a great variety of elaborate and fanciful fittings, which are more or less suitable for the artistic decoration of houses with electric light. But if we examine quietly the many beautiful fittings at Messrs. Faraday's stand, the individuality and appropriateness of the designs there shown are very striking. And when it is mentioned that the electric fittings at the exhibit which everyo acknowledges to be one of the features of the Exhibi that of Messrs. H. and J. Cooper—have been out by Messrs. Faraday and Son, it will wrought standards firm take in the present Exhibition, as ich are so designed as a very high place in commending itching upon the wall for light to the public.



Kapp Dynamo Coupled to Paxman Engine.

The stand itself is very characteristically fitted up, with walls hung with serge of a soft green tone, the columns, arches, and recesses being draped with velvet of warm harmonious tints. The stall is roofed, with diaper ceiling, and outside the front is canopied by a silken awning supported with Syrian spikes. Indian matting and Persian rugs cover the floors. On two sides small recessed Georgian windows are prettily inserted, shaded with ferns in pots, and through these windows delightful glimpses of the long galleries, or the tropical palms and ferns that encom-
ththem, can be obtained by the visitor.
Departi is laid on for over 100 lamps, which are mounted
the conspif.fittings. In the centre of the wall is a fine
and **Johnson** al Faraday, lighted by a suitable picture
other things, a themiling down on the handsome exhibit
Kapp dynamo, built bythe lights that glisten from all
*The illustrations repre*alleries. In the centre o! the

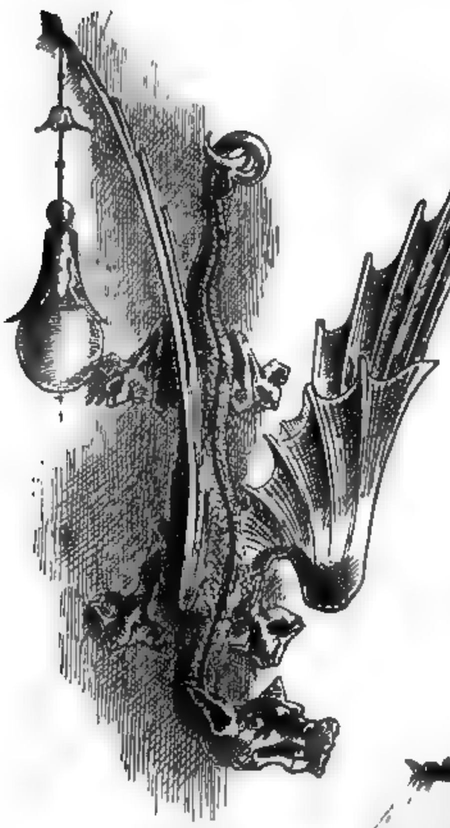


Drawing-room Pendant by Faraday and Son.

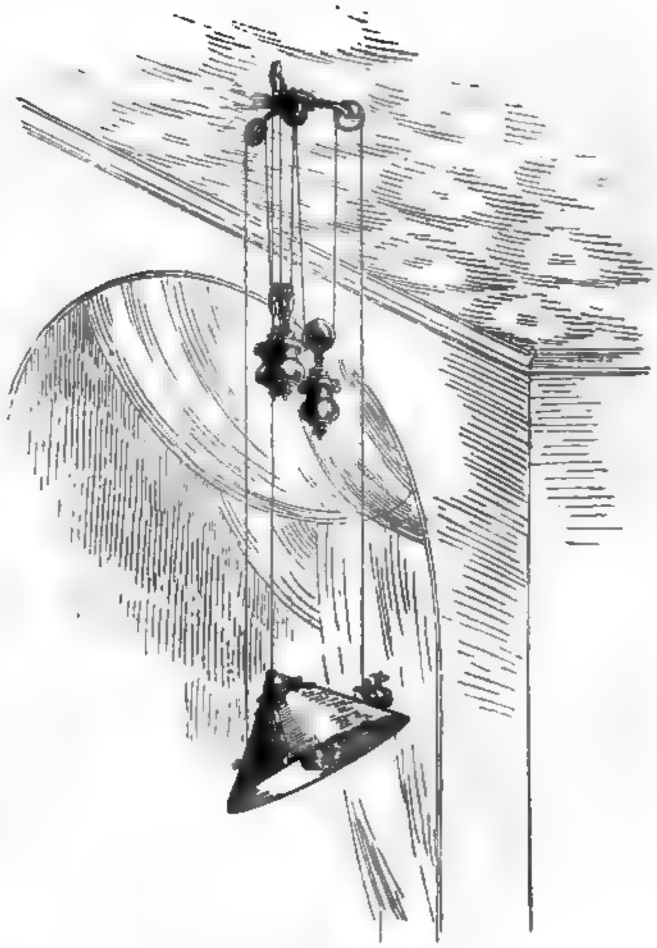
stand is a large electrolier in silver for 15 lights, suitable for a large drawing-room, the five triple sprays being supported by caryatides. From the centre also hangs a fine ballroom chandelier in chased metal, with crystal hangings. A speciality in this exhibit is that of fittings having tasseled bead shades hung around the incandescent lamps, which give a pleasing subdued glow and suitably replace the glass, silk, or paper shades. A five-light chandelier of delicate design is thus fitted, and has a handsome appearance. Other smaller pendant lamps are also fitted with these tasseled golden beads, and others with silver tassels of the same kind.

Persons of taste, with a desire for originality, will notice with pleasure the swinging pendant of a flying dragon carrying three lamps, while the reproduction of Pompeian oil-lamps, with their flame represented by a torch-shaped frosted incandescent lamp, has a very pleasing effect.

Another to be noticed is a light and graceful globe of open metal, swinging by chains and surmounted by a figure of Cupid with his bow. Little cupids in fact, are several times invoked to add the antique mythical flavour to the soft light of the electric lamp, as for corners of boudoirs or in the canopies of beds.



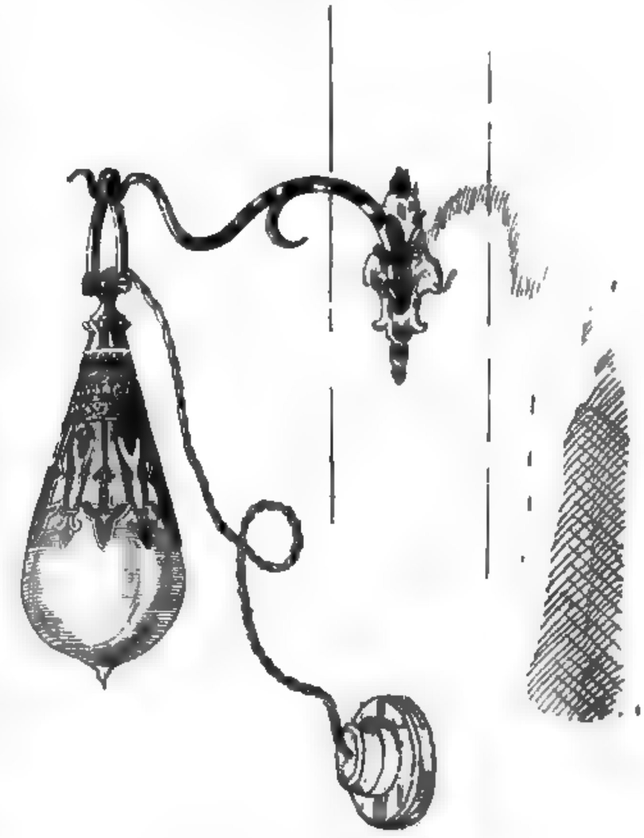
Dragon Bracket.



Sir D. Salomon's "Perfect" Pendant.

Faraday's Filagree Pendant.

Table Standard.



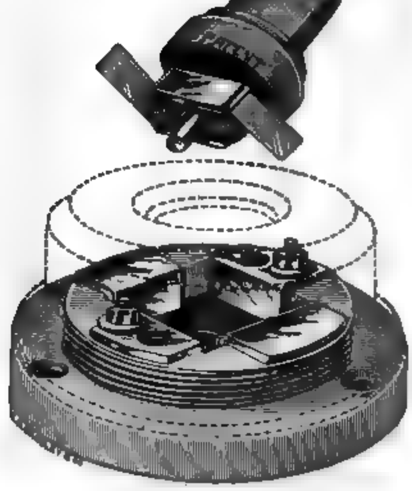
Faraday' Movable Side Lamp

The flying figure of Mercury, with wand and winged sandals, carries a lamp at extended arm length, while a Bacchus also forms a tasteful stand for the same purpose. There are quite a variety of chased and wrought standards for portable table lamps, some of which are so designed as to be equally suitable also for hitching upon the wall for

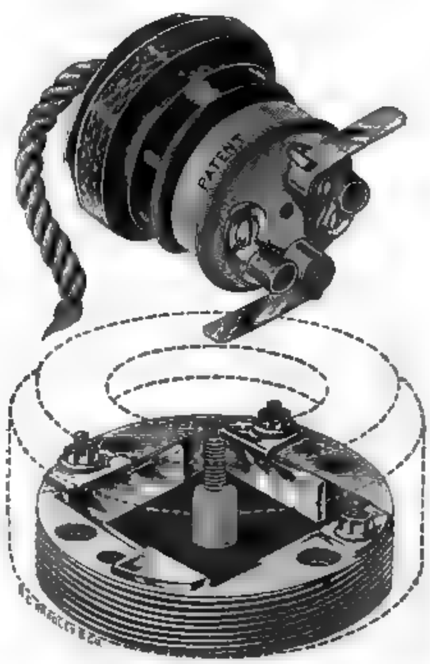
use as brackets or over-bed lamps, the shades being fitted on trunnions for reversing. A portable table lamp in nickelled silver, with sliding arm with a revolving action for a shaded lamp, is also to be noticed. There are several counterweight pendants specially designed for dressing-tables and for reading-desks.

A noticeable counterweight pendant, of peculiar design, is that termed the "Perfect," designed by Sir David Salomons, and of which Messrs. Faraday are the sole makers. A reflector of suitable design is suspended by three cords, each having a counterweight. The pendant has then the peculiar advantage that it may be canted so as to illuminate or cast into shade any portion of the room at will. It is equally adapted to large or small lights, and to cheap or costly fittings. That shown is suitable for a library or writing-desk, and is prettily finished with small dolphins. Several of Messrs. Faraday's fittings are furnished with quaint designs of winged dragons or dolphins in bronze, also goats, ram's heads, swan's necks, and so forth, in wrought, gilded, or oxidised metal. These are worked into the wall fittings combined with the very elegant lampholder long introduced by Faraday's, now made sufficiently large to contain the bayonet-jointed lampholder as generally used. These socket holders can be of the kind now rendered fashionable by this firm. Sanctuary lamps are also seen, swung by chains, and moulded on old forms taken from Spanish and Florentine originals of the sixteenth century, and these in pierced and embossed hand-worked metal are peculiarly effective in toning the glare of the electric light for quiet corners.

In the "Princess Christian" rooms of Messrs. Cooper's exhibit, Messrs. Faraday have a variety of fittings in place. There we find wrought-iron lobby lanterns, winged dragons carrying lamps, figures of Mercury and Iris holding lamps, besides dolphins and cupids. In the Oriental room is a reproduction of a Cairene brazier, Arabian painted glass pendant vases, besides the centre pendant. The dining-table is fitted with a handsome centre pendant, the bedroom with silver Louis XVI. dressing-table bracket, Greek tripod writing-table standard, pierced silver pendant, and cupid lamps at the bed head. A very comfortable easy reading-chair is fitted with movable electric bracket, as illustrated in Mrs. J. E. H. Gordon's delightful book on electric light decoration. Japanese and Moresque fittings are interspersed in corners, and the whole set of rooms diffused with a soft and lovely glow. No one who visits the Exhibition should leave without a good look at Messrs. Faraday and Son's exhibits.



A. P. Lundberg's "Unique" Switch.



The "Unique" Combination (Switch Wall Socket).

S. Smith and Son's Non-Magnetic Watch.

obtained alone in different material, hammered brass or gilded metal, in the graceful forms of the lily, the tulip, or the lotus, making the simple frosted incandescent bulb into an harmonious thing of beauty.

Besides these fittings proper Messrs. Faraday show a variety of shade-holders, or supports, in cast or pierced metal, also floral in treatment. Screens, shades, and light diffusers of various patterns, and mantles of sober tints soften the glare of the naked electric light. Some lovely samples of real Venetian glassware are also shown. One method now very usual in high-class houses is well illustrated in this exhibit. This is to use wall brackets or candlesticks with the globes screened by shells or tapestry shades from the eyes. These are made in a large number of different shapes and tints, and produce a very beautiful effect in a handsomely-decorated room.

Of switches and safety fuses Messrs. Faraday show some of their own design of fireproof material, but avoiding the usual mechanical appearance given by many makers to these necessary adjuncts. Being comparatively diminutive and boxed in ivory or in silver cases, they are suitable for any boudoir or drawing-room.

Amongst other fittings of fanciful and delicate design we see swing baskets in light scroll metal for flowers, with radiating arms of simple design, from which are dropped tiny pendant lamps. Single pendants for lobbies and bays are shown, some taking the form of old Venetian cressets of the fifteenth century, others with delicate filagree work

Amongst novelties in switches a noticeable type is shown by **Mr. A. P. Lundberg**, which he terms the "Unique" switch, and those who have seen it will acknowledge the term to be appropriate. The want of a simple, easy-working, and efficient switch, with no working parts to get out of order, has led to the introduction of this pattern. It consists of a key, cover, and base, all of porcelain. The base is provided with a square recess, with a small hole in the centre, in which the centre pin of the key revolves, ensuring in this manner central working of the key in the cover. The key is provided with two helical springs, wound round pins fixed into it. These springs, when the current is "on" make contact with two brass terminal plates, overlapping the side of the square recess, and connected with the circuit; when the current is turned "off" these springs occupy a similar position against two other overlapping brass plates, not in connection with the circuit. When the key is turned in the proper direction—*i.e.*, to the right—these helical springs are gradually wound up on the pins carrying them, and pass over the surfaces of the brass plates. On reaching the edges the power absorbed by the springs comes into effect, and they fly off independently of the motion of the key, producing double independent quick make or quick break of the circuit (according to their initial position) in a manner far preferable to the objectionable "loose key" method, so common in switches now in use. The make and break of the circuit by this method is

practically instantaneous, sparking being thereby reduced to a minimum. It is impossible to hold the key in any position so that sparking can wilfully occur, as is sometimes done, in switches of the "loose key" type, by thoughtless persons or servants. The switch key turns in one direction only, and a simple method is provided to prevent any possibility of the key being turned in the wrong direction. The terminal plates are kept clean by the constant rubbing of the helical springs over their surfaces, but if from dust, salt air, etc., any cleansing should be required, the key can be pulled apart from the base and the parts easily got at. There is absolutely nothing to get out of order and cause inconvenience to the user. The principle of the switch can be applied in modifications for double-pole switches and others.

An ingenious combination fitting, one of the many modifications of the "Unique" switch, is also shown. It consists of a wall socket, portable plug, and switch combined in one fitting. In construction and mode of working it is similar to the "Unique" switch before described, with this difference—the key of the "Unique" switch being replaced by a revolving centre, provided with two tube receptacles for the two contact pins of the portable plug to fit into. A cut-out is also provided if required. The combination of these important parts of an installation reduces the expense incurred by the use of separate fittings to practically the cost of one, less work being also expended in their installation.

An exhibit that will touch electrical engineers in a weak place is that of **Messrs. S. Smith and Sons**, who show a large assortment of non-magnetisable watches. The firm are well known amongst horologists as the only watchmakers who up to a short while ago had ever obtained the highest certificate of excellence in watches from the Kew authorities. We believe the particular watch tested did not vary more than three seconds under any condition in three months. This firm have at the Exhibition, just beside the Machinery Department, a stand where all kinds of watches, unaffected by magnetism, can be seen, from less than the humble guinea up to fifty or more. A continued source of interest to ordinary visitors and electrical engineers alike—for magnetism is no respecter of persons—is an ironclad watch, sticking gracefully to the side of a small dynamo, specially fitted up to show the beauties of this timekeeper, which peacefully ticks away oblivious of "lines of force." The watches are curiously termed "current-resisting," though this is a misnomer of the makers—a current would soon fuse the works—but against magnetism there is no doubt the watch is proof, and a great boon it must be to engineers of central stations or travellers on the underground railway. We are to see a small piece of apparatus for demagnetising ordinary watches at work here, for those who desire, though we are afraid there will not be much chance of a clear escape for an ordinary watch from the Machinery Hall at this Exhibition. The firm hold some very good testimonials from well-known men in electrical work.

Our illustration this week is a corner of the Entertainment Court, where Messrs. Phillips and Messrs. Laing, Wharton, and Down combine in producing effective designs for furnishing and lighting dining-rooms. Even Messrs. Laing, Wharton, and Down go so far as to provide the spider on the wall.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence ; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices :

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms :—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d.
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed " Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

THE TELEPHONE PROBLEM.

It is understood that the Duke of Marlborough holds a brief for the New Telephone Company, hence his statements in the *New Review* of this month must be taken as those of a partisan. He assumes there will be no contradiction of his sweeping denunciation that "the only line of importance we possess which has been laid in a proper manner is the Paris-London line," and asserts that his clients want "to produce as good a result all over England as is attained on the Paris-London line" ; also "there is no difficulty whatever in accomplishing this result all over England." He contends that "during the ten years of the existence of the monopoly of the telephone patents the business of the telephone in this country has been in the hands of one company, who, for various reasons, have not developed the industry." We are not going to combat these views, except so far as to restrict the condemnation to the London district. If this restriction is not made, we must say that the telephonic progress made elsewhere in two or three districts is as much as could have been expected. With regard to London, there is no good system, there never has been a good system, and under the National Company it may be doubted if ever there can be a good system. We are not even inclined to credit the London administration with empirically feeling its way. The Duke of Marlborough says, "It should be remembered that they have had to work their way from early beginnings, when the principles of the business were little understood." As a matter of fact, the early history of the National Telephone Company is one of company-mongering. The aim was purely Stock Exchange quotations. Any system of working was good enough to run the concern with, and when the men who played ducks and drakes with what ought to have been one of the finest industrial concerns in the land left the concern, their successors, who have worked like Trojans during the past few years, found it a task beyond the powers of men to repair the mistakes made by their predecessors. The action of successive Governments as regards telephony has been almost incomprehensible. No one outside of official circles has ever been able to understand the policy which purchased the telegraph system, maintained that telephony was another form of telegraphy, got the Courts to legally certify it is so, and then permitted private companies to undermine the business of the Postal Telegraph Department. Many of the Government departments are ready to expend money in promising experiments ; and, surely, from the first telephony was promising enough. The expenditure to test it to any extent was not much ; and yet the policy went forth—let private people test it, and we will be satisfied with a royalty. Good ; then if the Government now wishes to get rid of telephony—which is destined, whether the officials admit it or not, to have a very serious effect upon telegraphy—the price must be paid. There are three ways of dealing with the matter in order to obtain as perfect a system as is known. The Government can pass a Bill with as compulsory powers resting in the Board

of Trade as now rest for electric lighting. Why there should be interference on every hand with lighting, and not with telephony, is another matter which is past ordinary mental comprehension. Such powers, however, would compel a riddance of the existing London system in double-quick time. The Government might buy out the existing companies, which, unless under a compulsory purchase, means paying a high price for what is in fact almost valueless. A third way is for the Government to compete with those to whom it has granted licenses. Such competition is hardly to be suggested. It would be unjust to grant a license, allow the spending of money, and then enter into competition. The Duke of Marlborough mentions a fourth course—that the Government own all trunk lines, and permit licensees to work the towns. That plan may be workable; we doubt it. We are quite in accord, however, with the Duke when he states that a much better system can be devised than the one existing, and at a much cheaper rate. It is practically certain that if the New Telephone Company gets its Bill through Parliament and starts to work, the end of the National Telephone system in London is close at hand. The bad system cannot exist in competition with the good. The telephone cannot be said to have lost headway in London solely because of its ineffectiveness. We were compelled to refuse insertion in our last issue to complaints as to the telephone service, because under the existing law we should have had to defend a libel action, even though our correspondent and a dozen others were ready to testify to the truth and accuracy of the assertions made. The best way out of the difficulty is for the Government to do the work itself; the next best way is to support some such company as the New Telephone Company, which has proved its contention in the work done at Manchester, and so aid business and social London to attain the full benefit of one of the most wonderful and most useful inventions of the age.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

ELECTRIC TRAMWAYS.

SIR,—In your issue of February 26, you publish a letter from Messrs. Waller and Manville taking exception to my paper on "Electric Tramways on the Overhead or Trolley Wire System."

I am surprised at the tone of Messrs. Waller and Manville's letter, and at the deduction they draw in their concluding paragraph.

As an independent electrical engineer, I have been guided entirely by my judgment and experience in connecting myself with any particular system for traction work, and I, after due thought, selected the company whose system I considered the best, and whose business methods have always commanded my highest admiration.

My paper was written upon the "Overhead or Trolley Wire System," and not upon conduit systems, and I only stated what is a matter of common knowledge in reference to conduits, and with no desire to do more than justice, and to give only statements of facts in reference to all systems.

Messrs. Waller and Manville will be in a much better position and be better able to express such sentiments as are contained in their communication to you, when they have found someone besides themselves with a sufficient belief in their system to put down and work the same. In the meanwhile I can only trust that such a party will soon be found, and that they may have an opportunity of displaying their "wares" in actual service.

Thanking you in anticipation for this space in your valuable paper, I am, with best wishes for electrical systems generally (including conduits)—Yours, etc.,

W. GIBSON CAREY.

35, Parliament-street, S.W., Feb. 29, 1892.

CRYSTAL PALACE EXHIBITION.

SIR,—When next you go to see the Electrical Exhibition at the Crystal Palace you may find some amusement in buying a catalogue, looking it carefully through, and then starting to find some of the exhibits mentioned therein. You can first go and look for the electrical fire engine, then try to find the welding apparatus, then the coal-cutting machine and the rock drill, after that try the "lift," so called, no doubt, on the *lucus a non lucendo* principle, although you may not think the way good. You should then go and see the 100,000 Hedgehogs do their "high volt" transformations; then you had better go in and hear some music beautifully played by Mr. Mann's talented orchestra. This will relieve your mind, and give you an appetite for a good dinner at Bertram's *table d'hôte* before undertaking the dismal railway journey home.—Yours, etc. X.

P.S.—In my last week's letter the word "choir" should be "chair."

A DESCRIPTION AND COMPARISON OF THE METHODS OF ELECTRIC LIGHTING AT PRESENT IN USE IN LONDON.*

BY ALEXANDER B. W. KENNEDY, F.R.S., M.I.C.E., ETC.

(Continued from page 186.)

A perfect transformer ought always to give in its secondary circuit exactly the same amount of energy as that which has passed through its primary circuit. No actual transformer does this, but the efficiency of good transformers at their full load is very high—often over 90 per cent. But the full load of a house transformer corresponds to the current necessary for all the lights in the house; the transformer must of necessity be large enough to allow for this. All the lights in a house, however, are not on at once half-a-dozen times in the year; in general the maximum load in a house is less than half its full number of lamps; its average load not more than a quarter, and, of course, for many hours out of every 24 no lamps are burning at all, so that the load is zero. Unfortunately, the losses in the transformer continue all the 24 hours, whether or not there is any current passing through the secondary coil. These losses are more or less proportional to the full load for which the transformer is designed, and, taking all together, they are most serious. Such authentic statistics as I have been able to obtain show that the consumption of coal in a central station per unit passed through customers' meters is at least twice as great with the high-tension companies as with the low-tension, the figures being 17lb. to 20lb. with the one, 8lb. to 10lb. with the other. The greater part of this difference is probably due to the transformer losses. In fact, a company which has 500 transformers in its customers' houses is practically keeping as many small fires burning day and night in as many cellars at its own expense. Of course, whatever these losses may be, they do not affect the meter readings, and the customer has not got to pay for them. To remove these losses a change in method is now proposed, and I believe the London Company, at least, are taking active steps in this direction. The proposal is to remove the transformer from the customers' houses altogether, and to concentrate the transforming plant at

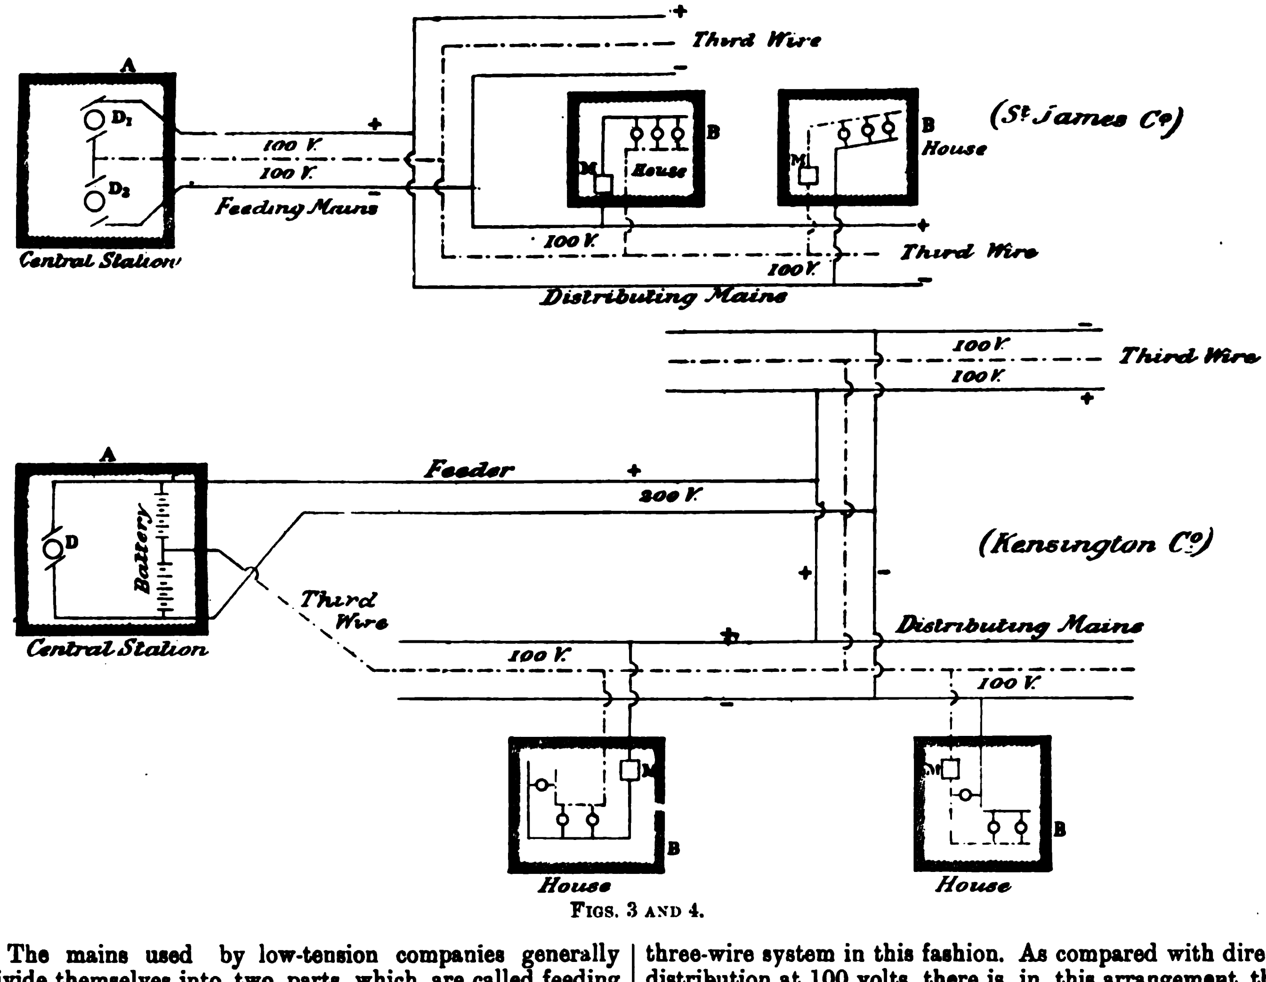
* Reprinted from the *Transactions* of the Royal Scottish Society of Arts, vol. xiii., part 1. Read May 11, 1891.

certain sub-stations, where the load will never be zero and where the number of transformers in use can be altered from hour to hour as the load varies, so that the instruments actually in use can always be worked with fair economy. This change, the wisdom of which I do not doubt, and which is being advocated most strongly by some of our best engineers, is a very far-reaching one indeed, although it seems at first to affect only a matter of detail. For, in reality, it necessitates giving up at once three-quarters of the high-tension mains, and laying new low-tension mains suitable for 100 volts pressure, from each sub-station over the whole district, exactly as in a low-tension system. If this has to be done, it is obvious that the greater part of the saving in first cost due to the use of high-tension mains disappears at once, and, as the system of "banking" transformers is as yet very little practically known, it remains to be seen to what extent it attains in practice the results expected of it. I understand that this is the system which it is proposed to use in the City of London itself, by the new company which has just been started for the purpose of lighting that district.

The low-tension companies try, as far as possible, to use bare copper strip carried on porcelain or glass insulators. This strip is enclosed in concrete culverts or iron conduits. The advantage of its use is clear, when it is remembered that the cost of the ordinary indiarubber insulation of any cable is considerably greater than the actual cost of the copper insulated. The use of bare copper, properly insulated, is quite safe up to a pressure of about 200 volts, but, of course, is impracticable with high pressures.

The systems adopted by the low-tension companies in London vary somewhat among themselves, but have certain points in common. All of them use continuous currents, and all of them but one are schemed to generate electric energy at a pressure of about 200 volts (not 100), so as to save to this extent in their mains. The distribution to houses at 100 volts, without the use of transformers or any other apparatus, is effected by a subdivision of the 200 volts into two sections or parallels of 100 volts each (by the use of what is called a third wire), and dividing the consumers, as evenly as may be, between the two sections.

Fig. 3 shows the way in which lights can be put on a



FIGS. 3 AND 4.

The mains used by low-tension companies generally divide themselves into two parts, which are called feeding and distributing mains respectively. The latter are the mains to which the house services are directly attached, and which cover the whole of the streets in the district. They are common to all systems of low-tension distribution, and will have to be used equally by alternating-current systems, if these adopt transformer sub-stations in the way just alluded to. The cost of the distributing mains is considerably very much more than half the total cost of the mains—a point to be kept in view. Feeders or feeding mains are lines radiating directly from the central station, and carrying current from it to certain fixed points, called feeding points, where they join the distributing mains. These feeders are the mains which have the largest section of copper, but they are few in number, and their total length is not nearly so great as that of the distributing mains. In a modified high-tension system, such as mentioned above, each feeder would be replaced by a line of very much smaller sectional area of copper, having a sub-station with transformers at the point where it joins the distributing mains.

three-wire system in this fashion. As compared with direct distribution at 100 volts, there is in this arrangement the very great economy that the amount of energy carried by means of a given section of copper is double, while the difficulties of insulation are not considerably increased. The three-wire system is shown in Fig. 3 as it is carried out by the St. James's Company. Two dynamos, D and D_2, are connected "in series"—that is to say, the positive pole of one to the negative pole of the next. Each dynamo generates current at 100 volts pressure. The difference in pressure, therefore, between the positive and negative mains is 200 volts. A middle, or third wire (shown by a dotted line in all the figures), is connected between the dynamos, and is carried round the circuit, the houses, B B, etc., being placed alternately on the one and the other parallel (as sketched) so that the pressure in the house is never more than 100 volts. If an exactly equal number of lamps was alight at any time on each of the two parallels, no current would pass through the third wire. But, under ordinary circumstances, the number of lamps on the two parallels is not exactly equal, and one of the dynamos will have to work a little harder than the other to make up the difference.

The use of storage batteries or accumulators is possible only upon a continuous-current system. As to the use and economy, or otherwise, of batteries, there has been very warm controversy. In London, Mr. R. E. Crompton, the engineer of the Kensington and Knightsbridge Company, has always been the leading advocate for their use, and has succeeded in very greatly improving their design. I am using them in my own district, and, while admitting that it is possible to exaggerate their advantages, I find them so useful that I could on no account be without them. The St. James's Company, on the other hand, whose conditions of working are no doubt somewhat special, scarcely use them at all, and have been very successful without them. My plan in the work of the Westminster Company has been to use them as a stand-by and regulator during work, and for taking up the whole load during the small hours of the morning, or at other times of minimum demand, thus allowing the station to be entirely "shut down." This is a matter of which the immense advantage and convenience probably appeals more to the engineer than to the consumer. I pass from 5 to 6 per cent. of the whole of the current generated through the batteries, and on that fraction I lose, on account of the imperfect action of the batteries, 15 or 16 per cent. measured in energy. I therefore pay something under 1 per cent. in total efficiency as the price for the convenience of using batteries, even supposing that they do not (as I believe they do) very much more than make up for this, by obviating the necessity for working boilers and engines at all during hours of minimum demand. The system used, and I believe originated, by Mr. Crompton is sketched in Fig. 4. It will be seen that the batteries are placed in parallel with the dynamos, and the third wire connected to the middle of the battery only, and not to the dynamos. Instead of two dynames in series, one dynamo only is used, and it generates current at 200 instead of at 100 volts.

(To be continued.)

DESIGN AND CONSTRUCTION OF DYNAMOS.*

BY T. ROOKE.

In considering the design and construction of dynamos, let us devote our attention first to continuous-current dynamos, and later we will pass on to consider some of the more prominent alternate-current machines that have of late come to the front in connection with the electrical transmission of energy.

First, then, the design of a continuous-current dynamo resolves itself into the treatment of two factors—the magnetic circuit and the electric circuit—and each of these may be considered to a certain extent separately. The commercial dynamo is always made with electromagnets. Sometimes they are self-excited, and at other times, such as

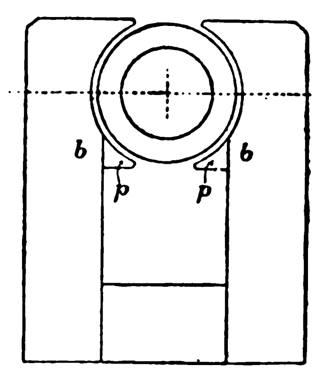


FIG. 1.

with alternate-current dynamos or high-pressure continuous-current machines, they are separately excited. The iron in a dynamo which constitutes the magnetic circuit is made up of four parts—the two limbs, the yoke, and the armature core; besides these, and the most important of all, is the air gap. These parts can easily be seen from Figs. 1, 2, 3, 4, and 5, which represent various forms of arrangement. These iron parts have first to be designed to give the highest efficiency with the least weight, and often space has to be taken into account as well. In the early

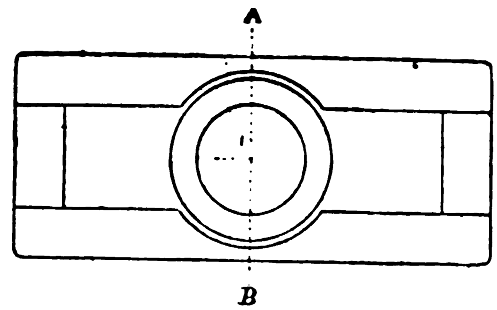

FIG. 2.

days of dynamo designing the cross-section of the armature core in cylinder machines was very small, in proportion to that of the field magnets, the copper in the armature was

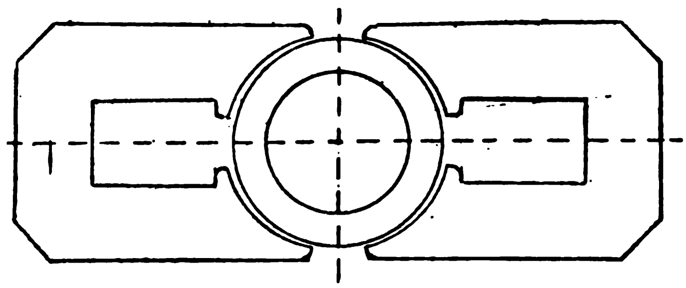

FIG. 3.

excessive, and the air gap large. Increasing the iron and decreasing the copper on the armature was found to improve the machine, it kept cooler, and did not require so

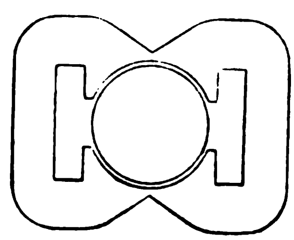

FIG. 4.

much magnetising force to give the same output. At present with most makers the ratio of the iron cross-section in the armature to that in the field magnets is between 1 to $\frac{3}{4}$ and 1 to 1.

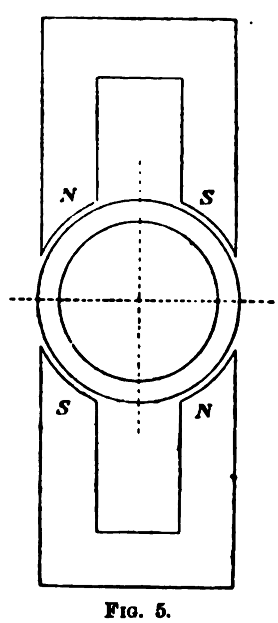

FIG. 5.

The magnetic induction at which machines usually work varies according to the quality of the iron used, but is somewhere about 15,000 lines per square centimetre in wrought-iron field magnets, which are pretty well saturated.

* Paper read before the Students of the Institute of Civil Engineers at Birmingham, Feb. 4th, 1892.

The armature is slightly under-saturated in order to keep the loss from hysteresis as low as possible. The air gap must be kept as small as is mechanically possible, for, as will be seen, it causes the greatest amount of magnetic resistance to the passage of the lines of force. For this reason, in large machines it becomes best only to wind one layer of wire on the armature; small machines have frequently two layers, but this depends entirely on the E.M.F. required.

Bearing in mind the best proportion of the armature to the field magnets, and the necessity of keeping the air gap small, the first condition to be fulfilled is that

$$E = \frac{n.C.N}{10^8}.$$

E is the E.M.F. in volts; N is the total magnetic induction in the armature, or the total useful magnetic induction; n is the number of revolutions of the armature per second; C the number of conductors counted all round the outside of the armature; and 10^8 is the ratio of the practical unit to the absolute unit of E.M.F. With these requirements it is not difficult to decide on the sectional area of the different parts of the magnetic circuit.

As regards the yoke which connects the limbs of the magnet, it is not of great consequence as to its exact shape, nor yet whether it is of cast or wrought iron, it being merely necessary to have it large enough to conduct the lines of force without throttling them; and comparing the induction curves for cast and wrought iron, Fig. 6, it will be seen that the area of the yoke, if cast iron is used, must be at least two and a half times that of wrought iron.

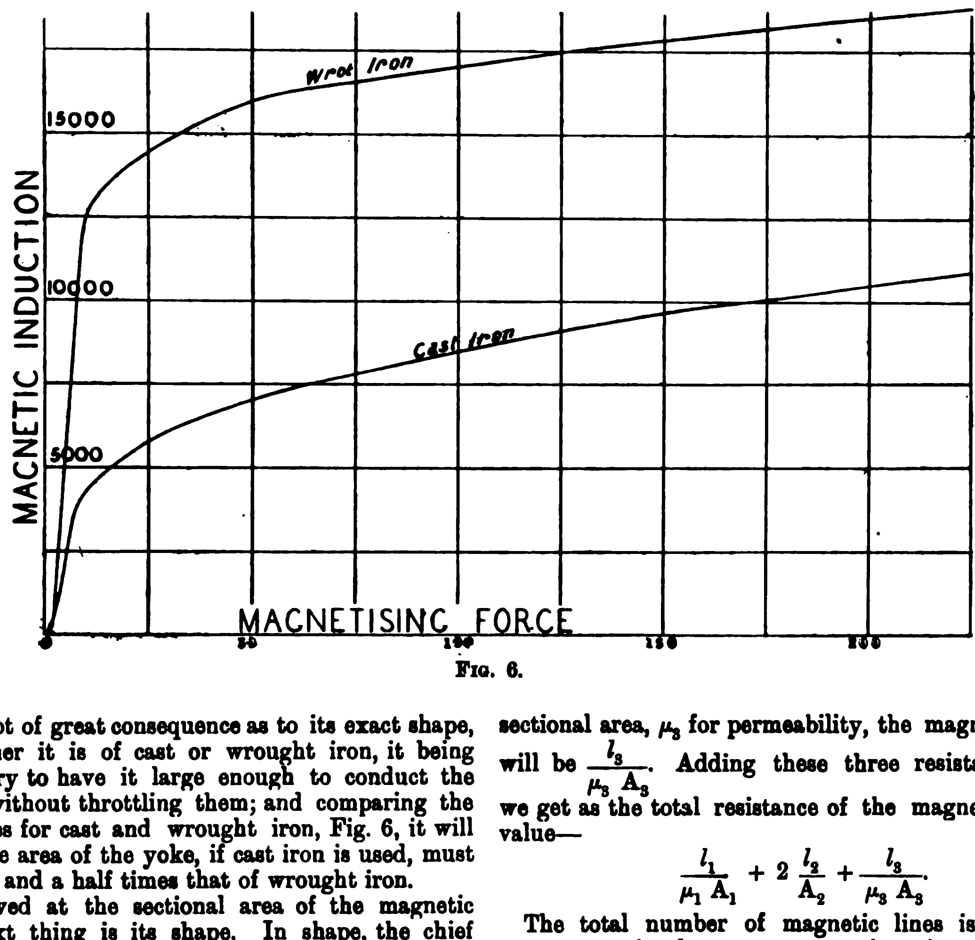

Fig. 6.

Having arrived at the sectional area of the magnetic circuit, the next thing is its shape. In shape, the chief objects to attain are cheapness of construction and convenience in winding, keeping the magnetic circuit always as short as possible. For cheapness, small dynamos are often built with wrought-iron cylinder limbs and cast-iron yoke and pole-pieces. For large machines a cylinder becomes awkward, as it takes up so much more room, and the pole-pieces would have to be so massive, so the whole magnet limb is built up of iron rails, or forged in one piece and made rectangular in section. The number of poles is generally limited to two for ordinary machines; four are sometimes used, principally for large machines giving heavy currents, although even more have been used.

Let us proceed to the winding. The wires on the armature are calculated from the formula already given, $E = \frac{n\,C\,N}{10^8}$. The most difficult part of the winding to calculate, however, is that on the magnets, and it is done as follows.

A generally applicable formula has been given by Dr. Hopkinson. Let N be the total magnetic induction through the armature necessary to induce the E.M.F., E, at the specified speed, n. The magnetising power, or magnetomotive force, of i amperes passing S times round a magnetic conductor is $4\pi S i \div 10$. N being in C.G.S. units, i has to be divided by 10, as it is in practical units. The magnetic resistance to lines of force is proportional to the length of their path and inversely proportional to the sectional area of the circuit, and the permeability of the iron. Suppose, then, the three parts of the magnetic circuit l_1 = average length of lines of force in the armature core, of which the sectional area is A_1, and the permeability μ. This part of the magnetic circuit will have a resistance of $\frac{l_1}{\mu_1 A_1}$. Similarly, for the two air gaps, if the length of path across each from iron to iron be called l_2, and the area of each polar surface A_2, the magnetic resistance these two offer will be $2\frac{l_2}{A_2}$, μ being for all non-magnetic substances equal to 1. Similarly, for the iron field magnets writing l_3 for length of path through iron from pole to pole, A_3 for sectional area, μ_3 for permeability, the magnetic resistance will be $\frac{l_3}{\mu_3 A_3}$. Adding these three resistances together, we get as the total resistance of the magnetic circuit the value—

$$\frac{l_1}{\mu_1 A_1} + 2\frac{l_2}{A_2} + \frac{l_3}{\mu_3 A_3}.$$

The total number of magnetic lines is equal to the magneto-motive force over magnetic resistance, or

$$N = \frac{4\pi S i}{10\left\{\frac{l_1}{\mu_1 A_1} + 2\frac{l_2}{A_2} + \frac{l_3}{\mu_3 A_3}\right\}}.$$

Dr. Hopkinson expressed this formula a little more generally—as follows:

$$\frac{4\pi S i}{10} = l_1 \int\left(\frac{N}{A_1}\right) + 2\,l_2\left(\frac{N}{A_2}\right) + l_3 \int\left(\frac{N}{A_3}\right).$$

For each part of the magnetic circuit he plotted a curve representing each of these functions, and from them he then plotted a resultant curve which was the characteristic of the magnetic circuit.

Having thus got a formula or curve for calculating the exciting power necessary for the field magnets of a dynamo, we must next introduce a coefficient of leakage or a correction to allow for the leakage of lines of force. This cannot be calculated beforehand with any accuracy for a

new type of machine, but must be obtained from experiment—a list of values is given for various well-known types which are most commonly met with.

CORRECTIONS FOR LEAKAGE OF LINES OF FORCE.

Type of Dynamo.	Value of v^2.
Edison-Hopkinson	1·32
Siemens	1·30
Manchester	1·49

Owing to the spreading of the induction, it is necessary to assume the air gap as having an extension beyond the polar area equal to ·8 of the distance between the armature core and the polar surfaces. The formula thus corrected becomes

$$\frac{4\pi S i}{10} = l \int \left(\frac{N}{A}\right) + 1{\cdot}6\, l \frac{N}{A_1} + l_2 \int \left(\frac{v_2 N}{A_2}\right) + \text{etc.}$$

$$\text{or} \quad \frac{4\pi S i}{10} = N\left(\frac{l_1}{\mu_1 A_1}\right) + 1{\cdot}6 \frac{l_2}{A_2} + \left(\frac{v_2\, l_3}{\mu_3 A_3}\right)$$

Having calculated thus as nearly as possible the number of ampere-turns to be wound on to the magnets of a machine, the resistance of the magnet coils and the current flowing in them is calculated in accordance with the well-known formula $C = \frac{E}{R}$.

The next thing we come to is ventilation and cooling, both of armature and magnets, for a certain amount of energy must always be lost in a machine on account of its electrical resistance, and this energy is converted into heat and must be dissipated, especially as the resistance of copper is increased rapidly by an increase of temperature.

This area for dissipating heat varies considerably, as do most other things, in different types of machines by different makers, and besides this the temperature of the place in which the dynamo has to work must be taken into account, if any fixed rule is to be given. Mr. Kapp gives, with a surface speed of 2,000′ to 3,000′ per minute, cooling surface ought to be ·8 to 1 square inch for every watt transformed into heat in the armature wires; magnets 1·5 to 1·8 square inch, but this rule cannot be fixed within considerable limits for the reasons given above. These rules are the nearest possible approximation for calculating beforehand the proper dimensions of a dynamo with a given output, but it must not be forgotten that they are only an approximation, although a close enough one for practical use. A dynamo having been completed, its performance should be recorded in such a manner that we shall be able to tell at a glance what a machine of similar carcase dimensions will give under any circumstances. First, the machine is run on open circuit, and the relation between the ampere-turns on the magnets and the E.M.F. established. Whilst running at the same speed take the greatest possible current from the armature, and, keeping this constant, take observations of the magnetising force and E.M.F., the field being weakened down step by step until it is just possible, by adjustment of the brushes, to run without sparking. Repeat the experiment for a less current in the armature; then for a smaller still, until there is a series of curves representing the relation between the magnetising force and the E.M.F. for several different values of the ampere-turns on the armature. This load diagram will tell us everything we wish to know about the magnetic circuit of a machine having these particular dimensions, and about the interference of the armature with the field circuit; it tells us the ampere-turns required for any induction on open circuit, or, in other words, the magnetising force required for the shunt only; if the machine is to be compounded, it tells us how many ampere-turns must be added to raise the E.M.F. by a required amount with any current flowing, or to compensate any armature load; it tells us how we can over-compound the machine; and lastly, just how far we can weaken the field for any load, without producing sparking.

Proceeding now to the actual construction of dynamos, let us first consider the most important part—namely, the armature. All continuous-current dynamos of practical importance at the present moment can be grouped under three headings: 1. Dynamos with drum armatures wound on the Hefner alternate principle. 2. Dynamos with cylindrical armatures wound on the Gramme principle. 3. Dynamos with disc armatures wound on the Schuckert principle.

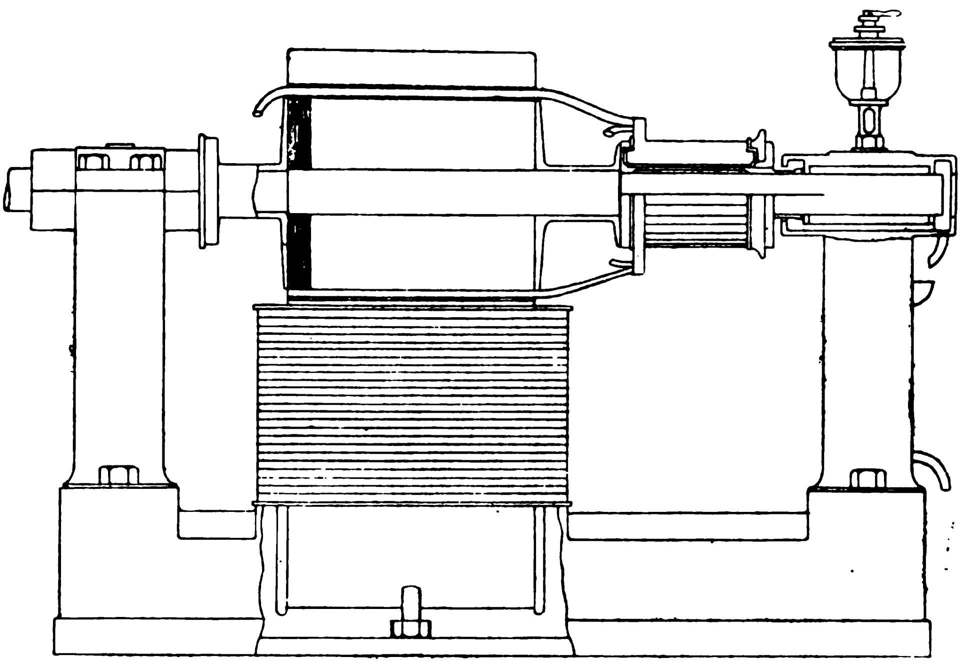

FIG. 7.—Elwell-Parker Dynamo.

The first type is represented by many makers, such as Edison, Siemens, the Electrical Construction Corporation, etc. The second type used to be represented by the largest number, but many of them now build the first type. The third type is made by the Brush Company and the Gulcher Company. From a scientific point of view all these machines, though of such wide variety of design and general arrangement, can be treated in a similar manner, and in all cases the E.M.F. in the armature is expressed by the formula $E = \frac{n\,C\,N}{10^8}$. The complication arises in determining the coefficients of leakage, depending on the shape of the field magnets. The great object in most of these armatures is to get the greatest E.M.F. generated with the least length of copper wire. Some parts of the armature are useless so far as this goes, such as the inside wires of a Gramme machine, and the end winding of a drum armature, and in the early days of dynamo design this gave rise to endless complicated forms of field magnets. It is, however, evident that all armatures are not alike in this respect. Mr. Kapp gives the following figures: The length of wire per volt generated in different armatures having the same magnetic induction

per square centimetre of armature core is, for drum 6·5in. to 16·4in., cylinder 21·8in. to 26·1in., disc (square or circular core) 26·3in. The above table shows the great superiority of the drum over any other armature. The long cylinder comes next, but is not generally employed in modern machines on account of vibration in the spindle. The tendency is to use short cores in order to reduce the distance between the bearings. Cores of equal length and diameter are often used. The flat ring which was extensively used in the early days of disc armatures is still worse as regards the length of wire required to wind it, requiring three times as much wire as the short cylinder. At one time, a very narrow and deep ring was considered the best form to be given to the core of a Gramme armature, as thereby a great expansion of polar surface could be obtained, thus bringing the whole of the wire under the direct influence of the magnets. Experience has shown, however, that this is a fallacy. For continuous-current machines used for incandescent lighting and plating, drum armatures are almost universally used, now that it is possible to ensure good insulation, which was at first one of the difficulties with this type of armature. Machines such as the Thomson-Houston and Brush are used chiefly for running arc lamps in series, as they are more easily regulated as constant-current machines. They are unique dynamos in construction, which it is hardly necessary to describe more fully here.

The construction of armatures is as follows: The old Gramme was made up of either very thin circular iron washers insulated from one another generally by varnish or paper, or else it was made up of a coil of charcoal iron wire wound on a former. This former was taken away, the iron wire core insulated by winding on tape, which was then varnished over; the coils were then wound on and the whole connected, and mounted on the driving shaft on a block of wood—the driving power was transmitted from the shaft simply by friction, and for small dynamos this was sufficient. To prevent the external wires from flying out when the armature was driven at a high speed, they were bound in by bands of brass wire passed round the armature, and insulated from the conductors by mica. Elwell-Parker Gramme armatures used to be built up of a wire core wound directly on to a brass spider, or framework of radial arms; to keep the core true, a light cut was taken over it after every two or three layers of wire had been wound on. The conductor on these armatures was driven partly by friction, partly by the coils pressing on the sides of the radial arms. It was usual to put only one layer of conductors on these armatures. Of course, there are modifications in the building of armatures by different makers; but we have only space to consider the main features of each type.

The old Pacinotti armature, which is a hollow cylinder like the Gramme, was always built of sheets of charcoal iron, insulated from one another; it has on its surface projecting teeth. The object of these teeth was partly to diminish the magnetic resistance of the air gap, and partly to act as drivers to the wire coils. It was found, however, that with the diminished clearance between the projections and polar surfaces the magnetic induction exerted by the projections on the polar surfaces absorbed a considerable amount of power in heating the pole-pieces with local currents, and no amount of subdivision could get over it. The ordinary drum armature is built up of a lot of thin discs of charcoal iron insulated from one another by varnish, paint, or paper. Sometimes they are fitted on to the square shaft, at other times they are keyed on to the shaft, and are then pressed together between end plates till they are fairly well solid, the end plates being made of bronze, or non-magnetic metal. The armature core is then turned up true with a very sharp tool, so as not to burr the edges of the thin plates, and the outside is insulated with cloth, varnish, and mica, and the coils are then wound on the armature, sometimes in one layer, sometimes in two. In a drum-wound armature with only one layer of wire the full potential of the dynamo will be between every two adjacent wires, and special care must therefore be paid to their complete insulation from one another. With two layers of wire on the armature, as in high-tension machines, the full potential of the machine is between the two layers, which are more easily insulated by a sheet of cloth and mica strips. These are close-coil armatures—that is, they have all their coils in series with one another, forming a closed circuit. Thomson-Houston and Brush machines are the two principal open-coil armatures. The shape and construction of magnets has already been discussed under the treatment of the magnetic circuit. The coils for magnetising them are wound on bobbins and slipped on. Sometimes, but not often, the coils are wound directly on to the magnet limbs, in which case they cannot be taken off except by unwinding. The commutator, or collector, is generally made as shown in the section, or is some slight modification of it. A number of copper bars having lugs left at each end are milled up so as to fit together and form a hollow cylinder. These bars are held together by insulated iron rings passed over the lugs, and are insulated from one another by mica. The whole is insulated and mounted on a cast-iron core, which is keyed on to the shaft. Bearings are generally of white metal. Brushes are held on insulated pillars, and their pressure on the commutator is regulated by means of a spring, the pressure being just sufficient to ensure good contact. They are made of pure copper. Either a number of thin sheets are laid together and one end of the layer soldered up, or they may be made of a number of copper wires soldered at one end, or, what is perhaps best for a good dynamo, they may be made of gauze. The advantage of a gauze brush is that it does not cut the commutator at all, like wire or plate brushes; the disadvantage is that on a bad dynamo which sparks a lot, the gauze rapidly wears away. In order to avoid sparking, it is necessary to adjust the brushes to the load of a machine, and this is generally done by means of a rocker fixed to the pedestal or bearing, and capable of being turned through an arc round the commutator.

Let us pass on to alternate-current dynamos. These have lately come forward very prominently in the distribution of power at a high tension, and its conversion to a low tension by means of the alternate-current transformer. In these machines alternate currents are induced in the armature coils by causing the amount of magnetic induction through them to alternately increase and decrease. Most frequently there is not simply an alternate increase and decrease, but a rapid reversal in the direction of the magnetic induction. In some of these machines, as in the majority of continuous-current dynamos, the armature part rotates whilst the field magnet part stands still. In others, however, the armature part—that is to say, the part from which the alternating current is to be obtained—is a fixture, whilst the field magnets are made to rotate. In a third class of machine, both armature part and field-magnet part are fixed, the amount of magnetic induction passing from the latter through the former being caused to vary or alternate in direction by the rotation of appropriate pieces of iron. In the older machines, the field magnets were either of steel permanently magnetised, or else electro-magnets separately excited. About 1869 began the practice of making these machines self-exciting by diverting a small current from one or more of the armature coils separated from the rest, and this current was rectified or made continuous by being passed through a crown commutator, and thence to the field magnets. These crown commutators are not generally used now, it being more convenient either to mount a small continuous-current armature on the shaft of the alternator, and thus obtain the exciting current. If the alternator runs at too low a speed for this, the exciter is driven by a belt from an exciter pulley fixed on the alternator shaft. For collecting the alternating main current of the dynamo, extremely simple means are required. In most machines where the armature is fixed, two terminals only are required; in machines with revolving armatures sliding connections only are required. Hence there is no sparking, and no adjustment of brushes with a varying load—in fact, one of the most expensive parts of a dynamo is rendered unnecessary. As it is requisite in alternate-current working to have many alternations in every second, and as mechanical considerations forbid very high speeds, it is the general practice to make this class of machines multipolar, with a considerable number of poles of alternate polarity arranged symmetrically

around a common centre. The number of complete alternations per minute in machines of different systems varies considerably from 2,500 to 12,000 or more, but about 6,000 is mostly used. The number of poles, Fig. 8, also varies from 12 to 32 or more, depending, of course, on the specified speed and number of complete periods per minute. There are two ways of coupling up the coils of alternate-current dynamos. For lighting incandescent lamps from parallel mains it is usual to connect the coils in parallel. This is low-tension distribution, such as is used at Paddington. For high-tension transformer work the armature coils are connected up in series.

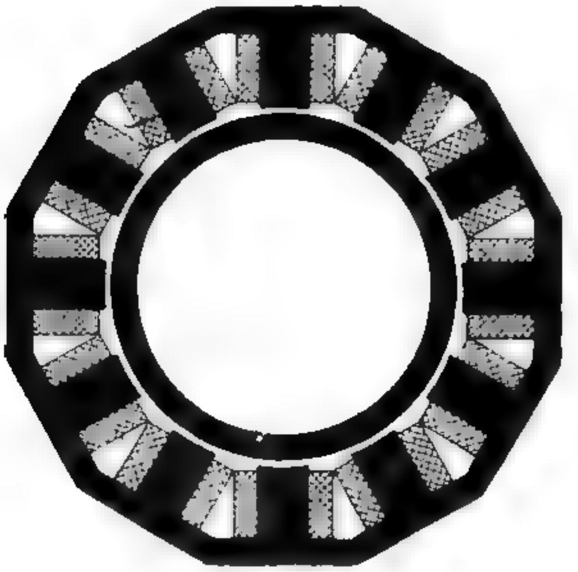

FIG. 8

With these brief remarks on alternators we must end. The mathematical treatment might be extended, as also losses from hysteresis, running in parallel and multiphase dynamos, but time does not allow.

ELECTRIC TRAMWAYS ON THE OVERHEAD OR TROLLEY WIRE SYSTEM.*

BY W. GIBSON CAREY.

(Concluded from page 208.)

In the development of the electric tramway no part presented to the pioneers difficulties comparable to those encountered in the operation of the rolling-stock, and changes in the construction of every detail have been constantly made as experience pointed out opportunities for improvements in the mechanical and electrical details. It was soon found that the methods of supporting the car bodies which were employed in animal traction would not do for electric service, and specially-designed trucks, upon which the motors were carried beneath the car bodies, were soon brought out. The matter of trucks is one of greater moment than would appear at first sight, for upon proper design and workmanship in the truck depends the smooth and safe operation of the car, while the greatest possible simplicity and accessibility of all parts is necessary for ready examination and economical repair in case of accident. This simplicity, however, is not so easily accomplished as might be supposed. The electric car has nothing to steady it like the constant pull of the horses on the drawbar in animal traction, and the fore and aft oscillation is prevented by ingenious designs in a score of trucks upon the market to-day. Out of these, however, there are scarcely half-a-dozen which are not so complex in construction that the smallest accident will necessitate an enormous amount of labour in order to get at and repair some trifling part. A truck that has to be entirely pulled to pieces in order to replace a pair of wheels will not pay in the long run, however perfect it may be in preventing oscillation and affording smooth running.

In crowded cities, on lines upon which the traffic is very large, and more or less constant, the use of very long cars is often found advisable, and in such cases bogie trucks must be used. There are, however, several considerations which qualify the advisability of very large cars. While double carrying capacity can be obtained at the expenditure of about 50 per cent. more power, the expense of hauling round very large cars nearly empty, when the traffic is light, will in most cases more than counterbalance the advantages to be gained, and on a large majority of roads a small car running during busy hours on a very quick headway is preferable. One decided disadvantage which the large car on bogie trucks possesses is the smaller proportionate weight available for the purpose of traction which it possesses. It is not practicable to gear motors to all four axles, and the universal practice is to drive such cars by two motors, each being geared to one axle of each truck, so that only half the total weight of the car is available for traction. One manufacturer has brought out a most excellent six-wheel truck with a very long wheel base, in which the axles automatically assume a position radial to any curve. In this truck almost the entire weight of the car is supported on the driving wheels, and the chief objection to the eight-wheel car obviated.

The first attempts at driving cars by electricity were made with motors mounted on the platforms and geared to the axles by means of sprocket chains. This clumsy contrivance was, however, speedily superseded by motors supported directly upon the axles and upon a flexible suspension from the truck, entirely independent of the car body. Spur gearing was used, by which the speed was reduced from about 1,000 revolutions at the armature shaft to 100 at the car axle. The limited space under the car precluded the use of large gears, and the reduction of ten to one was accomplished in two steps by means of an intermediate shaft. To-day single-reduction motors have in turn supplanted these, and the solution of the problem of gearless motors, with armatures mounted directly upon the car axles, is, perhaps, a question of the very near future. Motors of this class are, indeed, in operation to-day, but it is very questionable whether their development has reached a point at which any advantage can be gained by their adoption. The total efficiencies of the double and single reduction motors appear to be about the same, the enormous economy effected by the use of the latter being due chiefly to reduced wear. The single-reduction gears running in oil in a dust-tight casing are kept thoroughly lubricated, and are protected from the grit and flyings which formerly made the renewal of gears one of the most important items in the repair account of electric roads. Smoothless and more noiseless operation has also been effected, and it cannot be doubted that single-reduction gearing has been one of the longest steps in the direction of the perfect motor that has been made in the history of its development. Freedom from sparking under wide variations of load and change of direction of rotation is secured by making the field magnets very powerful in proportion to the armature. The output is, of course, smaller in proportion to the weight than if the magnetising effect of the armature coils were relatively greater, but in that the slight increase of weight gives better traction, this is of small importance, and as the relatively weak magnetisation due to the armature coils produces no distortion of the magnetic field, we can use fixed brushes, set radially to the commutator, which are sparkless under all conditions. The motors being series-wound, the speed with a given number of turns in the field coils, is directly dependent upon the applied E.M.F. and the resistance of the circuit, and can, therefore, be varied at will by the introduction of a graduated resistance in series with the motor. This resistance comes very little into play, but is necessary in order to avoid a jerky movement in starting. After the dead resistance is entirely thrown out of the circuit, the speed can be further increased by cutting out part of the field coils which are wound in section, the bights of the coils being led to a switch operated by the same mechanism that controls the rheostat. This weakening of the field must not, however, be so great as to allow a distortion of the field by the reaction of the armature current, or destructive sparking will ensue.

For most city work it has been found advisable to use

* Paper read before the Royal Engineers.

motors of about 30 h.p. capacity on each car. This is usually divided between two motors of 15 h.p. capacity, one being geared to each axle. In this way the entire weight of the four-wheeled car is available for the purpose of traction, and in case of an accident to one motor the car can be run into the depôt with the other, instead of being disabled, as would be the case if a single motor were used. The motors which are coupled in parallel with each other are reversed by reversing the direction of the current in the armatures. This has generally been accomplished by leading the current first to the fields of the two motors in multiple with each other, and hence through a reversing switch to the armatures, which are also in multiple with each other. The current in the fields of the two motors will, of course, with such a system of connections, be inversely proportional to the ohmic resistance of the field coils, so that an equal distribution of current between the fields can easily be secured by carefully winding them to the same resistance. As, however, these field currents are again brought together into one at the reversing switch, the currents in the armatures will depend not only on the respective ohmic resistance of the armatures, but upon the counter E.M.F.'s generated in them. Owing to differences in the iron employed in construction of the motors, it is difficult to exactly balance those, and the only practicable way of equally distributing the load between the two motors is by the employment of two reversing switches, so that the two motor circuits are entirely separate and distinct from each other. It is only by the most careful attention to such details as these that smooth and economical operation can be secured.

The current is collected from the trolley wire by means of a grooved gunmetal trolley, carried upon a trolley bar, mounted upon the roof of each car. This bar has a universal joint at its base, which allows the trolley bar to move in any direction, while springs acting upon a cam arrangement of peculiar design tend to keep the bar in a perpendicular position. The design of this arrangement is such that the upward pressure of the bar is equal whatever the tension on the springs, so that the trolley is always kept firmly pressed against the trolley wire, in spite of any variation in the height of the latter, and the flexibility of the universal joint allows it to follow any deviation of the wire away from an exact central position over the track. In the circuit between the trolley stand and the motors are interposed a fuse cut-out, which protects the motors and the wiring in case of an accidental short circuit, a lightning arrester, and the variable resistance, which is usually of iron, the rheostat being insulated throughout with mica to avoid danger from overheating. The current after passing through the rheostat is taken to the motors, and from thence through the wheels to the track and supplementary wiring, by which the circuit is completed back to the generator.

The use of a lightning arrester both on the cars and at the power station removes one very fruitful source of accidents—the long line of trolley wire, especially in country districts, being exceedingly liable to be struck by lightning, and unless some path can be provided for the escape of the discharge to earth, disastrous results to generators or motors are almost certain to follow.

Such objections as have been raised to overhead electric tramways have been made purely from a sociological point of view, and experience has invariably led to the modification or entire withdrawal of these. To the public is offers cleaner and less obstructed streets, and less wear of paving than animal traction, comfortable and well-lit cars, and rapid transit. To the financier it commends itself as cheap, reliable, and offering facilities for rapid transit, which can be given in no other way. To the engineer it presents a field for the application of motive power for moving vehicles at an efficiency exceeding that which can be given by other methods, while its extreme flexibility permits its use in places which could be reached by no other means.

We have not yet come to the end of its development. Its application upon the great railways of the world is perhaps a question of the immediate future, and its adoption in a thousand forms for the purpose of manufacture and commerce has already been begun with a success which *ensures* its rapid and universal extension.

PORTSMOUTH.

REPORT BY PROF. WM. GARNETT.

To the Electric Lighting Committee of the Borough of Portsmouth.

Gentlemen,—In accordance with your instructions, I now submit to you an estimate of capital and current expenditure and receipts for the lighting of the district specified in Schedule B of your provisional order, and of the esplanade between the two piers.

The estimate is based upon the assumption that, in accordance with the recommendations contained in my report of October 14th last, alternating currents at a pressure of 2,000 volts will be employed for the transmission of energy through the main leads. Since my report was written a very complete series of tests has been carried out on the condensing turbo-generator by Prof. J. A. Ewing, F.R.S., professor of engineering in the University of Cambridge, and a copy of his report I hope to lay before you. Prof. Ewing's results show that the turbo-generator is now as efficient as the best compound engines of the marine type, and that for light loads it stands unequalled, while in the first cost of the machine, and in the items of engine-house and foundations, it enables a very considerable reduction to be made in capital expenditure. I have therefore made my estimate in the first instance on the assumption that "turbo-electric generators" with surface condensers will be employed, and have made a supplementary estimate of the additional cost which would be involved if it should be thought desirable to employ compound condensing engines of the ordinary type, making not more than 90 revolutions per minute, coupled by endless rope gearing to alternators making 300 revolutions per minute. In this estimate I have provided for engines and alternators of the highest class of manufacture obtainable.

I have assumed that a site will be procured for the central station at which sufficiently clean sea-water for surface condensers will be obtainable at all times of the tide within a distance of 250 yards. The Grammar School has been selected as the point from which the lines of high-tension mains should diverge, and it has been assumed that the distance of the central station from this point will not exceed 500 yards. If it is impossible to fulfil this condition, the extra cost of mains will be at the rate of £3,200 per mile for the distance between the central station and the Grammar School. Concentric mains will be laid from the central station to the Grammar School, capable of carrying sufficient current for twice the number of lamps for which it is intended at present to provide. These conductors together will serve all the requirements of the station until lamps have been installed equivalent to about 17,000 lamps of 16 c.p.

The system of mains which I propose to adopt is the following: Concentric high-tension mains will be laid from the Grammar School along the principal thoroughfares mentioned in Schedule B of the provisional order and Alexandra-road. Along the Commercial-road route as far as the corner of Lake-road, and to Southsea as far as the corner of Osborne-road and Palmerston-road, high-tension mains will be laid capable of carrying about twice the current for which provision is at present to be made at the generating station. This will provide for the increased demand which will occur when the system of mains is extended to North End and the Beach Mansions. The cost of extending the lighting system in these directions, including high and low tension mains and transformers, will be at the rate of about £2,600 per mile.

The high-tension mains may be concentric armoured cables of the class manufactured by Messrs. Siemens, or concentric cables protected by a lead sheathing and surrounded by 2in. of bitumen as manufactured and laid by the British Insulated Wire Company or the India Rubber, Gutta Percha, and Telegraph Works Company. Side by side with the high-tension cable, and in the same trench, will be laid cast-iron socket pipes, 4in. in diameter, securely jointed, as in the case of a high-pressure water supply, and protected within and without by a bituminous composition. Cast-iron junction-boxes, with water-tight covers, will be inserted at intervals of about 50 yards in the course of these pipes, and through these junction-boxes the conductors may be inserted or withdrawn. The low-tension conductors, having an insulation resistance of not less than 600 megohms per mile, will be drawn into these pipes, and will thus be carried by the side of the high-tension conductors throughout the town. It will not be necessary for these conductors to carry more than 140 amperes (the current for 230 lamps of 16 c.p.) over any section of the route, and where the demand for current is very small their carrying capacity will be reduced to 70 amperes, but may afterwards be increased as required by drawing additional cables into the tubes. The low-tension conductors will be fed from the high-tension mains through transformers placed at intervals, which will ultimately not exceed 300 yards, and which will be less than this in those localities where the demand for current is very great. The transformers will be inserted in boxes in the footways, but their positions will be determined by the demands of consumers; thus, if some one consumer, or two or three neighbours require, say, current for 200 lamps, a 40-h.p. transformer will be inserted immediately opposite the premises in question, and service leads will be carried directly from the transformer for the supply without utilising the low-tension mains. The transformer will be capable of supplying current for 480 lamps, so that, in addition to supplying the premises immediately opposite, the transformer will be able to supply current (168 amperes) for 280 lamps to the secondary mains, say 84 amperes, to the right and the same to the left, to be drawn off when required

at distances not exceeding 200 yards from the transformer. As the demand for current increases transformers can be put down wherever required to supply some consumers directly and to feed into the secondary mains, and small transformers may be replaced by larger instruments when necessary. Small streets will be supplied by branches from the secondary conductors only, and towards a terminus the secondary conductors may be carried 150 yards or 200 yards beyond the ends of the high-tension mains. Should any transformer break down it would be automatically cut off from the mains, but its district would be supplied with current from the adjoining transformers with only a slight falling off of the pressure. By using separate cables for the flow and return, instead of concentric cables, for the low tension conductors, it will be possible to connect new consumers or branch circuits in side streets without interfering with the continuous supply of current to the district; but if for any purpose it is necessary to cut off the supply from the section served by one transformer, this will be easily effected by disconnecting the low-tension conductors at the neighbouring junction-boxes without interfering with the supply to any other section than that so cut off. The transformers may, with advantage, be arranged as proposed by Mr. Ferranti with gear whereby they are automatically adapted for economic working with a full load or a very light load according to the demand upon them and I have based my estimate for transformers on Mr. Ferranti's figures.

The lines along which the high-tension conductors will be carried will be as follows:

(a) Concentric mains together of ·32 square inch section from the central station by the shortest available route to the Grammar School.

(b) One concentric cable of ·1 square inch section from the Grammar School along High-street to the corner of the Grand Parade. If a supply of current is required in Broad-street, a better course for this cable will be round the Inner Camber to Broad street, and thence up High street as far as it may be necessary to carry it.

(c) One concentric cable of ·2 square inch sectional area from the Grammar School to the Pier Hotel, with a branch of ·1 square inch sectional area down King's road, to the corner of Park-lane, a second branch of ·035 square inch section a distance of 100 yards along Landport-terrace, and a third branch of ·035 square inch sectional area from the Pier Hotel, along the Clarence Esplanade, to the South-parade Pier, the main conductor being carried on from the Pier Hotel, along Southsea terrace, Western parade, and Osborne road, to the corner of Palmerston road, with a sectional area of ·15 square inch, from which corner branches of ·1 square inch section will be carried along Palmerston-road to within 150 yards of St. Jude's Church and of Clarence-parade.

(d) One concentric cable of ·2 square inch sectional area from the Grammar School to the corner of Edinburgh road, with a branch of ·035 square inch sectional area extending for 80 yards along Hampshire-terrace, and a branch of ·1 square inch sectional area extending from the corner of Commercial-road and Edinburgh-road, along Queen-street and Camden-alley to the corner of Wickham street. When there is demand for current along Ordnance-row and on the Common Hard, the Queen-street conductor may be supplied directly from the central station through a high-tension conductor laid along the Gunwharf road, Ordnance row, and the Common Hard. The main line of cable will be carried along the Commercial road from Edinburgh road to Lake road with a sectional area of ·15 square inch, and from Lake-road to All Saints' Church with a sectional area of ·1 square inch.

The low-tension, or secondary conductors, laid in pipes as above described, will follow the same routes as the high-tension mains, with the following exceptions:

1. Wherever necessary the secondary conductors will be carried beyond the ends of the high tension mains to distances of 150 yards, or, in some cases, 200 yards. The secondary conductor will thus be carried to the dockyard gates, along the whole length of Hampshire and Landport terraces, to the corner of Broad street, Portsmouth, and along the Palmerston-road to the corners of Marmion-road and Clarence-parade.

2. Along the Clarence Esplanade branch low-tension conductors of only ·018 square inch sectional area will be laid in 1¼in. wrought-iron barrel. Very small transformers will be used on this section, and the current will be cut off from the whole circuit, except when the lights on the Esplanade are required. (Should a large supply of current be required for the Clarence Esplanade Pier it will probably be best to provide an entirely separate main for its supply from the central station, with telephonic communication, whereby instructions would be transmitted to the station in the event of the pier lights being required at unusual hours.)

3. No low tension conductors will be required along the route of the main cables from the central station to the Grammar School, or from the Grammar School to the corner of King's-road and to Victoria Hall, or along a portion of Edinburgh-road, unless it is desired to provide public lights along these roads.

For the purpose of public lighting in the streets, instead of arc lamps, placed at distances of 50 yards or more, I prefer to employ "high efficiency" incandescent lamps of 150 c p , fixed at distances of about 30 yards. These lamps would be supplied directly from the low-tension conductors, and two of them would require about the same power as a single arc lamp. They would need to be more frequently renewed than ordinary incandescent lamps, and this has been taken into account in the estimate of annual expenditure. A 16-c.p. lamp should, except on the Esplanade, be carried in the same lantern with the 150-c.p. lamp, and should be switched on, in the place of the larger lamp at 11 p.m., thus enabling the streets to be lighted all night, at about the same cost as would be required to maintain the larger lamps until midnight. If incandescent lamps are adopted, only very light columns will be required for their support, and they will need no attention until they require renewal, while the present lamp columns may be used in most cases. Arc lamps require expensive standards, and cost about £4 each per annum for carbons and trimming, if burning until midnight only.

As the conductors along the Clarence Esplanade will be used for public lighting only, so that all the lamps connected with them will be switched on and off together, and as no small lamps are required in this situation during the whole night, it will be convenient to switch the whole of the lights on and off simultaneously by means of a high-tension switch at the point at which the Esplanade conductors branch from the mains near the Pier Hotel. On a public promenade the lighting up simultaneously of 90 powerful lights will be effective.

For the lights along the Clarence Esplanade arc lamps are less unsuitable than in the streets, but high-power incandescent lamps would meet the requirements of the situation. If it is decided to use only a few arc lamps in special situations it seems unnecessary to provide a separate plant for arc lighting, or even to lay down a special set of mains supplied with continuous current through a rectifier, since alternating-current arc lamps may be employed, as at Newcastle, and fed from the high-tension mains through transformers, which reduce the pressure to 60 volts. One transformer may be employed for a group of seven lamps. A supplementary estimate is appended to provide for arc lights on the Esplanade and in the principal roads if desired.

Though the capital required for the installation of 8,800 private and 200 public lamps is estimated at only £40,000, it is desirable that borrowing powers should be obtained for a much larger sum, in order to enable extensions to be made to the system from time to time as the public may demand, without renewed application to the Local Government Board.

No item has been included for meters, as arrangements can, if desired, be made with the manufacturers of meters to supply them and maintain them in working order at an annual charge which would be completely covered by the rental per meter paid by consumers. If it is preferred that the meters should be purchased, the rental would suffice to pay interest on the capital outlay, and to create a sinking fund for its repayment within 10 years.

The cost of the site is another item not included in the capital estimate, as I have not yet learned whether land already the property of the Corporation will be available for the purpose, and without due information it is useless to estimate the cost of a site in a district where the value of land varies enormously with a change of only a few yards in its situation.

No allowance has been made for the renewal of lamps used for lighting the central station, inasmuch as the blackened lamps taken down from the street columns may be used in the engine-room until they are broken up.

So long as the number of private lamps wired is less than the equivalent of 8,800 60-watt lamps, the income will be less than the amount estimated below, and the expenses will also be less, but not in the same proportion. There appears, however, to be a reasonable margin to meet this difference, and if the public lighting is undertaken at once the installation may be expected to pay its working expenses and interest on capital actually invested as soon as the number of private lamps wired exceeds 5,000.

CAPITAL.

Estimate for High Speed Generating Plant and Incandescent Lamps for Public Lighting.

Buildings, including chimney shaft, boiler-room, engine-room, hot-well, offices, stores, coal stores, etc.	£5,000
Travelling crane to lift four tons	200
Cast-iron 12in. pipes for condensing water, 300 yards run laid from sea to engine room	400
Five Lancashire boilers, each 30ft. by 7ft. 6in., constructed for a working pressure of 160lb. per square inch, fixed in position with foundations, flues, fittings, firing tools, and all accessories	4,500
Three 150-unit generators, one 100-unit generator and one 75 unit generator for the production of alternating current at 2,000 volts, with condensers	7,000
Two duplex feed pumps, each capable of supplying all the boilers at full load, with steam and water pipes fixed and connected	200
Main and exhaust steam pipes with brass valves arranged so that any generator can be supplied from any boiler and exhausted into any condenser, pipes and connections between condensers and main suction and delivery pipes for circulating water, steam and exhaust pipes to auxiliary engines driving circulating and air pumps, alternative exhaust pipes carried through roof to enable any generator to be used as a non-condensing engine, and duplex arrangement of feed-water connections, all high-pressure branch steam-pipes being of copper	2,000
Main switches, fuse boards, voltmeters, ampere-meters, resistance coils, transformers for pilot lamps and lighting engine and boiler rooms and offices, with lamps and fittings for the same	800
Economiser, fixed	500
Tools	250
Spare armatures, bearings, and other parts	500
Transformers for 460 units, each transformer being wound with three separate wires in both primary and secondary	

circuits, so arranged that they can be coupled by automatic gear in "series" for light loads, and in "parallel" when the load is sufficiently increased, at £7. 5s. per unit, to include street boxes and fixing	3,335
Mains—Concentric mains of ·32 square inch sectional area from central station to Grammar School	900
High-tension mains, as above specified, exclusive of Clarence Esplanade	3,700
Low-tension mains, including trenching and making good the roads and footways, laying cast-iron pipes with junction-boxes and cables, as above specified	5,200
High and low tension mains, with junction-boxes for Clarence Esplanade	900
Lamp columns. Ninety new columns with lanterns fixed complete, and lanterns and connections to 110 gas columns	*800
Office furniture and equipment	200
Contingencies, 4 per cent.	1,600
Engineers, clerk of works, quantity surveyor, etc.	2,000
Total	£39,985

* This estimate provides only for the plainest possible type of lamp columns on the Esplanade.

RECEIPTS.

Private lighting, 352,000 units at 6d.	£8,800
Public lighting, 120,000 units at 4d., to include renewals of incandescent lamps	2,000
	£10,800

EXPENDITURE.

Coal, 472,000 units, at ·9d. per unit sold				£1,770
Wages at central station, 52½ weeks at £12. 12s.				675
Oil, waste, and other stores, at ·15d. per unit				295
Salaries				500
Law and office expenses				300
Queen's taxes on central station (£200 rental)				5
Local rates—water				50
Insurance (boiler insurance only)				50
Wages for labour in streets				150
Renewal of street lamps				350
Depreciation and repairs:				
Buildings, on £5,000 at 2½ per cent.	£125	0	0	
Running machinery, boilers, economiser, etc., on £12,200 at 7½ per cent.	914	0	0

say,				2,112
Interest on £40,000 at 3½ per cent				1,400
				7,639
Balance				3,161
				£10,800

In the above estimate the cost for excavation, for laying and jointing cast-iron pipes, and for making good the roads and footways, as well as for ordinary builders' work, has been taken at prices at which it is believed that the work could be easily done by local contractors, under the supervision of your engineers. If the contractors for the electrical plant and conductors are required to tender for this work, it is probable that an addition of about £1,000 will be made by them to cover risk and cost of supervision.

If 45 alternating-current arc lamps are used on the Clarence Esplanade the extra capital cost will be about £1,000, and the extra charge on revenue will be about £155 if the lamps are burning until midnight only, but this will provide no light between midnight and sunrise. If the same lamps are replaced at 11 p.m. by 32-candle lamps burning till sunrise, the extra cost on revenue account will be about £180 per annum.

If the whole of the public lighting is carried out by 100 alternating-current arc lamps burning till 11 p.m., and then replaced by 32-candle lamps burning until sunrise, the extra cost on capital account will be about £2,200, and on revenue account about £400 per annum.

If 100 continuous-current arc lamps are employed for street lighting, with rectifiers as proposed by Mr. Ferranti, the extra expenditure on capital will be £3,200 beyond the above detailed estimate and on revenue account about £480 per annum.

If an entirely separate arc lighting plant is employed, consisting of two 75-unit continuous-current generators (one being spare), one of the 150-unit plants may be replaced by a 100-unit plant, and the extra expenditure on capital will amount to about £4,000 beyond the first estimate given, but the extra expenditure on revenue account will be no greater than with the alternating currents and rectifier, as there will be no loss in transformation.

If slow-running compound condensing engines of the highest class, making from 75 to 90 revolutions per minute, and coupled by endless rope gearing to slow-running Ferranti or other alternators are employed, the extra on the foundations and buildings of the central station and crane will amount to about £2,500, and the extra on the engines and dynamos to about £5,000. The total capital expenditure will then be £47,435, and annual expenditure £8,082. If 100 continuous-current arc lamps be used for public lighting and supplied from a separate plant, driven by slow-running engines, the capital expenditure will be about £52,450, and the current expenditure about £8,600 per annum. Slow-running compound engines may be obtained at a cost much below this estimate, but the extra on the buildings and foundations cannot be avoided.

I shall be glad to learn the wishes of the committee with respect to the employment of arc lamps or incandescent lamps of high power for public lighting. With respect to this point, it may be mentioned that only incandescent lamps will be suitable for small streets, and very little extra cost would be incurred if incandescent lamps were at first employed in the main thoroughfares and supplied with current from the ordinary low-tension conductors, and were subsequently replaced by a complete system of arc lighting, and themselves relegated to the less important streets.

By the system proposed the public lights would afford work for the generating plant and utilise the mains pending the acquisition of a sufficient number of private consumers to render the private lighting plant remunerative.—I have the honour to be, gentlemen, your obedient servant, WILLIAM GARNETT.

SUMMARY OF CAPITAL EXPENDITURE.

High-speed Plant.

Interest	1,400
	£7,634

Southsea, December 26, 1891.

ELECTRICITY UP TO DATE.

This formed the subject of an interesting lecture recently delivered at the Peel Park Museum, Manchester, by Mr. Percy A. Ramage, of Messrs. Mather and Platt's Iron Works, Salford. The lecture was delivered under the auspices of the Salford Corporation, and the chair was occupied by Councillor F. W. Roe Rycroft. The lecturer referred to the various theories which had been entertained with regard to the nature of electricity, and said that it was to Faraday that they largely owed their knowledge of the subject. The greatest advance in the use of the power had been made in producing heat for domestic purposes, and it was even used to a slight extent in heating railway carriages. The lecturer reviewed the operations connected with the telegraph, the telephone, and the phonograph, and said that such progress had been made in connection with the former instrument that six or even more messages could be sent over one line at a time. He referred to the extension of electric lighting in London and Manchester, and to the new electric railway in the metropolis, of which he gave a lucid and interesting description. In conclusion, he said that there was still a vast deal to be done in electrical engineering in saving the amount of energy drawn from coal, and it was to that object that scientists were devoting their best attention. The lecture was illustrated by numerous large diagrams, and was appreciatively listened to by a crowded audience. The proceedings were closed by a vote of thanks to the lecturer and chairman on the motion of Alderman Robinson, seconded by Councillor Phillips.

COMPANIES' MEETINGS.

TELEGRAPH CONSTRUCTION COMPANY.

The twenty-eighth ordinary general meeting of the Telegraph Construction and Maintenance Company, Limited, was held on Tuesday at the offices, 38, Old Broad-street, under the presidency of Mr. Philip Rawson, J.P., in the absence of Sir George Elliot, M.P., who was stated to be now on his way from Egypt.

The **Chairman**, in moving the adoption of the report and

accounts, said the latter showed a prosperous condition of the Company. There was a net result of £85,199, after charging interest on debentures. To this sum was to be added £61,000, brought forward from the last account. An interim dividend was paid in July last, which absorbed £22,410, leaving £124,314. Of this sum the Directors proposed to distribute a dividend of £1. 16s. per share, being at the rate of 15 per cent., and making a total dividend of 20 per cent. on the year. This would leave £57,084 to be carried forward to the next account. From the report it would be noticed that the work done during the year had been considerable. Repairs had been carried out on the Brazilian Submarine Telegraph Company's cables in the vicinity of Lisbon and Madeira, and on the Direct United States Company's cable on the coast of Nova Scotia. A duplicate cable had been laid for the Eastern Extension Telegraph Company between Madras and Penang, and a triplicate cable for the Eastern Telegraph Company between Aden and Bombay. A cable had also been laid for the Great Northern Telegraph Company between Oye, on the France coast, and Fanoe, on the coast of Denmark. During the year a length of 5,132 knots of telegraph wire had been insulated for submarine and land lines. The Gutta Percha Company was doing very good business, and, altogether, he considered the shareholders of the Company were to be congratulated on the position.

The motion was seconded by **Mr. George W. Campbell**, and carried.

NORTHAMPTON ELECTRIC LIGHT COMPANY.

A general meeting of the members of the Northampton Electric Light and Power Company, Limited, was held at the Guildhall, Northampton, last week, Mr. S. L Seckham, chairman of directors, presiding. The report stated that the mains already laid amounted to 2,800 yards, and that there were in use or being installed no less than 3,400 lights of 8 c.p. This, as Alderman Randall explained, was 1,400 lights in excess of anticipation. In consequence of the large increase in the business, it had become imperatively necessary to enlarge the machinery at an early date. The year's trading showed a loss of £461. 7s. 2d.; but that, it was explained, was owing to the expenses of a year's working being set against an income of only about three months. Councillor Cleaver and Mr. W. Tomes were re-elected directors, and Mr. Hull was re-appointed auditor. Several directors and members spoke most highly of the prospects of the Company.

ACTIEN GESELLSCHAFT: MIX AND GENEST, BERLIN.

At their last meeting the Directors of the above Company considered the balance-sheet, which showed, after writing off the usual for the depreciation on stock, a gross profit of 160,306 marks, as against 69,668 marks of the previous year. They proposed to the shareholders to write off on plant, tools, etc., 17,428 marks, and on patent account 44,634 marks, as against 4,159 marks written off patent account in the year 1890, and then to pay a dividend of 6 per cent. The extraordinary amount written off patent account, which represents nearly 4 per cent. on the paid-up capital, is far in excess of the amount written off in former years, consequently there will in future only be a nominal amount to write off annually, and so leave a larger net profit available for dividends. Both their factories are now working at high pressure, and the orders in hand are much in excess of what they were for the corresponding period of last year.

COMPANIES' REPORTS.

CITY OF BATH ELECTRIC LIGHTING AND ENGINEERING COMPANY.

Directors: Lieut-Colonel Theophilus Vaughton, J.P., Major-General J. Gordon Jervois, R.E.; Messrs Harry Newson Garrett, C.E., Alfred Pitman, Thomas Octavius Callender, Emile Garcke, Henry George Massingham, Ernest Pitman, C. J. Wharton. Secretary, Wm. Jeffery, 2, Northumberland-buildings, Bath.

Report of the Directors presented at the first annual general meeting of the Company, held at the works of the Company, Dorchester-street, Bath, on Saturday, Feb. 27.

The Directors have pleasure in submitting the first annual report and statement of accounts. The number of shares allotted is 3,246, upon which the sum of £31,981 has been paid. The result of the first year's operations of the Company is, in the opinion of the Directors, satisfactory. During the year the supply of current for incandescent lighting increased by 50 per cent., and the current is now supplied nightly to 102 arc lamps and 5,000 glow lamps. The gross profit amounts to £1,626. 8s. 5½d., and after deducting Directors' fees, salaries, and other standing charges, there remains a net balance of £585. 19s. 1½d. The Directors recommend that a dividend at the rate of 4 per cent. per annum (absorbing (£556. 16s.) be declared on the paid-up capital. The Directors have not written off any amount for depreciation, but all repairs and renewals have been charged to profit and loss account, and care has been taken to keep up all the plant to its original working efficiency. The engineer-in-chief, Mr. Ollson, reports: "In accordance with your request, I have pleasure in informing you that the plant is in good working order. The engines and dynamos have been kept in thorough repair, and the mains, both for arc and incandescent lighting, are in perfect order." The Directors propose, in order to meet future depreciation of machinery, and to provide for exceptional outlay in any one year, to constitute a renewals fund, to which the balance of revenue, after providing for the dividend above mentioned, will be carried. The electric light is finding increasing favour in the city, as is evidenced by the many fresh installations. Among other buildings, the Bath and County Club has been fitted throughout. Deputations from various towns have visited Bath during the past year, for the purpose of inspecting the Company's works and lighting arrangements. The general testimony is that the central station is one of the most successful yet carried out, and the only improvement suggested by the deputations is that in some parts of the city additional arc lamps should be erected. The Directors anticipate that the coming year will show even better results, and they are giving special attention to the question of reducing the initial charge for installing the electric light. They are also considering the question of giving a day and night supply of electricity.

KESWICK ELECTRIC LIGHT COMPANY.

The annual report of the Directors of the Keswick Electric Light Company has been issued. During the past year they have experienced great difficulties in having to run the station with plant only partially supplied with water power, in consequence of which considerable expenditure has been incurred in providing steam power to supply the deficiency. The business of the Company continues to increase, and in order to meet the requirements it has been found necessary to make considerable extensions in the main-wiring, the advantages of which to the Company are not fully felt. Notwithstanding these difficulties and the extraordinary working cost, the Directors have satisfaction in presenting a statement of accounts which shows a balance upon the year's working

of £87. 8s. 5d., which, being added to the balance left over from the previous year, leaves a sum of £122. 4s. They propose the payment of a dividend of £3 per cent., which will leave £44. 10s. 7d. to be carried forward to the next account. The receipts from consumers amount to £541. 11s. 2d.

NEW COMPANIES REGISTERED.

Pioneer Telephone Company.—The Pioneer Telephone Company, Limited, has been formed with a capital of £100,000 in shares of £10 each, for the purpose of acquiring certain rights and interest secured to the Electric and General Investment Company, Limited, under which the undertaking of the Mutual Telephone Company, Limited, in Manchester, may be acquired as a going concern. It has also been formed for the purpose of providing the necessary capital for the New Telephone Company, Limited, the objects of which are the acquisition, establishment, and working of telephone exchanges throughout the United Kingdom under license. Seven thousand five hundred shares were offered for subscription. The officers are as follows: Board of Directors, the Duke of Marlborough, 3, Carlton House-terrace, S.W., Colonel the Honourable Oliver Montagu, 3, Mount-street, W., Charles Praed, Esq., Lloyds Bank, Limited, F. E. Savory, Esq., West Suffolk County Club, Bury St. Edmunds; bankers, Lloyds Bank, Limited; brokers, Messrs. Foster and Braithwaite, 27, Austin-friars, E.C.; solicitors, Messrs. Dawes and Sons, 9, Angel-court, E.C.; auditors, Messrs. W. H. Pannell and Co., 13 and 14, Basinghall-street, E.C.; secretary, J. Cecil Bull, Esq.; offices, Nos. 1 and 2, Great Winchester-street, London, E.C.

BUSINESS NOTES.

City and South London Railway.—The receipts for the week ending 28th February were £834, against £754 for the corresponding period of last year.

Eastern Telegraph Company.—The traffic receipts of this Company for February were £58,284, as against £59,155 for the same period of 1891, a decrease of £871.

Submarine Cables Trust.—The coupon due in October last of the Submarine Cables Trust will be paid in full on and after the 15th inst. by Messrs. Glyn, Mills, and Co.

Eastern Extension Telegraph Company.—The receipts of this Company for February amounted to £39,002, as against £43,883 in the corresponding period, showing a decrease of £4,831.

PROVISIONAL PATENTS, 1892.

FEBRUARY 22.

3423. **Improvements in telephones.** Sir Charles Stewart Forbes, Bart., 21, Finsbury-pavement, London.

3427. **A new carbon electrode for electric arc lighting, to be called the electric torch.** Carl Anton Johannes Hugo Schroeder and Heinrich Eugen Richard Schroeder, Whetstone House, Heslop-road, Balham, London.

3443. **Improvements in electric arc lamps.** George Hughes, 38, Chancery-lane, London. (Charles Henri Octave Japy and Oscar Helmer, France.) (Complete specification.)

FEBRUARY 23.

3472. **Improvements relating to incandescent lampholders.** Reuben James Bott, 9, Park-place-villas, St. Mary's, Paddington London.

3488. **An improved method of coiling up conductors of portable electric lamps.** Alexander Charles Hamilton, 41, Lennox-gardens, Chelsea, London.

3512. **Improvements in the process of electrolysing alkaline salts.** George Dolor Davis, 25, Bedford-place, Russell-square, London.

3513. **Improvements in diaphragms for electrical cells.** George Dolor Davis, 25, Bedford-place, Russell-square, London.

3514. **Improvements in the process of electrolysing alkaline salts.** George Dolor Davis, 25, Bedford-place, Russell-square, London.

3521. **Petroleum lamp with electrical igniting device.** Oliver Imray, 28, Southampton-buildings, London. (Carl Wasmuth, Germany.)

3523. **Improved galvanic element.** Oliver Imray, 28, Southampton-buildings, London. (Carl Wasmuth, Germany.)

3538. **Improvements in distributing and controlling electric currents in mines or other dangerous places.** Robert John Charleton and Henry Walker, 46, Lincoln's-inn-fields, London.

3542. **Improvements in telephone apparatus.** Henry Harris Lake, 45, Southampton-buildings, London. (William Gray, United States.) (Complete specification.)

3560. **Improvements in trolley-wire hangers and other appliances for use in overhead electric railway systems.** Smith W. Kimble, 55, Chancery-lane, London.

3561. **Improvements in trolley wheels for electrically-propelled vehicles.** Smith W. Kimble, 55, Chancery-lane, London.

3562. **Improvements in the construction and mounting of electrical connecting devices upon their non-conducting supports.** Smith W. Kimble, 55, Chancery-lane, London.

3569. **Improvements in the glass chimneys, globes, and shades of electric and other lamps.** Albert Cay, trading as James Stevens and Son, and also as Stone, Fawdry, and Stone, 7, Staple-inn, London.

3572. **Improvements in apparatus for electrically operating or controlling type-writing machines, type-setting machines, or apparatus for recording, indicating, or signalling.** Archibald FitzGerald Law, 45, Southampton-buildings, London. (Edward FitzGerald Law, Russia).

FEBRUARY 24.

3595. **Improvements in shades and reflectors for incandescent electric lamps.** Frederick Moore, 57, Colmore-row, Birmingham.

FEBRUARY 25.

3654. **Improvements in electric burglar alarms.** Ernst Richter, 70, Market-street, Manchester. (Complete specification.)

3662. **An improved method of electric traction: underground system.** William Robert Clapcott Wakley, 23, Princes-square, Bayswater, London.

3707. **Improvements in electric arc lamps.** John Clayton Mewburn, 55, Chancery-lane, London. (Paul Sée, France).

3719. **Improvements in apparatus or switches for controlling electric currents.** Arthur Basil Burnand, 47, Lincoln's-inn-fields, London.

3724. **An improved electric arc lamp.** Hermann W. Sander and Martin D. Memmell, 55, Chancery-lane, London.

FEBRUARY 26.

3758. **Improved holder for incandescent electric lamps.** William Frederic Parkinson, 7, Kemys-street, Griffithtown, near Newport, Monmouth.

3801. **Improvements in electric bells.** Leslie Watt Winnall and William Howard Winnall, 4, South-street, Finsbury, London.

FEBRUARY 27.

3873. **Improved insulating media for electrical conductors.** Henry Cornelius Donovan, 53, Chancery-lane, London.

3875. **Improvements in and relating to electric motors.** Carl Coerper, 45, Southampton-buildings, London. (Complete specification.)

3881. **Improvements in electrical accumulators.** Karl Kahabka, 4, South-street, Finsbury, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1891.

3748. **Electrical insulators.** McLean.
4860. **Heating and welding by electric arc.** Howard.
5712. **Insulating electrical conductors.** Pitt. (Davidson.)
5713. **Insulating electrical conductors.** Pitt. (Davidson.)
5714. **Insulating electrical conductors.** Pitt. (Davidson.)
5835. **Electrical measuring instruments.** Jones.
5918. **Electric batteries.** Harris and Power.
6372. **Electric time-calls.** Varley.
12982. **Electric time-check.** Wetherfield.
13942. **Electric circuits.** Parker and others.
18093. **Electric fire alarms.** Elkington. (Compania Electricista contra Incendios).
18348. **Distribution of electricity.** Parker and others.
21728. **Electric arc lamps.** Waterhouse.
22482. **Voltaic cells.** Lake. (Weston.)
22820. **Telephones.** Furtado and others.

1892.

106. **Electric switches.** Sturge.

NOTES.

Salisbury.—Tradesmen at Salisbury are complaining of the insufficient lighting of the streets.

Telephone Bills.—No less than 112 separate opponents desire to appear in opposition to the Telephone Bills.

Physical Society.—Prof. Perry will read a paper on "Choking Coils," at the Science Schools, South Kensington, at 5 p.m. to-day (Friday).

Birmingham Cars.—The new cars designed by Messrs. J. E. H. Gordon and Co. for the Birmingham line are ready, and will be tested shortly.

Oil Engines.—Prof. Wm. Robinson continues his Cantor lectures on "Oil Engines" before the Society of Arts on the next two Monday evenings.

Electric Spark Photography.—Mr. C. V. Boys will lecture on the above subject at the Lecture Theatre, South Kensington Museum, on Saturday, at 3 p.m.

Edinburgh Tramways. — The Edinburgh Town Council have unanimously agreed to purchase the tramways on the expiry of the company's lease in June next.

Assessment of Telephone Wires.—At South Stoneham the assessment for the telephone company is at the rate of £1 per mile net rating throughout the union.

Explosion.—The following is from the *Bulletin International*: "The boiler at the Garnot station at Provins having exploded, the distribution of light is suspended." No doubt it would be.

Deputations.—Under the guidance of Mr. W. H. Preece and Mr. MacGeagh, a large party, many of them members of the Commissioners of Sewers, visited the Crystal Palace Exhibition last week.

Electric Cooking.—A room in the South Nave of the Crystal Palace Exhibition has been fitted by Messrs. Crompton with electric heaters; and its advantages will be explained daily by Mr. H. J. Dowsing.

Electric Transmission of Power.—M. F. Kéramon begins a historical *résumé* of the developments of transmission of power by electricity in *Cosmos* for March 5. The experiments of M. Marcel Deprez occupy the first number.

Blackpool.—The Electric Lighting Committee have decided to recommend the extension of the Promenade lighting. It is also intended to light some of the streets, and to supply the shops and places of business that require the light.

Engineers' Exchange.—Mr. Reginald Bolton, of the Institution of Civil Engineers, advocates the establishment of a Central Engineering Exchange on the model of the Coal and Corn Exchanges, where on given dates members might certainly be found.

Crystal Palace Exhibition.—It may be interesting to our readers to learn that the admissions to the Palace during the present electrical exhibition have been to date about 41,000 more than during the corresponding period of the exhibition held 10 years ago.

Birkdale.—The Local Board of Birkdale (near Southport) have had complaints of the insufficiency of the gas supplied by the Southport Corporation. The suggestion by Mr. Barrett, that the Board had better adopt the electric light, met with the hearty support of the chairman.

College Dynamo.—The Edison dynamo which is well known to so many electrical students at Finsbury, has been replaced by a larger Kapp machine. We believe that the Edison machine, which is in good condition (110 volts and 150 amperes), is for disposal for a nominal sum.

Bristol.—The plans embodying a first plant of 1,500 h.p. are now practically complete, and it is to be expected that tenders will be invited before long. The arrangements for coal feeding and so forth will make the station almost automatic, only two attendants being required.

Distribution of Electric Lighting.—At the meeting of the North-East Coast Institution of Engineers and Shipbuilders, to be held at West Hartlepool on Thursday, March 17, a paper on "The Distribution of Electricity for Lighting Purposes" will be read by Mr. J. Brentnall Duckitt.

Manchester Deputation — The Manchester Gas Committee are now in London. On Wednesday they visited the South London Railway generating station, subsequently visiting the Crystal Palace, their visit being private. The object is mainly to see electrical plant in operation.

House of Commons Lighting.—Whilst the electric light has been applied in the House of Commons at an annual cost estimated for the coming year at £1,800, the gas bill increases rather than diminishes. Last year it was £3,000; for the coming year it is believed it will not be less than £3,200.

"Electrical World."—Dr. Louis Bell, who has been editor of our esteemed contemporary the *Electrical World* for the past two years, has retired from that position to undertake more direct engineering work. Mr. Carl Hering, who has long been connected with the paper, takes charge of the technical department.

Comparison of Cost.—The detailed accounts published of the lighting of the municipal buildings of Vienna, where both gas and electricity are used, shows that, per hour of lighting, the price of electricity is 46 per cent. higher than gas. It is expected that considerable greater economy will be experienced during the coming year.

Bournemouth.—At the last meeting of the Bournemouth Town Council, the General Purposes Committee reported that the Board of Trade had consented to grant a license for the lighting of the pier by electricity. The committee recommended that the necessary application be made for the license. The report was adopted.

Royal Meteorological Exhibition.—An exhibition will be held by the Royal Meteorological Society from Tuesday, 15th, to Friday, 18th inst., at the Institution of Civil Engineers, Great George-street, of instruments, charts, maps, and photographs relating to climatology, and of such new instruments as have been invented since last exhibition.

Carmarthen.—A special meeting of the Carmarthen Town Council has been considering the question of public lighting. Gas is 4s. 6d. per 1,000, and the bill for the year comes to £450 for 191 lamps. The Council is intending to offer a lower price to the gas company. A little information on electric lighting might not come amiss to the Council.

Telegraphic Communication to Shetland.—At the last meeting of the Shetland Mails Committee, held at Lerwick, it was decided to petition the Post Office authorities to lay a cable connecting the outlying island of Fair Isle with the mainland; also to make arrangements for extending the telegraph to the island of Fetlar at as early a date as possible.

Aberdeen Public Library.—At a meeting of the subcommittee appointed in connection with the lighting of the Aberdeen Public Library it was decided, in view of the

fact that the building is to be lighted at an early date with electricity, that the gas fittings to be introduced should be of an inexpensive character, and such as would be suitable for adaptation to the requirements of the electric light.

Llanelly.—At a meeting of the Llanelly Local Board on Monday, a letter was read from the Llanelly Electric Light and Power Company with reference to the proposed electric lighting of the town, in which they asked the Board to name their terms for the handing over of the provisional order. A tender was also received from Messrs. J. D. F. Andrews and Co., but the matter was referred to a committee of the whole Board.

Coventry.—With reference to the deputation of the Coventry Town Council to the Crystal Palace, Mr. James, in the discussion as to its advisability, said he doubted whether it was needed as they had appointed a consulting electrical engineer, they had his advice, and this advice ought to be taken. He thought it unadvisable to reopen the question. The deputation, however, as already stated, was appointed, and will visit the Exhibition.

Whitehaven.—At the meeting of the Whitehaven Town and Harbour Trust, with reference to the electric lighting, the chairman said the surveyor had received a further tender from Messrs. Andrews. As that matter was referred by the Board to the Joint Harbour and Street Committee, he thought it would be convenient if a joint committee meeting could be summoned. This was agreed to. The meeting will take place on Tuesday.

Electric Travelling Crane.—The *Elektrotechnische Zeitschrift* for March 4 contains an article, with illustrations, of the new electric travelling crane built by the Allgemeine Company, of Berlin. It is mounted on a peculiar beam of L-shape, running on wheels, one rail being on the ground and the other near the roof of the warehouse. The crane is mounted on this beam in a covered house, and the motor winds up, slows, and also drives the travelling gear.

Tesla's Experiments.—The French papers this week are full of Mr. Tesla and his brilliant experiments. No man in our age has achieved such a universal scientific reputation in a single stride as this gifted young electrical engineer. The *Nineteenth Century* contains an article by Mr. J. E. H. Gordon, introducing the subject to the literary world in admirable and brilliant style reflecting both the scientific depth and the coruscations of the original experiments.

Taunton.—The question of the purchase of the electric works at Taunton caused a little scene at the last Town Council meeting. When the matter came up Alderman Standfast moved that the books of the company should be open to inspection, but several members left the Council-chamber, and one member declined to vote as he was a director of the company. So nothing could be done, Alderman Standfast exclaiming, "So that's their little game!"

Coast Communication.—Sir Michael Hicks-Beach, at the annual meeting of the Association of Chambers of Commerce, said that the Government would shortly state their views on the subject of telegraphic communication to light-houses and lightships, when Sir Edward Birkbeck's motion came before Parliament. Sir Edward Birkbeck stated that every member who had communicated with him was in favour of a Royal Commission. A motion to press the question was carried unanimously.

Colliery Lighting.—The Duke of Sutherland has accepted the tender of Mr. Joseph Blackburn, Gresham Works, Nottingham, for the supply and erection of engines, dynamos, and plant for lighting by electricity the Florence Collieries, and also a special arrangement by which the sinking of a new shaft can be carried on night and day. This shaft will be over half a mile in depth when completed. The whole work has been arranged and will be carried out from the designs of Mr. W. J. Furse.

Poisoning by Oxide of Copper.—An electrical workman recently was poisoned at Berlin in a very peculiar manner, which it will be well for electrical engineers to note. He had been used in testing his cells to find if current was flowing to put the two ends of his wires in his mouth, and the oxide of copper produced eventually caused his death. The galvanometer is now substituted in that workshop for this rough-and-ready test, which evidently is more dangerous than most persons would believe.

Blackpool.—The minutes of the Electric Lighting Committee, presented at the meeting of the Blackpool Town Council last week, stated that a draft report had been prepared, and that Mr. R. Hammond and Mr. Goode (Hammond and Co.) had had an interview with the committee on the subject of electric lighting. The Mayor, in moving the adoption of the minutes, said that inasmuch as their powers would very shortly expire, he hoped that the committee would push on their enquiries and lose no time in presenting a full and exhaustive report to the Council.

Teignmouth. — The Teignmouth Local Board on Monday considered the project which Mr. Reed, of Chagford, brought forward for lighting the town by electric light, at a cost of £12,500, on the low-tension system with accumulators. The chairman said he had received letters from Hammond and Co. and the Manchester Edison-Swan Company asking to be allowed to tender. It was stated that the extension of the gas work would cost £6,000. There is no water power near. Mr. Wheatley moved that the lighting of the town with electricity be deferred, and the motion was carried.

Southport.—At the monthly meeting of the Southport Town Council on Tuesday, the arrangements being made for the adoption of the electric light in the principal thoroughfares were brought up with reference to the Gas Committee's report. Alderman Hacking said they must avoid letting the supply remain in the hands of a company, who would make a profit of 10 per cent., for the Corporation could put the electric light into operation themselves by borrowing money at 3 per cent. He strongly advised the Corporation to undertake the manufacture of their own electric light. The minutes of the committee were confirmed.

Newington.—At the last meeting of the Newington Vestry the Works and Sanitary Committee recommended, and it was resolved: "That the Vestry offer no objection to the order lodged by the Camberwell and Islington Electric Light and Power Supply Company, Limited, to light this parish by electricity, subject (1) to the company consulting the vestry clerk and chairman of the Works Committee before purchasing or leasing a site in the parish for the purpose of a generating station, and (2) upon the compulsory area being extended from the Vestry Hall, Walworth-road, to the boundary of the parish in Camberwell-road.

Time Cut-outs for Motors.—Where arc lights or motors are ordered for supply during a certain period every day it is evidently to the advantage of the supply company to cut off the current at the exact time for which the contract is made. The Electric Secret Service Company have introduced a clock switch, which may find a useful field for this purpose. The clock is furnished with discs, notched in a suitable way on the periphery, which cuts the current in or out at the time stipulated. The discs can be made to act at various times and for various periods

every day. The apparatus is illustrated in the *Electrical World* for February 27.

Swindon is greatly occupied with the question of public lighting, and a large ratepayers' meeting has been held. Mr. A. D. Williams said there was no doubt whatever that the lighting of the future would be by electricity. He did not think it would be advisable for the Local Board to lay down a new gas plant or purchase the old one, as it was only a question of time before lighting by electricity became very general. The chairman remarked that the electric light would not supersede gas altogether, but it would tend to reduce the price of gas. The idea that electric light should be used, it seems, is rapidly growing.

Aluminium Manufacture in India.—Prof. Alfred Chatterton, B.Sc., of the Madras Engineering College, has a very suggestive paper in the *Indian Engineer* for February 6th upon the possibility of utilising the immense water power of India for the electric production of aluminium. Prof. Chatterton enters very fully into the practical details and financial aspect of the proposed scheme for the use of 125,000 h.p. He suggests the investment of £1,000,000, and shows figures, which, though rough, are, he maintains, under rather than overstated, resulting in a profit capable of returning 75 per cent., with aluminium at £200 a ton. Meanwhile it is suggested that a syndicate secure from Government the right to use the water power of the Periyar project.

Hobart Tramways.—The Hobart Tramway Company has been brought out this week with the capital of £105,000 (College-hill-chambers, Cannon-street), to establish three miles of electric tramways in Hobart, Tasmania, on the overhead conductor system. A contract has been made with Messrs. Siemens and Co. to equip the line with 20 cars and the electrical fittings and accessories for working the tramways, for the sum of £33,000, the work to be completed so that the line may be ready for opening for public traffic by the 1st of December, 1892. This firm has also agreed to work the line until the 31st December, 1893, at 4d. per car mile, receiving not less than £1,000 per month, including in same wages of conductors, drivers, and of all the necessary maintenance staff.

Glasgow Tramways.—The minutes of the Tramway Committee presented to the Glasgow Town Council last week contained the report of the sub-committee on mechanical haulage, and notes of their visit to Chester, Birmingham, London, and Leeds. Bailie Paton, in moving the adoption of the report, said the Electric Traction Company still held open their offer. Possibly the best information the deputation received was at Leeds, from the overhead conductor line, and they were extremely pleased and delighted with what they had seen. The three miles of track had cost £20,000, and had been laid down in less than six months. The present lease in Glasgow had two years yet to run, so that there was plenty of time to watch the development in Leeds before they made up their mind to adopt electric traction. The minutes were approved.

Bradford.—The minutes of the Bradford Gas and Electricity Supply Committee included a resolution advancing the salary of Mr. S. W. Baynes, manager of the electricity works, from £250 to £300 per annum. Objection was taken to this, unless it were possible at the same time to dispense with the services of the consulting engineer, Mr. Shoolbred. Alderman F. Priestman defended the action of the committee, contending that Mr. Baynes was a most valuable servant, and was entitled to be better remunerated now that the electric works were becoming profitable. As to Mr. Shoolbred, he protested against the attempts to injure that gentleman's professional position, which was similar to that of an architect, and for all the work he did he only received the small commission of 3 per cent. The proceedings were confirmed by a large majority.

Electric and Cable Railway Bills.—On the motion of Lord Balfour, last Friday the House of Lords concurred in the following resolution communicated by the Commons: "That a joint committee of Lords and Commons be appointed to consider the best method of dealing with the electric and cable railway schemes proposed to be sanctioned within the limits of the metropolis by Bills introduced, or to be introduced, in the present session, and to report their opinion as to whether underground railways worked by electricity or cable traction are calculated to afford sufficient accommodation for the present and probable future traffic; as to whether any, and which, of the schemes propose satisfactory lines of route; as to the terms and conditions under which the subsoil should be appropriated; whether any and, if any, what schemes should not be proceeded with during the present session."

Sims-Edison Lifeboat.—Mr. Edward Palliser, in a letter to the *Times* of Monday, states that Mr. Sims is preparing drawings for adapting the Sims-Edison electrical motor and propeller to lifeboats. The system will be the same as used in the Sims-Edison torpedo recently tested at Portsmouth. The propeller will be placed in the bow, to bite the water as soon as possible with 45 h.p. The cable coiled in the boat will be from three to four miles long. The boat would be provided with a search-light. The electric current would be generated from the shore station, which may be two miles from the starting point of the lifeboat. He adds that Mr. Edison is taking the greatest interest in this new departure. The proposal, we may remind our readers, has already been mentioned, and a trial will be witnessed with great interest. It remains to be seen how electric cables would behave when attached to a lifeboat in a storm.

City Lighting.—The solicitor to the Commissioners of Sewers at the meeting on Tuesday submitted his report, showing that the dates of the contracts for the electric lighting of the east and central districts had expired. The clerk read a letter from the City of London Company, saying the total length in these districts was 31,105 yards, of which 24,388 yards was laid, and at this rate the work would be finished in three weeks. The contract for the western district expires November 5, by which time it would be complete. The solicitor explained that £1,000 had been deposited as caution-money. Mr. Johnson strongly opposed the resolution of Mr. C. T. Harris to consider the whole question in committee, saying it would be most dangerous to interfere; it was impossible to do the work quicker, or the whole traffic in the City would be stopped. The Court refused to move the resolution.

High-Tension Experiments.—The days when 2,000 volts were considered dangerously high are fast disappearing into the limbo where the idea of the danger of 40lb. of steam has gone. Nothing under 50,000 volts will content experimenters of the present day. Messrs. Siemens have this potential going at the Crystal Palace Exhibition, and we are now in receipt of an invitation from the Old Students' Association to their next meeting at the Central Institution, this evening (Friday) at 8 p.m., when a paper will be read on "The Behaviour of Insulating Materials under the Action of High Potential Differences," by Messrs. H. B. and W. Fox Bourne, members, illustrated by experiments with a transformer giving about 50,000 volts. Members may invite friends. Considering the importance that the subject is assuming, the Old Students should

obtain a large attendance. It is rather a pity the notice was not issued a little sooner.

Rochdale.—The councillors of Rochdale have been roused to a sense of the necessity for action with reference to the electric light by reading of the action taken by the Salford Corporation. But it turns out that Rochdale has no powers as yet for the introduction of electric mains, while Salford has, and fears to lose them. Several companies, it appears, have given notice that they wish to introduce electric light into Rochdale, but have always been opposed. Alderman Petrie said the committee were not standing in the way of the light, and as soon as they felt there was sufficient desire in the town they would introduce it. Alderman Heape made a suggestion as to the commencement of an installation by using the water power on the sewage farm, where there was a disused cotton mill which would give 40 h.p. This might be used at the technical school, library, and Town Hall. This is to be brought before the Gas Committee. The Mayor, who has the electric light on his premises, said the trouble was that his gas bill was almost as large as before, so much more light being used.

Burnley.—At the monthly meeting of the Burnley Town Council last week, Alderman Lancaster, in seconding the Gas Committee's report, said they were making progress with the electric lighting, though not so rapidly as they desired. At the present moment they were very much pestered with people who wished to show them various systems for working the town with electricity. The proposal of their engineer (Mr. Parker) was to put down Lancashire steam boilers driving horizontal engines at high speed with rope driving on to the dynamo, thus differing from the schemes of many electrical engineers who advocated driving the dynamo direct on the same shaft. Mr. Parker proposed to use the high-tension three-wire system with transformers. The committee proposed to erect a station on the plot of land to the left of the proposed new aqueduct, which would be one of the most central sites that could be obtained. The Council passed the recommendations of the committee, amongst which was one directing application to be made to the Local Government Board for sanction to borrow £25,000 for electric lighting purposes.

Mansion House Lighting.—A private view of electric lighting at the Mansion House was held on Monday evening to meet the Lord Mayor and Lady Mayoress. The installation, which has been carried out by the Planet Electrical Engineering Company, consists of 825 lamps of 5, 8, 16, and 50 candle-power. These lamps have been fitted over the whole of the Mansion House, including the following principal rooms: Egyptian Hall, Venetian Room, Long Parlour, Saloon, State Drawing-room, Lady Mayoress's Boudoir, Justice-room, and Morning-room. The whole of the work has been carried out to the specification of Mr. W. H. Preece, F.R.S., and the wire has been run in such a manner that not more than 10 lamps are placed upon one circuit, and economical burning has been fully worked out by arranging that the lamps on all the cluster fittings are split up into two or more circuits, so that a few lights for general use may be turned on instead of the whole of the lamps. The general effect is extremely handsome. The Lord Mayor stated his satisfaction with the installation, and during the evening the Lady Mayoress was presented with an ebony and silver portable lamp as a memento.

Bradford Electric Cars.—A short length of tramway line in Bradford has been taken in hand by Mr. Holroyd Smith, who has equipped it with overhead conductors for electric traction, for the purpose of experiment, with the co-operation of the Bradford Corporation, who will supply the current from their central station. The line has now been completed, running from Foster-square, up Cheapside, to Manor-road and Manningham-lane. Experiments will be carried out this week, and the car, which has been built for the purpose, will be run on the existing lines leased by the Bradford Tramways Company, the directors of which have given every facility for the experiment. The car will run for a few weeks, and the public will be carried at the charge of 1d. Official inspection by Major-General Hutchinson takes place this week. The car will seat 18 persons inside and 18 outside, the roof being fitted with garden seats. Great interest is aroused in the town, especially with reference to the steep gradient at Cheapside, where there is also a sharp turn. Should the experiment prove satisfactory the installation may be made permanent, though probably, it is stated, a conduit system may be used.

Catalogue of Ship Machinery.—The very enterprising Newcastle company, Ernest Scott and Mountain, Limited, have issued a valuable catalogue of engines and auxiliary machinery for war and passenger ships, which will be of interest to all who have to do with this class of machinery contracts. Triple expansion inverted cylinder engines, fitted with automatic expansion gear, for 150lb. steam pressure, make a very efficient prime motor for electric light stations. Solidly constructed combined engines and dynamos of Admiralty pattern have been specially designed to conform with Admiralty requirements for use where space is limited. Another form of combined plant shown in the catalogue is a compound vertical engine and Tyne dynamo, of which many sets are in use. Another form consists of horizontal engine and Tyne dynamo on the same bed-plate for situations where head room is limited. The catalogue further contains illustrations and descriptions of feed, fire, and bilge pumps, air and circulating pumps, workshop engines and condensers, also various classes of forced draught fans suitable for warships, besides hydraulic pumps, and illustrations of the large class of gunmetal castings that their foundry is capable of producing.

Oxygen and Ether.—Prof. Dewar's beautiful experiments demonstrative that liquid oxygen is powerfully magnetic ought, we think, to lead to some important modifications of the theory of magnetic circuits as taught in the text-books. What a boon to students it would be if we could only get rid of the necessity for the conception of ether altogether, especially in the early stages, where a clear idea of the interactions of molecular force is requisite! Ordinarily, the student is led to believe that magnetism is some force resident in the molecular structure of the iron or steel, but that outside the iron or steel the magnetic effect is transmitted by the ether. Why not attribute this exterior action to the effect upon the molecules of the oxygen of the air itself? We shall then have a clear conception of the whole magnetic circuit acting partly through the iron and partly through the oxygen. Even with an exhausted bulb we are perfectly aware that millions of molecules are necessarily left, and with freer paths for activity than before. Would it not be preferable to conceive the magnetic effect as being transmitted by actual magnetic effect upon the oxygen molecules, rather than leave this function to an unknowable ether?

St. Pancras.—Mr. Andrew Sweet, chairman of the St. Pancras Electricity Committee, has addressed the following letter to the editor of the *Times*: "Sir,—Paragraphs have been sent to several newspapers and an impression already widely prevails that the Vestry of St. Pancras, having withdrawn their Parliamentary Bill, are tired of electric lighting, and have no intention of extending

it in the parish. This is entirely a mistake. The first object of promoting the Bill was to raise money from the public when a difficulty arose between the Vestry and the London County Council as to the period over which the repayment should extend. Since then the difficulty has been surmounted and the necessary money has been borrowed. The present necessity for the Bill, therefore, has gone. I may add that electric lighting in St. Pancras is an assured success, and the Electricity Committee are now taking the necessary steps to extend the public lighting, which was commenced in Tottenham Court-road and Euston-road, through Hampstead-road and Camden Town. Furthermore, every day during the last fortnight we have at least one new applicant for current, and this morning comes an application from one consumer for about 600 lights."

Underground Sub-Stations.—A letter was read before the Beckenham Local Board, on Monday, from the Crystal Palace and District Electric Light Supply Company, Limited, asking the Board's permission to construct an underground apparatus in Sydenham-terrace. The company's secretary and manager (Mr. George Offor) attended the Board meeting. The Works Committee recommended the Board to sanction the application subject to an agreement at a rent of £10 per annum, and that the Board's surveyor reported that it was possible to accede to the request. Mr. C. E. Baker said what the company proposed to do was to bring in electricity of 2,000 volts strength, which would be reduced before being used to 200 volts. The chamber in which it was proposed to store the electricity would be divided into two compartments, one of which would contain motor-dynamos and the other accumulators. The chamber would be entered by a 2ft. door, and would be 40ft. long by 20ft. wide. The chamber would only be visited once a day, and dynamos would be continually running. The Board, it was maintained, had no power to authorise the construction, as they had no authority further than the surface of the soil, and the chamber would be between the footpath and the highway. After some similar remarks from Mr. Grenside the application was referred to a committee.

Oxford.—At the monthly meeting of the Oxford City Council last week, the General Purposes Committee recommended the Council to appoint a standing committee, to be called the Electrical Committee, to deal with all matters relating to the introduction of electric lighting into the city, with power to obtain the assistance and advice of a practical electrical engineer. The following were appointed: The Mayor, the Sheriff, Aldermen the Provost of Queen's, Wilson, Deazeley, and Green; and Councillors Underhill, Morrell, Shadwell, Ogle, Kingerlee, Salter, Daniel, Rose, and Colonel Swinhoe. The Parliamentary Committee reported they had considered an application from Messrs. Walter Webb and Co., solicitors to the Electric Installation and Maintenance Company, Limited, as to their application to the Board of Trade to sanction a transfer to the Oxford Electric Lighting Company, Limited, of the provisional order, and recommended the Council to assent to the transfer. Alderman Deazeley said the committee thought that with the deposit of £1,500 the ratepayers were held safe in respect to damage to the streets, and they thought also, as the new company had precisely the same liabilities and responsibilities, there was no risk run. The committee further considered it was undesirable to discountenance local enterprise, and Mr. Offor who was manager of the Electric Installation Company, was also a very prominent member of the new company. After discussion, the report was adopted.

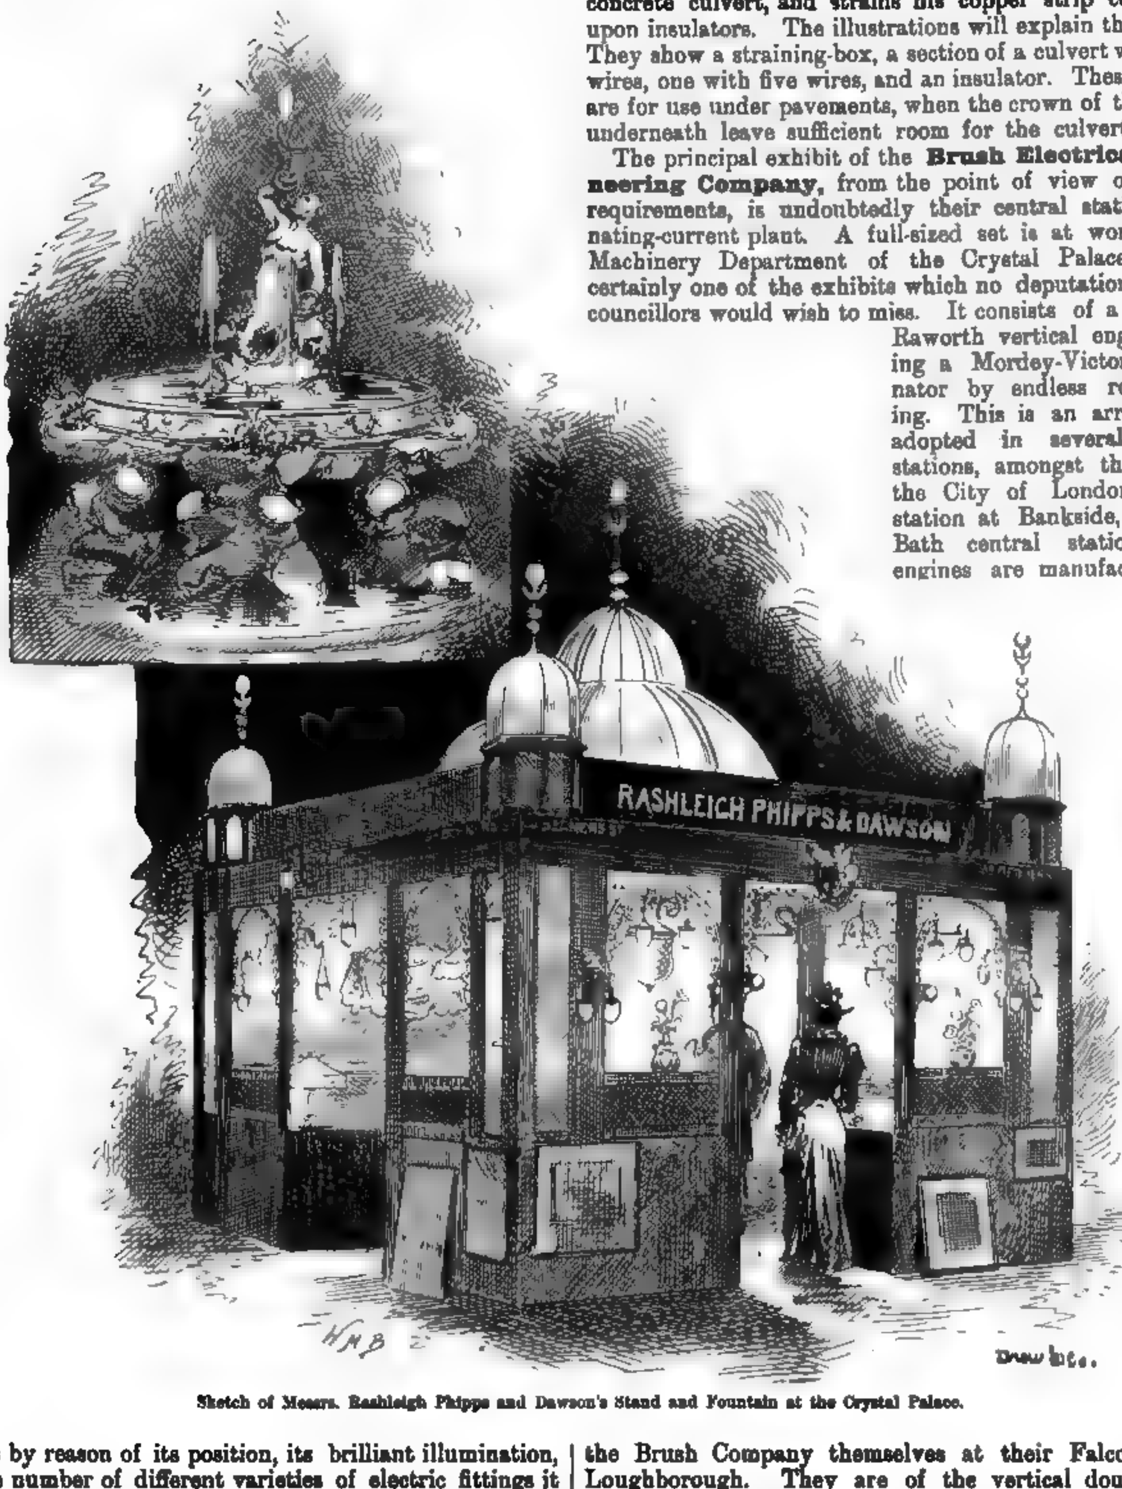
Liverpool.—The Liverpool Watch Committee, at their meeting on Monday, came to the decision to postpone the introduction of electric lighting for public streets. A report was presented by Mr. Boulnois, the city engineer, who had gone most carefully into the subject. After describing the action that had already been taken by the Council, and the results of the experiments that had been made, the engineer embodied in his report the information he had obtained from other towns where the electric light is now in use for public purposes. He presented plans of two areas, one including the whole of the central portion of the city, and the other an equally central but considerably smaller section. In the consideration of this subject two things had to be considered: first, the increase in the illuminating power, and, secondly, equal illumination at a reduced cost. The engineer explained the best mode of electric lighting now available, and compared it with the illumination of the streets by gas. In the larger area the cost annually would be £9,858, whereas the present cost of lighting the same is £3,863; but the estimated cost of the electric light includes the whole of the expenditure on the insulation, as well as interest on sinking fund and all initial charges. After discussion, a resolution was passed that the Watch Committee are of opinion that, having regard to the conditions of rapid development to which the system of electric lighting is now subject, it is not at present advisable to adopt the system. A copy of the city engineer's report is to be sent to each member of the Council.

Waterford.—A serious crisis threatens the electric lighting interest in Waterford, if we are to believe the *Waterford News*, which takes up the question very warmly in a leader, from which the following is taken: "We have heard it whispered that the Lighting Committee are recommending the acceptance of a tender from the gas company for the supply of the public lighting of the city at the rate of £2. 10s. per lamp, or just £1. 5s. less than was paid when this illuminant was in use before in our streets. This will entail the abolition of electric lighting in the city. The step is a very serious one, and we fear it has been resolved on without mature consideration. When the Corporation went to Parliament seeking a provisional order for the right to light the city by electricity, it was the general impression that immediate steps were to be taken to procure the plant, and have the lighting carried out under the control of the Council. In obtaining the provisional order close on £200 of the public money was expended. How can this expenditure be justified if, a fortnight after the granting of the looked-for order, a decision to revert to the worn-out system of lighting by gas is resolved upon? We are mystified. The public will want a very full explanation. At the present moment we see almost every city and town in the United Kingdom substituting electric light for gas. In London, Dublin, Belfast, Limerick, Londonderry, Newry, Kilkenny, and even in Carrick-on-Suir movements are afoot to adopt the more modern system of lighting. The electric light has been established by the local authorities in Carlow. In Dublin gas is but 3s. 6d. per 1,000ft., yet the Corporation have decided to do away with it for the lighting of the streets. We (Waterford) were the pioneers of electric light in Ireland. Are we now to be the first to go back to the customs of olden times? The question is one which the citizens have every right to insist shall not be decided in an offhand manner. There is no time," adds the *News*, "to be lost, for, if all we hear is true, the committee have their report cut and dry for the approval of the Corporation." The promoters and representatives of electric lighting will have to bestir themselves actively, and the complete rout of the gas interest in Larne recently should give them a powerful lever on their side.

THE CRYSTAL PALACE EXHIBITION.

Statistics are ofttimes hard convincers, and it may be so in the case of the numbers who have up to date visited the Exhibition. Compared with the corresponding period of the exhibition 10 years ago, we are told that to the end of last week the numbers were greatly in favour of the present year—that, in fact, 41,000 more visitors have gone to the Palace than at the previous exhibition.

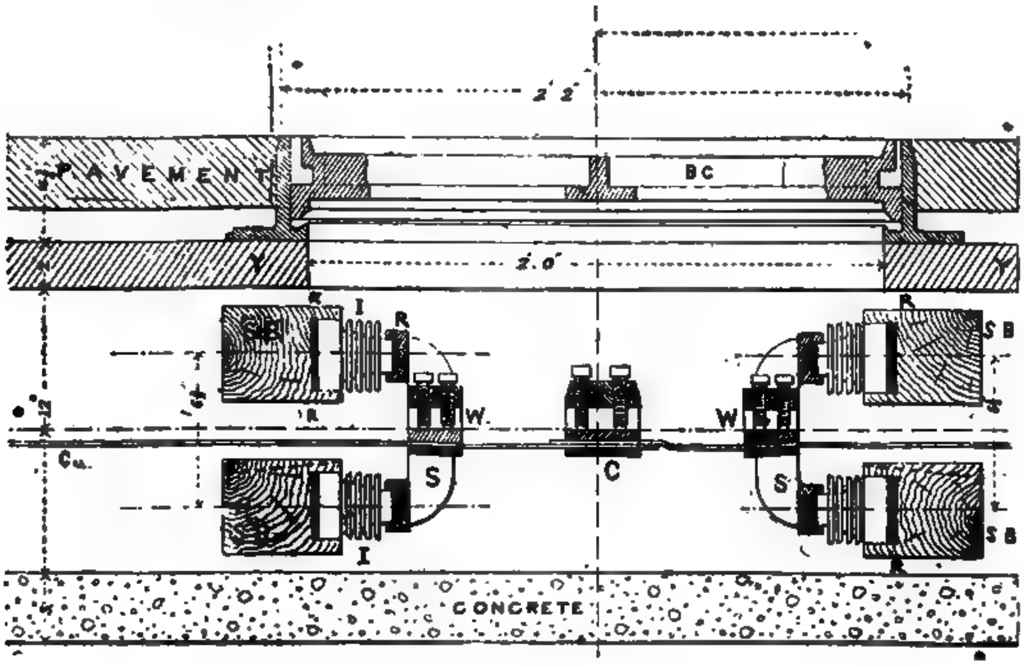
The central kiosk of **Messrs. Rashleigh Phipps and Dawson** attracts a large amount of attention from all visitors by reason of its position, its brilliant illumination, and the number of different varieties of electric fittings it contains. Some hundreds of lamps are lighted, and visitors are able to enter and inspect them at close quarters. The kiosk is always filled with admiring crowds, and the fountain in the centre, surmounted by a high-power lamp, gives a cool *al fresco* feeling to this noticeable exhibit.



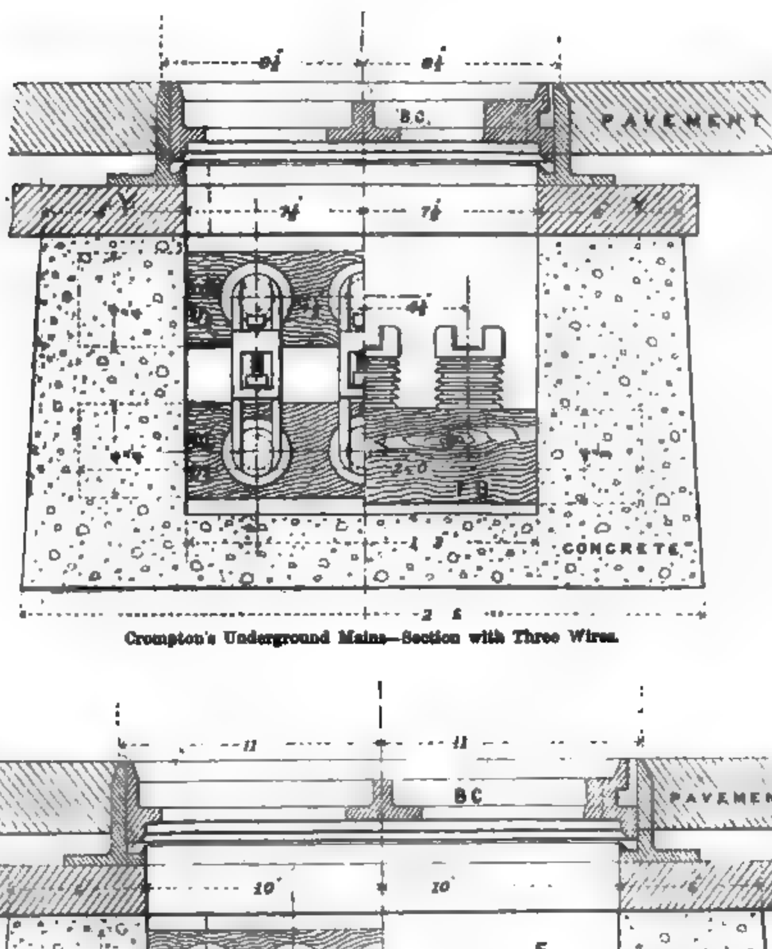
Sketch of Messrs. Rashleigh Phipps and Dawson's Stand and Fountain at the Crystal Palace.

The Machine Department may now be termed complete. We have arranged for a series of critical articles in each department—that is to say, on dynamos, on steam engines, on gas engines. Each set of articles will be contributed by an expert, and should, so to speak, determine the practice of to-day. Meanwhile, we may continue our ordinary description. Immediately on entering the Machine Department we come to **Messrs. Crompton and Co.'s** exhibit. For the sake of those who are not constant readers of this paper we may reproduce some of the illustrations of the Crompton system of mains, so fully described in vol. vii. The example shown at the Palace on one side shows three conductors; on the other side five conductors, representing the previous three-wire system and a pair of feeders. The Municipal Engineers, who visit the Palace to-morrow, will be well able to determine the value of the system as interfering with streets or pavements. Mr. Crompton makes a concrete culvert, and strains his copper strip conductors upon insulators. The illustrations will explain themselves. They show a straining-box, a section of a culvert with three wires, one with five wires, and an insulator. These culverts are for use under pavements, when the crown of the cellars underneath leave sufficient room for the culvert.

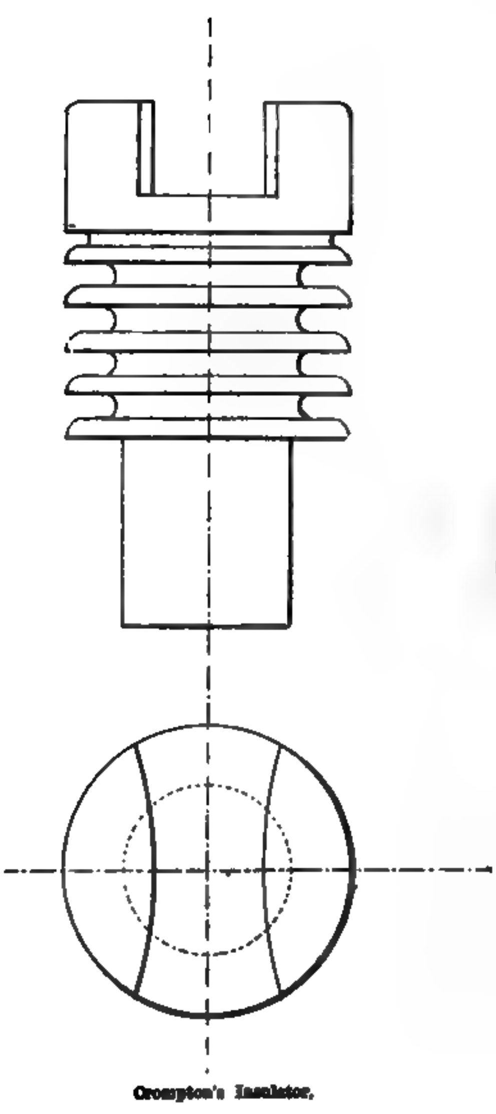
The principal exhibit of the **Brush Electrical Engineering Company**, from the point of view of present requirements, is undoubtedly their central station alternating-current plant. A full-sized set is at work in the Machinery Department of the Crystal Palace, and is certainly one of the exhibits which no deputation of town councillors would wish to miss. It consists of a 280-i.h.p. Raworth vertical engine, driving a Mordey-Victoria alternator by endless rope gearing. This is an arrangement adopted in several central stations, amongst them being the City of London central station at Bankside, and the Bath central station. The engines are manufactured by the Brush Company themselves at their Falcon Works Loughborough. They are of the vertical double-acting marine type, occupying the minimum of floor space, usually a matter of great importance in large towns. The speeds are sufficiently low to avoid undue wear and tear, while high enough to allow driving without countershafting. Special attention has been paid to the design of the lubricating arrangements, and these engines can be run continuously for days or weeks together if needed. A highly sensitive governor is provided, capable of adjustment to control within 2 per cent. It is furnished with two belts, so that the failure of one will not allow the engine to race.



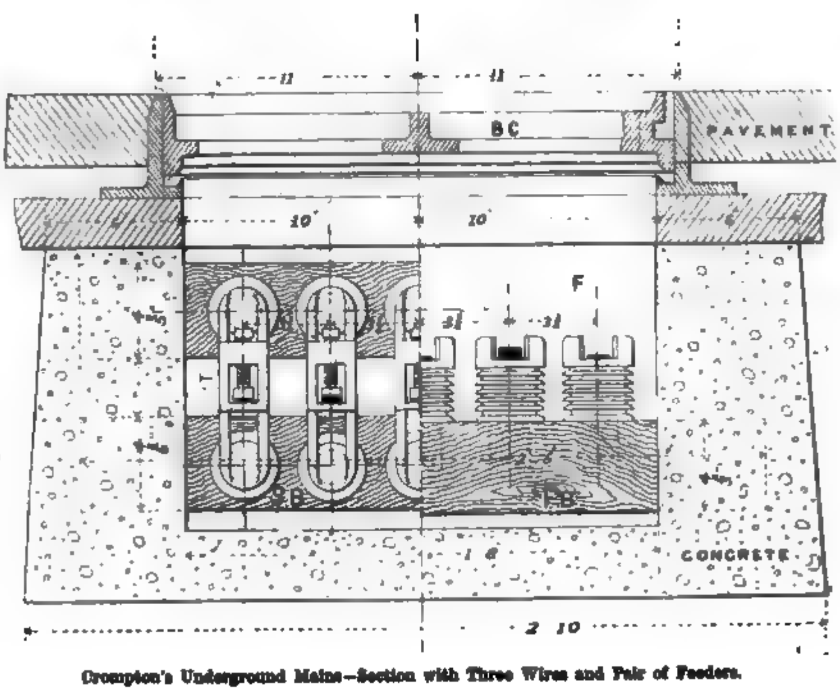
Crompton's Underground Mains—Straining Box.



Crompton's Underground Mains—Section with Three Wires.

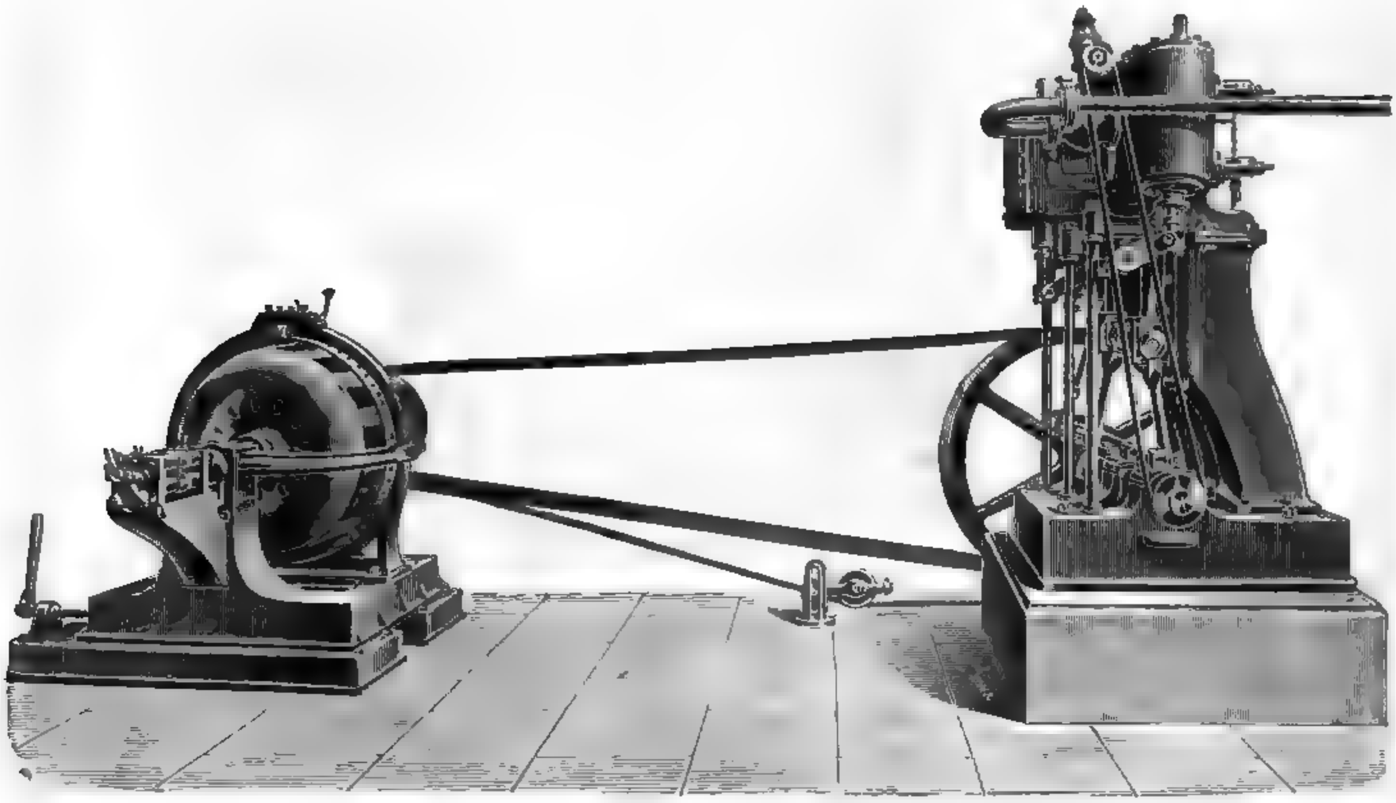


Crompton's Insulator.



Crompton's Underground Mains—Section with Three Wires and Pair of Feeders.

The Brush Company mostly employ endless rope gearing for driving their central station dynamos. A single cotton rope is passed usually eight times around the engine fly-wheel and the dynamo pulley, with what is termed a jockey pulley, suitably fixed for tightening, and to carry the cross-over rope. This arrangement is practically noiseless, and allows the use of shorter driving centres than is permissible with belting.



The Brush Company's Mordey-Victoria Alternator and Engine with Endless Rope Gearing.

The Brush Company's Combined Engine and Dynamo.

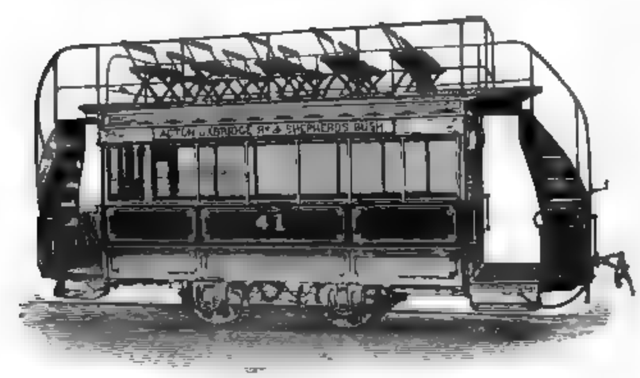
The alternator is of the well-known Mordey-Victoria type, which possesses several features distinct from other alternating-current machines. In the first place, it is very *reliable*, comprising fewer working parts than any other machine of this class. The armature is stationary, and is thoroughly insulated. It is so arranged as to be readily got at for repairs, and in the event of a coil giving way a new one can be inserted with the minimum of trouble. A further advantage is that no brushes or rubbing contacts are required, the mains being connected direct to two terminals. The field magnet is of a simple form, and has the advantage, if required, of only one large exciting coil, instead of a large number of separate coils. By revolving the field magnets instead of the more delicately constructed armature, safety in running is assured, while the weight of the field magnets act as a flywheel to keep

the speed steady. An important feature of this alternator is that although its highest efficiency is reached when fully loaded, yet it works very economically with light loads—a point of great weight in central station work. These dynamos work admirably in parallel, so that where, as in town lighting, the load varies continually, extra machines can be switched on with safety. This enables any circuit to be fed with one, two, or three dynamos, so that the machinery can be thrown in as desired, and in the event of one dynamo or engine having to be stopped, the others can continue without causing

The Brush Company's Transformer.

variation in the light. A unique feature of these machines is that the armature is entirely visible during running, and may be examined then or at any other time without the necessity for removing any portion of the machine. It is fully accessible for the purpose of cleaning or repairs without the removal of any part of the machine. The alternator shown is of 100,000 watts, capable of lighting about 4,000 8-c.p. lamps.

The standard switchboard used in the Brush alternating-current stations is simple and efficient. All the alternators



The Brush Company's Tramcar.

feed into a pair of "omnibus" bars or common conductors, and all circuits are supplied directly from these bars. Each alternator is provided with a standard switchboard, on which are all instruments and connections required, placed behind a locked glass door. The only exterior parts are the switch handles attached to gut bands passing through the lower casing. This prevents all possibility of accident, and renders the manipulation exceedingly simple. When a station is started, a standard board is provided for each existing dynamo and one for each circuit. As further machines are added an additional switchboard is inserted. In this way there is no necessity for providing specially designed switchboards. Future requirements, however extensive, fall naturally into the same system without difficulty or complication.

The Mordey-Victoria transformers used on the Brush system for reducing the high electric pressure generated at the station to a pressure suitable for the house supply, are of simple form. As with all transformers, they consist essentially of two windings of insulated conductor arranged with reference to a mass of iron, so that the high-pressure currents entering one coil induce low pressure currents in the second coil. The design aims at economy of construction, accessibility for repairs, thorough lamination, good ventilation, and high efficiency at all loads. For interior use the transformer is mounted in a simple manner without special protection. They can be placed on a shelf or on wall brackets out of reach. For exposed positions the transformer is made weather-proof, and mounted on iron castings, fitted internally with high-tension fuse and switch.

One of the exhibits which always attracts a large share of attention from technical and non-technical visitors alike is the row of Brush combined engines and dynamos, which, with "no visible means of support," are continually merrily working away as if in regular action. These are driven, there is perhaps no need to explain, by the dynamos working as motors; but the engines in running order, coupled to Victoria incandescent machines, make a striking show, and have, as we happen to know, resulted in many enquiries for this kind of plant.

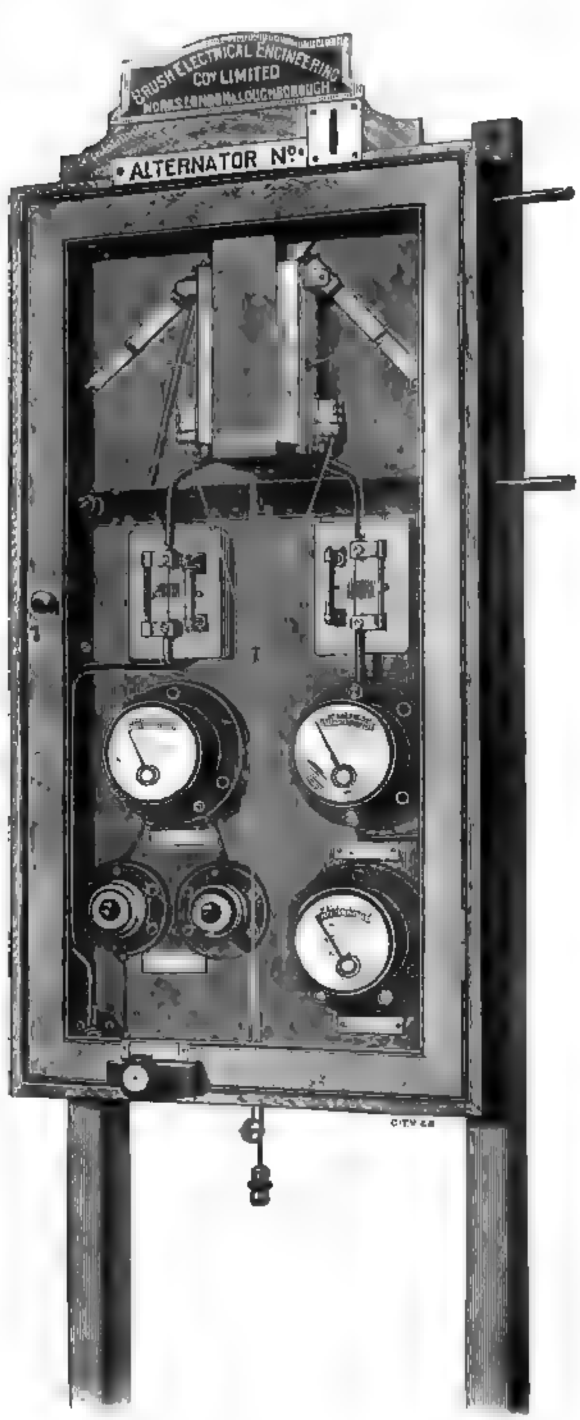
The beautifully-made tramcar, constructed by the Brush Company at their Falcon Works, makes also a splendid exhibit from the spectacular point of view, and illustrates the kind of car the company would provide when orders for electric tramcars are given to them.

THE RIES REGULATING LAMP SOCKET.

BY WILLIAM J. HAMMER.

One of the most interesting and ingenious appliances exhibited before the convention of the National Electric Light Association in America, at its Montreal meeting last summer, was a form of lamp socket devised by Mr. Elias E. Ries, of Baltimore, Md., U.S.A., for controlling individually the candle-power of incandescent lamps upon alternating circuits. In view of the widespread interest which this invention has attracted in America, and its great commercial value in electric lighting by alternating currents, and, furthermore, in view of the installation now being made at the Crystal Palace Electrical Exhibition of the first Ries

appliances shown on this side of the water, a few words upon the subject of controlling the candle-power of incandescent lamps in general, and particularly by this appliance, may prove of interest.



The Brush Company's Alternating Switchboard.

Many attempts have been made to produce a satisfactory and economical method of turning down incandescent lamps. The earliest experiments which were made by Mr. Edison and others, and in which carbon rods, plates, coils of German silver, platinium, iridium, and other metals were introduced in series with the lamp, thus causing considerable of the energy cut out of the lamp to be dissipated as heat, proved inefficient or of little commercial value.

Lamps were also constructed containing two or more carbons, which could be connected in series or multiple, to vary the candle-power, and a lamp invented by the writer many years ago contained a number of carbons of various candle-power, which could be separately introduced into the circuit to give any degree of light desired.

Inventors have also endeavoured to construct an economical device for controlling the light without the introduction of resistance, as the value of such a means of *regulating* the incandescent light has always been appreciated, and one of the principal claims of gas engineers is that the incandescent lamp could not be turned up and down, certainly not with the efficiency which existed in the gas system.

Mr. Philip Diehl, of Elizabeth, N.J., has presented the author with a complete set of the experimental steps in his alternating-current lamps, which show a very interesting stepping-stone in this direction. Before proceeding further let me say a few words upon the principle of the reaction coil which has been applied in various ways by Prof. E. Thomson, Shallenberger, Ries, and others, and referred to in the works of Fleming, Hopkinson, and others. A reaction coil of the most simple type is constructed of one coil of a conductor wound round a magnetisable core—probably the simplest form employed commercially is the ordinary spark coil used in electric gas lighting.

A direct current passed through such a coil magnetises the core and sets up lines of force which maintain the same direction so long as the current is continued; there is a slight heat also produced in the coil due to its ohmic resistance. Naturally, reversing the direction of the current reverses the polarity of the magnetised core. It does, however, more than this. This reversal of current, and consequent disturbance of the magnetic field, produces practically a transformer with but one coil, in which appears the impressed E.M.F. and the counter E.M.F. The counter E.M.F. retards the primary current through the coil, producing the "choking effect," as it is termed. In employing a continuous or direct current the counter E.M.F. is produced only at the instant of closing of the circuit or reversing the direction of the current, but with rapid alternating current the counter E.M.F. becomes as constant as the impressed E.M.F. of the primary current, and in the Ries socket the ratio of these may be varied, thus controlling the candle-power of each light independently and without resistance, and, as shown by Fleming and others, with an infinitesimal loss.

When the difference between the two E.M.F.'s is greatest, as determined by the position of the regulating key, the light is at its maximum, and when this difference is such that the two E.M.F.'s nearly approximate each other, the filament glows at its minimum point of light. One of these E.M.F.'s being variable with respect to the other, it will thus be seen that lamps of any desired voltage less than that of the supply circuit can be safely burned at their normal candle-power, and that standard lamps of any given voltage or resistance that are supplied with a normal E.M.F. of, say, 50 or 55 volts, can be burned at any degree of brilliancy required all the way from a barely perceptible glow up to their maximum candle-power. The most remarkable part of this method of electric lighting is its extremely high efficiency and the self-contained simplicity of the apparatus by which it is carried out. The writer has in his possession sockets of this character in which the two E.M.F's so nearly balance each other as to extinguish the light without even the necessity of opening the lamp circuit, the amount of energy consumed in maintaining this balance being so slight as to be measurable with only the most sensitive instrument. I have personally placed lamps in series with a sensitive ampere-meter, and varied the current from $3\frac{1}{2}$ amperes to $\frac{1}{10}$ of an ampere, as perfectly as gas is turned up and down, the ampere-meter indicating the variation in current precisely as if it were a fluid or gas which was being turned on or off.

The writer has had the privilege of witnessing some ingenious and beautiful effects produced by Mr. Ries, which show the facility with which this socket lends itself to modifications, adapting it to special requirements. For example, one is enabled to operate a 110-volt Edison lamp on a 55-volt Westinghouse alternating circuit, or to operate a 55-volt lamp on a 110-volt circuit, at the same time to produce all the variations in light from nothing up to full candle-power. All this, it should be noted, is produced with practically no loss of current, and entirely by the reaction of the current upon itself—no moving apparatus or outside connections whatever, other than the usual circuit adjustments on ordinary lamp sockets, being employed.

A very good idea of the general appearance of the Ries regulating socket, as at present made, may be obtained

from the accompanying illustration. The socket comprises an enclosing shell of neat design, and but slightly larger than the well-known types of "make and break" sockets now in use, and contains a small counter E.M.F. generator, or reaction coil, or choking coil, of peculiar construction, which, however, may be of any desired type so long as the general conditions to which it owes its high efficiency are adhered to. In the type of socket illustrated, this coil consists of a small, thoroughly laminated, closed iron core built up of numerous rings of specially prepared iron, the whole being compressed, taped, and wound at one operation with a special silk-insulated cable containing a number of separately insulated copper wires of different diameter, varying according to the maximum current to be carried by each, the ends of these wires, after the cable is wound, being connected in series with each other by contact-pins arranged in the path of an arm attached to the operating key. The interior connections are such that, when the socket is wired up, more or less of the wire composing the coil is in series with the lamp filament, according to the position of the operating key, and the length of wire thus included determines the amount of counter E.M.F. generated, or to express it in

The Ries Regulating Socket.

another way, by cutting out turns of the coil the self-induction is lessened, and more current is allowed to flow through the wire to the lamp. The light is divided by this socket into seven different stages, and the potential difference between each contact-pin being but one-seventh that of the total difference of potential on the mains, the flashing at these points is very slight, no snap action or other complicated make and break mechanism being employed. The entire arrangement is one of great simplicity and compactness, requiring no more attention and knowledge in operation than the turning on and off of an ordinary gas burner, which in this respect it closely resembles.

When the lamp is burning at full candle-power practically all of the coil sections are cut out—that is to say, when lamps of the normal voltage of the supply circuit are used. Usually, however, it is advisable to employ lamps of somewhat lower voltage, so that if for any reason the pressure on the circuit falls below its normal, the lamp may be turned up so as to still give its maximum candle-power, a feature not at present attainable with the ordinary type of sockets in general use. When the full amount of light is not needed, the counter E.M.F. generated is increased by the cutting in of additional coil sections, thereby reducing the flow of current through the lamps and causing the latter to glow at a lesser degree of brilliancy, and at the same time materially reducing the strain upon the lamp filament. The winding of the socket is so arranged that when the light is turned down to its lowest stage, the filament is just visible in the dark, so as to readily enable one to locate the position of the lamp upon entering the room and to turn it up to the desired point without having to first feel around for it among the electroliers or other fixtures of which it forms a part. By the use of this socket one may have some lights in a room burning at low brilliancy and others at a lower degree of incandescence, thus distributing the light exactly where it may be wanted, instead of being compelled to burn the lamps full on when little light is needed. The direct effect of this method of regulation is that, with a given expenditure for current, the average number of lamps in use may be largely increased, and the fact that it is thus possible to burn the lamps at a lower glow, and consequently at a reduced average cost for current and lamp renewals, especially in rooms, hallways, and other places that may be partially or entirely unoccupied for hours at a time, will lead to a very much more extended use of the incandescent electric light than it has hitherto enjoyed, and at the same time open up to electric lighting stations a great deal of new and profitable territory which is now beyond their reach. The saving in current that this socket is capable of effecting is almost beyond the belief of one who has not tried it, and actually surpasses everything that has yet been claimed for it in this direction. The writer has had occasion to thoroughly investigate this point recently, and has found that a 25-c.p. 50-volt lamp which consumed 75 watts when burning in one of these sockets at full candle-power consumed, together with the socket, just three watts, or only $\frac{1}{25}$th of the total energy, when burning at a low degree of incandescence equal to that produced by a net potential difference of 10 volts at the lamp terminals. This means that it is possible to burn 25 lamps at a visible degree of incandescence by means of this socket with the same amount of electrical energy that a single lamp would consume burning at its normal candle-power. Of course, the light given by the lamp at this point, while sufficient to render the filament of the lamp visible at a distance, was altogether too small for the purpose of affording outside illumination, and therefore this cannot be taken as a criterion of the average consumption of current in practice, which would be very much higher, especially as the lamps are usually burned at nearly full candle-power by the consumer when in actual service for furnishing light, the intermediate stages being used, for the most part, only for all-night service in sleeping apartments and other places where under the existing condition of things the incandescent light, if used at all, would be turned off altogether.

In conclusion, I would call attention to the fact that while the sockets shown at the Crystal Palace are only slightly larger than an ordinary Edison socket, they may be made considerably smaller where the rate of alternation is increased.

Douglas (Isle of Man).—Tenders are required for maintaining an electric light installation at Falcon Cliff Grounds, Douglas, Isle of Man. Full details can be obtained from Mr. Rowe, secretary, Cliff Company, Douglas.

Accumulator Tests. — Prof. Henri Dufour, of Lausanne, has been making tests with a number of storage cells with perforated plates. He gives the following results of his tests with reference to the ratio of capacity with weight: Huber accumulator (manufactured at Marby, Switzerland), 14·6 amperes per kilogramme (2·2lb.); E.P.S., 7 amperes per kilogramme; Reckenzaun, 7·2 amperes per kilogramme; Farbaky et Schenk, 11·2 amperes per kilogramme.

THE

ELECTRICAL ENGINEER.

Published every Friday.

Price Threepence; Post Free, Threepence Halfpenny.

Editorial and Publishing Offices:

139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

CONTENTS.

TO CORRESPONDENTS.

 Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 month
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d	17s. 4d
Other Places	4s. 10d.	9s. 8d.	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "THE ELECTRICAL ENGINEER" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

EDISON.

Advices are gradually reaching us that in the financial games as played across the Atlantic, Edison has met with a reverse. The wire-pullers of the Thomson-Houston interests, according to all accounts yet received, have scored a decided and probably a decisive success. The result is attributed to enemies at home. Trusted friends and comrades of Edison, it is hinted, have played their own hand and left the master's interests to the care of nobody. It has been our misfortune on more than one occasion to sharply criticise actions, financial and otherwise, taken, or said to be taken, on behalf of Edison; but we never expected to have to record his detriment through a trusted comrade. From first to last, so far as our history of Edison and his financial work goes, we have invariably found him putting his assistants into positions wherein they might make money. Not one or two, but numbers, have been able by their connection with him to rise from poverty to affluence. We have heard similar things said of Colonel North—that he never forgets his friends. Similarly Edison. If the interests of Edison have suffered because of the mismanagement of one or more of his trusted colleagues, it is a matter, in its personal aspect, to be deeply regretted. No doubt, boom upon boom has hitherto been consummated by a dexterous use of his name. The public have parted with large sums of money that have gone into the pockets of the schemers. From this point of view a possible good may arise. The public will be less prone to follow the calls of the charmers than when the position seemed unassailable. Edison has done good work, not altogether in the direction in which he is publicly accredited—so have other people; and this reverse will enable a more correct estimate to be formed of the true value of his work than has been previously possible. So far as we can gather, Edison has not believed in very high pressures. The systems he has devised have been with low pressures, and it must never be forgotten that he started from the earliest period of his lighting work with the view of designing a complete system of distribution. He studied carefully each link in his scheme, and though it was at first admittedly imperfect, it was a complete system. Without entering into any question of Swan *v.* Edison, we may be allowed to quote a sentence embodying the view above mentioned—a sentence written many years ago by one interested in Edison: "But it must be remembered that even if Mr. Swan's patents were for a lamp . . . his patents would still amount to nothing unless he had also invented and patented a comprehensive system of using them." We presume Mr. Lane Fox is at present fighting to show he designed a system in 1878; but this case being still undecided we must refrain from any comment. We trust, however, that it is not contempt of court to point out that Edison, and Edison only, proceeded at once to carry out his system upon a large commercial scale. Other inventors designed machines, or lamps, or cut-outs, or switches, but no one at that time troubled about a "complete

system." Although Edison may in this game of finance have met with a reverse, it is not to be considered for a moment that he will fail to hold a leading position in America as he hitherto has done.

THE CHATHAM ACCIDENT.

One of the most astonishing, although at the same time one of the most deplorable, accidents that have occurred in the history of electric lighting, is that recorded during the past week as having happened at Chatham. That a man, however ignorant, should have the temerity to meddle with an electric light circuit while the current is on is hardly conceivable. It is just as if a man thrust a burning brand into a gunpowder barrel and expected no harmful effects to follow, though perhaps most would place it on a par with seeking for a gas escape with a lighted candle. It is foolhardiness of this kind that brings discredit upon any industry, for there is no protecting the man who wilfully puts himself into a dangerous position. Still, this accident will have one good effect. It will cause engineers to ask if yet further precautions are not possible to prevent any man tampering with a dangerous wire in a house—in other words, is it necessary to have a wire carrying current under a dangerous pressure in the house at all? We are not going to specially discuss the Chatham case, but to take a wider view. That danger must exist at some point to meddling hands is true in almost every industry, and precautions are taken against hands meddling. Machinery is guarded, and henceforth high-pressure terminals, mains, or wires must be guarded. In series arc lighting wires are usually out of reach, but even in these cases notices may be conspicuously posted, cautioning anyone against touching wires while the current is on. In low-pressure work the present precautions seem ample, while in high-pressure work this accident points to the modification urged by many eminent engineers—no transformers in the house. If under no circumstance a current over a hundred volts pressure be brought into a house, it is difficult to imagine where danger can come in. Even in the transformer station there ought to be little difficulty in guarding the primary terminals and circuit from anything but wilful contact. At the present time a large number of switches ordinarily used are condemnably bad, and liable to lead to accident. Hardly any householder has a perfectly safe means of cutting off the main circuit, presuming the transformer in the house. A lambent blue flame playing across the contact would frighten everybody away from the switch, and no other way is provided for breaking the circuit. The handle of a switch, instead of being three inches away from the arc, might for the matter of that be thirty feet away, and the most timid would not mind turning the handle at that safe distance, although they would have too much respect for their fingers to touch the ordinary short handle. This is not a suggestion—it would be ludicrous to insist upon thirty feet of handle—but what must be insisted upon is the necessity of providing some method of breaking the main circuit that shall be absolutely safe under all circumstances.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

CRYSTAL PALACE EXHIBITION.

SIR,—Were you ever electrified? When next you go to the Electrical Exhibition at the Crystal Palace you should be. A few days ago a friend (?) persuaded me to get into that awful chair, and as soon as the thing began to go the sparks flew, and I was tortured with a metal brush and a stick of charcoal until the hair of my head stood on end "like the quills upon the back of the fretful porcupine." Oh, sir, if ever I——. Well, you try it, and if you survive you will probably feel as lively as the great American baboon of Rangoon that fell out of a palm tree on to the head of Sir Isaac Newton. Hence the discovery of greased lightning.—Yours, etc., X.

A DESCRIPTION AND COMPARISON OF THE METHODS OF ELECTRIC LIGHTING AT PRESENT IN USE IN LONDON.*

BY ALEXANDER B. W. KENNEDY, F.R.S., M.I.C.E., ETC.

(Concluded from page 231.)

Fig. 5 shows the arrangement of mains which I have adopted in my own district. It may be rather called a double two-wire than a three-wire system, and has enabled me to make a very great saving in copper, as compared with the ordinary three-wire distribution.

The Chelsea system, to which I have alluded, is one which General Webber has again lately described in detail before the Institution of Electrical Engineers, and which possesses much special interest. A single central station distributes continuous currents, at a pressure of from 500 to 1,500 volts, to a number of battery stations scattered through the district. The current does not go direct to the consumers at all, but goes entirely to charge accumulators. The pressure is maintained by charging the cells in series, either in one station or in several simultaneously. After being thus charged, the cells are discharged in parallel, so that each set gives a discharging current of about 100 volts pressure. The batteries are so arranged that one part is always delivering the current to the circuit, while the other is being charged, until the charge is complete. The leading advantage of this system, a very great one, is that the load on the engines is more or less independent of the fluctuation of customers' demands, and is therefore steady and fairly heavy while it lasts, so that the engines can work with considerable economy. The drawback is, that the whole of the current has to pass through batteries, which means, at the very least, a loss of 15 per cent., and probably more nearly 25 per cent. in energy, besides all the other losses in the mains, etc. Time only can show on what side the balance of advantage lies.

In order to supplement the batteries at times of the heaviest loads in winter, when in London day is turned into continuous night, and when therefore the charging can hardly overtake the discharging of the cells, the use of what are called continuous-current transformers has been commenced. A continuous-current transformer is simply a combination of a motor and a dynamo, so arranged that the motor part can be driven by a current of 500 volts pressure while the dynamo part gives out, like the batteries, a current of 100 volts pressure. This apparatus is an exceedingly interesting development in electrical engineering of which we are certain to hear more.

In conclusion, you will perhaps like me to say a few words about the cost of electric lighting in houses and

* Reprinted from the *Transactions* of the Royal Scottish Society of Arts, vol. xiii., part 1. Read May 11, 1891.

streets, as this is a matter which may very soon affect you closely in Edinburgh. Street lighting is a matter I have not mentioned yet, because there is as yet none in London, although the City itself is shortly to be lighted by a recently formed company. About public lighting the point to be remembered is, that in the streets people are not content with electricity unless it gives them 20 to 25 times as much light as they are getting from gas. Under these conditions it will cost at least four or five times as much as gas, and quite probably more. Light for light it will not cost more than about a quarter the cost of gas, and in any given case a community has simply to make up its mind whether it is worth its while to pay extra, although at a cheaper rate, for a very much better commodity.

As to private lighting, however, the figures are very different. Here the cost depends to a very great extent upon the amount of common sense which has been used in the wiring and lighting of the rooms and the amount of care which the householder is willing to exercise. If each light in a room has a separate switch, so that lights can be added as required, one at a time—if the lights are not covered up tate an expenditure of double or treble the current at an exactly corresponding increase of cost.

I try to put this very clearly in order that there may be no disappointment later on—at least, so far as I can obviate it—with the bills which will come in from your electric lighting company. Let me emphasise one point still more. If the electric light had to be left on in unused rooms as gas is left on, its cost would be twice as much as that of gas. It can only be brought down to the figure I have named by adopting rigidly the plan of turning it out always on leaving the room. With electricity this is so small a matter that practically it is no trouble whatever.

As to hotel and club lighting, where the same economy cannot be practised, and where, above all, the proportionate number of lights on at one time is always much greater than in a private house, the cost of electric light, even with all the economy possible, will hardly be less than double that of gas at 3s., supposing the electric light to be charged at the rate of 8d. per unit.

For shop lighting no figure can well be given, for the simple reason that the owners of shops generally use the light partly as an advertisement or attraction, and therefore

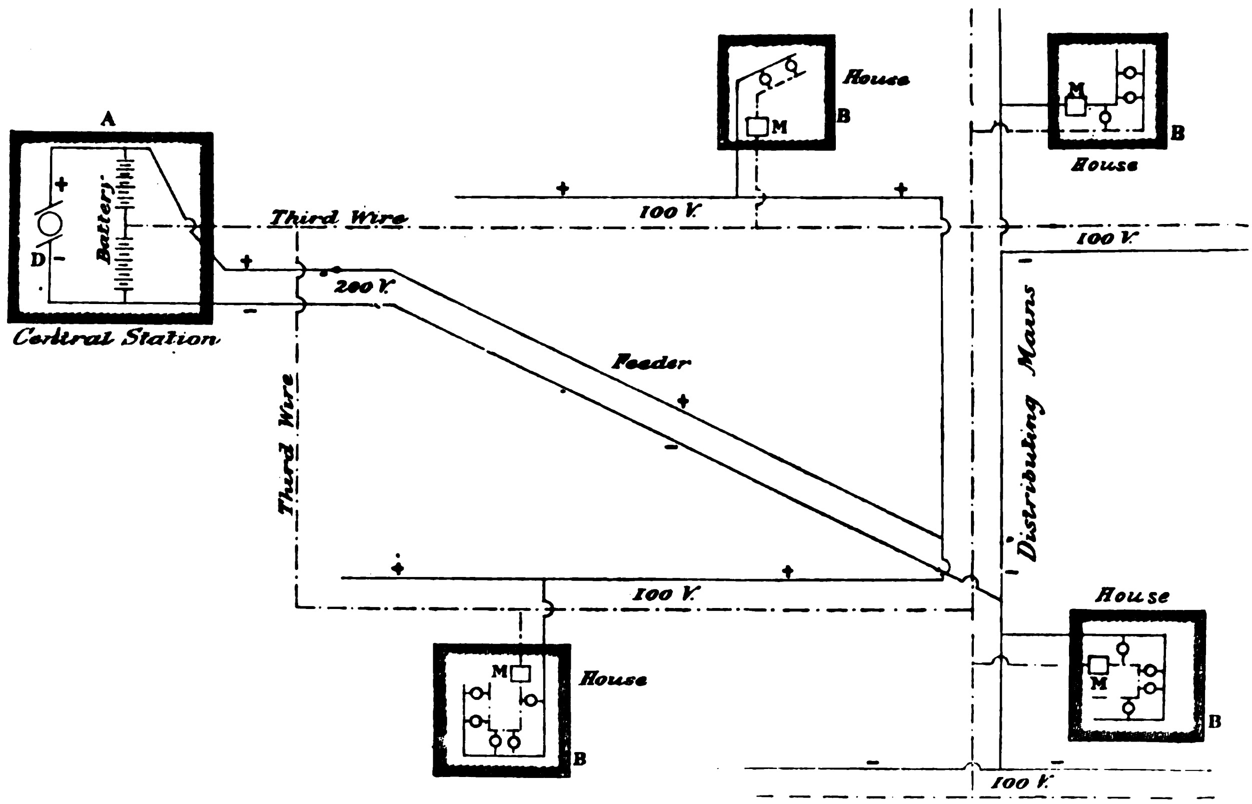


FIG. 5.

and darkened with frosted or iced or opal shades or glasses, which may be pretty, but which certainly absorb from 40 to 70 per cent. of the light; if people are content to replace 5-c.p. gas burners with 8-c.p. lamps, and do not insist on 16's; if every room has one switch placed just inside its door so that it can be turned directly the door is opened, then the cost of lighting a private house with electricity will probably be about 25 per cent. in excess of gas, if gas is 3s. per 1,000 cubic feet, and electricity 8d. per unit. Here, where I am told that gas costs 4s. 6d. per 1,000 cubic feet, there is no doubt that a private house can easily be lighted well with electricity at a less cost than with gas.

But it must be clearly understood that this estimate of cost does not apply if the house is so wired that two or three lights have often to be turned on when only one is required, or if the switches are so placed that it is inconvenient to get at them in the dark, so that the light is left on when the room is empty instead of being always turned out; or, worst of all, if the house mistress think "the little wire in the lamp," as she calls it, a detestable object, and insists on disguising it by ornaments, which absorb the greater part of the light generated, and therefore necessi- use very much more than there is the least occasion to use, finding no doubt, as they are the sole judges of what is good for their business, that it pays them to do so.

Actually the cost of electric lighting is known with great exactness to be a farthing per hour for an eight-candle lamp, and a halfpenny per hour for a 16-candle lamp, when the charge for current is 8d. per unit. On this basis any one can make out beforehand the exact cost of burning any number of lamps for any known number of hours.

My remarks have already extended to such a great length that I will not say anything about the light from the points of view of health, comfort, cleanness, coolness, and general convenience. No one who has ever tried it has ever expressed the least doubt on these matters, and they have for long been practically beyond question.

I can only conclude by expressing the hope that here in Edinburgh you may soon be able to verify for yourselves the universal opinion of those who use the light, and I shall be exceedingly glad if my remarks this evening have any influence whatever in helping forward the movement in which I understand your Town Council is already taking the first steps for supplying the city of Edinburgh with the electric light.

AN INTRODUCTION TO QUALITATIVE CHEMICAL ANALYSIS.

BY BARKER NORTH, ASSOC.R.C.SC. (LOND.),
Joint Author of "Introductory Lessons" and "Hand-book of Quantitative Analysis."

(Continued from page 162.)

Microcosmic Salt Beads.

A bead of fused microcosmic salt reacts in a similar manner to borax when heated with a few metals, and is therefore of great value in obtaining a knowledge of the composition of a substance.

How to Make a Microcosmic Bead.

This is done in the same way as in making a borax bead, but as microcosmic salt froths up a good deal on heating, a very small portion must be taken up at a time till the clear bead is of the proper size and quite free from bubbles. It is much more difficult to keep a bead of microcosmic salt on the loop of wire than one of borax, and if it gives any sign of falling off it may often be retained by turning the wire round slowly and continuously, or by holding the bead in the upper part of the flame in use.

Reactions Observed: Colour of Beads.

The reactions to be observed are similar to those of borax, the colour varying with the flame employed, and also depending on the heat of the bead, whether hot or cold.

Experiment 14.—Heat a salt of copper in a microcosmic bead made as above described, and notice that in the oxidising flame the bead is green whilst hot, and blue to green when cold, but that in the reducing flame it is dark green when hot, and an opaque red after cooling.

Sample Beads.

The student might with advantage make a set of borax and microcosmic beads from the following tables, and preserve them in a bent piece of tubing sealed up at the ends, as in Fig. 5. The microcosmic beads may be put in one limb and borax in the other, a mark being made on the glass to distinguish them. Two specimens of each metal should be kept, one made in the oxidising and the other in the reducing flame, and by taking account of the order in which they have been placed in the tube, they may be used for the recognition of another bead by comparison.

Table of Colours obtained in Borax Beads.

Nickel	Red to brown	Yellow to orange	—	Colourless

Flame Colourations.

When salts of certain metals are held on a piece of clean platinum wire in the outer edge of the Bunsen flame, very distinctive colourations are imparted to it, which may be used for recognising the presence of these metals.

Mounting Platinum Wire Used for Flame Tests.

The end of a piece of thin glass rod or tubing is softened in the blow-pipe, and while still melted the end of a thin piece of platinum wire, about 4in. long, is inserted, the two being afterwards fused well together and allowed to cool. In order to keep the wire clean it may be suspended in hydrochloric acid in a test-tube, by means of a cork through which the glass rod is made to pass, as in Fig. 6.

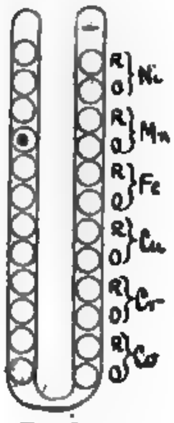

Fig. 5.

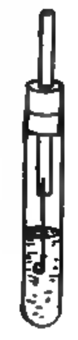

Fig. 6.

The wire should be well cleaned in acid before using, and no colouration must be observed when it is held in the outer edge of the flame, otherwise it is not clean. It is best, too, to take only a very small portion of the substance on the wire at a time, as certain metals, such as copper, antimony, lead, etc., act detrimentally on platinum, and great care should therefore be taken if these have been indicated by the blow pipe reactions.

Experiment 15.—Moisten the platinum wire with hydrochloric acid before dipping it in a sodium salt, and hold it in the outer edge of a Bunsen flame; observe the golden yellow colour imparted to the flame, and also that the light emitted causes the skin of the hand to look quite livid.

Experiment 16.—Now take a little of a potassium salt on the clean wire, and observe the violet colouration communicated to the non-luminous flame of a Bunsen burner.

Experiment 17.—Mix equal quantities of sodium and potassium chlorides and test on the wire as before; the potassium will be quite hidden by the sodium. If, however, a piece of blue glass be taken of such a tint and thickness as to render the strong sodium light invisible, and the flame from the mixed chloride be viewed through it, then the yellow rays from the sodium flame will be absorbed, and only the violet colour due to the potassium will be observed. The blue glass should be carefully tested with a pure golden yellow light from a pure sodium salt to make sure that all the rays from this flame are absorbed.

Experiment 18.—Another way to observe potassium in the presence of much sodium is to bring a little of the substance on the end of a platinum wire moistened with hydrochloric acid very gradually near to a Bunsen flame. The potassium salts being much more volatile than the sodium salts will be vapourised before the substance quite enters the flame, and the violet colour due to potassium will therefore be observed first, the sodium flame afterwards coming out strongly when the substance is brought nearer or into the flame.

Wet Reactions.

When the dry reactions have been carefully gone through, the substance is analysed in the wet way, and as this is the more reliable method, it will be a considerable advantage for the student to acquire manipulative skill in the working out of the reactions and processes of this method before treating of the independent reactions of the various metals.

In analysing a compound in the wet way, we first prepare a solution of the substance under examination, and then by adding other compounds in solution of known composition we observe the effect produced, such as change of colour, formation of a precipitate, etc. In the majority of tests which are applied in the wet way, the result observed will be the production of a precipitate which is simply an

insoluble compound formed by the reaction between the reagent and the substance under examination. In this way, by obtaining from various reagents different coloured precipitates which also have different properties, we are led to infer the presence or absence of any metal.

SOLUTION.

This is the first process to be performed in applying the wet reactions to any substance. We find that many substances, when mixed with water in the solid state, gradually disappear, or as we say dissolve, forming a solution of that substance in water. The liquids which thus cause substances to disappear, or dissolve, are called *solvents*. This is what is known as *simple solution*, as the substance can be again obtained unaltered by evaporating off the solvent. Other liquids, however, besides water may act as solvents; thus alcohol, in many cases, is also a *simple solvent*, and acids, such as hydrochloric acid, may also dissolve certain substances. As a rule, when acids are used as solvents, we no longer obtain simple solution but *chemical solution*, as, in the act of dissolving, a chemical reaction takes place, and, instead of the original substance going into solution, a new compound is formed which is soluble in water. Chemical solution is only used in ordinary analytical chemistry when simple solution in water fails to dissolve the substance.

In some cases it will be found that the compound to be tested is unattacked even by acids, and we may thus fail to dissolve it either by simple or chemical solution; such a substance is called an *insoluble*, and in these cases a different mode of attack has to be adopted.

Experiment 19.—Take a few crystals of lead nitrate and cover with water in a boiling-tube, the latter being simply a large test-tube. Show, by gently warming or by allowing to stand some time in the cold, that this substance disappears, or is dissolved. When a liquid is boiled in a test-tube, the latter will often become too hot to be held in the fingers, and a test-tube holder may be extemporised by doubling up stout paper into a narrow strip and holding it by the ends wrapped tightly round the top of the test-tube.

Experiment 20.—Now put a little carbonate of lime or chalk into water, and show that by warming, or even boiling, the substance remains undissolved. Notice, however, that directly a little hydrochloric acid is added that an effervescence commences, and proceeds till the solution is quite clear and the chalk all dissolved. The substance in solution is no longer chalk but chloride of lime, soluble in water, which has been formed by the chemical action of the hydrochloric acid on the chalk.

Experiment 21.—Show that barium sulphate is insoluble in not only water, but in dilute and strong acids, such as hydrochloric and nitric.

(To be continued.)

ANDREWS' CONCENTRIC WIRING.

Messrs. J. D. F. Andrews and Co. have recently completed an installation at the Tyne Theatre, Newcastle-on-Tyne, for Sir Augustus Harris, the wiring being done on their concentric wire system. Our readers have long been acquainted with this system, and visitors to the Palace Exhibition will be able to fully examine the system for themselves.

In the Tyne Theatre installation the concentric principle is adhered to throughout, extending to the switches, fuses, fittings, etc., and in these, as in the wiring, we note the close attention which has been given to mechanical as well as electrical perfection. Incandescent lamps are used, and include six 200 c.p., 12 50 c.p., and about 180 8-c.p. lamps, all of which are on the stage. The former supersede the limelight for the floats, and, from facility of control and absence of hissing, are a decided improvement. The remaining lamps are used to illuminate festoons, statuary, etc., and the artistic manner in which they are arranged has a most pleasing effect.

The current is conveyed from the leads by means of Andrews' patent concentric flexibles. The fact of all fittings having to be connected and disconnected in a few minutes, owing to changing of scenes, and the consequent rough usage to which they are subject, is conclusive proof of their adaptability and mechanical perfection. The ease of manipulation of this system is obvious when we state that the electric lighting used in the garden scene of the present pantomime comprises nearly 200 lamps; and at the close of the scene the whole of these, as also the flexibles, are disconnected and stored away by two men in the short space of three minutes. At some points in the pantomime all the lamps have to be switched on and off. The current is derived from the mains of the Newcastle and District Electric Supply Company, of which Mr. W. O. Hunter is the manager.

The installation, which from its substantial and finished nature reflects credit on all concerned, has been carried out by Messrs. J. D. F. Andrews and Co.

Electric Lighting at the Tyne Theatre—Andrews' Concentric Wiring.

EDISON AND THOMSON-HOUSTON.

THE PROPOSED AMALGAMATION.

Thomas A. Edison, the "Wizard," the king of practical electricians, has been "done." The hands of Wall-street manipulators are seen everywhere in the act of his undoing.

The calm, clear-headed, big-hearted inventor relied on friends and business associates. The former were speculators; the latter have largely proved incompetent. The result of the intellectual giant's dependence will be the amalgamation of the Edison General Electric and the Thomson-Houston Companies. The reorganisation plan was practically agreed on several days ago. Henry Villard arranged it. Drexel, Morgan, and Co., the bankers who have succeeded in obtaining control of the majority of the stock of the Edison General Electric Company, were and are the powers behind the throne.

The coalition as arranged wipes out the Edison influence and transfers the goodwill of a business capitalised at 15,000,000dols. to the Thomson-Houston Company. The brainiest inventor of the age is asked to play "second fiddle" to Elihu Thomson, the practical man of the absorbing company. The scheme was planned by Mr. Villard and carried out before Mr. Edison realised what

was being done. He imagined that the immense financial interests he had brought into the General Company were being properly taken care of by the men he trusted. He never expected to be in a position where he would have to submit to the dictation of Wall-street manipulators.

When the details of the amalgamation plan were presented to him he frowned. It did not take him long to realise that he was in a sad minority, and that those who were engineering the scheme were in virtual control of a business that he had spent 15 years in building up. He was practically driven out of the General Company. Here is the way the situation presented itself to him:

"When the General Edison Electric Company was formed in the latter part of 1889, the Edison Electric Light Company, the Bergmann Company on Avenue B, the Edison Machine Works at Schenectady, N.Y., the Edison Lamp Company at Harrison, N.J., and the Sprague Electric Railway and Motor Company were the elements of the organisation. I owned a controlling interest in the Light Company and the majority of the stock in the Bergmann Company, the Edison Machine Works, and the Edison Lamp Co.

"I don't know what those interests were worth, but I do know that the companies that now represent 15,000,000dols. in capital under the title of the General Electric Company were practically controlled by me. Now, there is not, under the old separate organisations, even a suspicion of controlling power in my name."

Samuel J. Insull is the second vice-president and general manager of the General Company. He has been associated with Mr. Edison for a number of years. He was Edison's agent in London, and was invited to assume a responsible position in this country.

The *Morning Advertiser* learned on most reliable authority yesterday that a secret meeting was held between Messrs. Villard, Edison, and Insull a few days ago. Mr. Edison protested against the amalgamation, and Insull attempted to back up his chief. Villard turned on Insull, and said: "If it had not been for your gross mismanagement of the affairs of this great concern it would not have been necessary to enter into any such coalition as has been promulgated and is likely to be consummated by the stockholders at the meeting in May."

It is safe to say that Mr. Edison does not know exactly where he stands in the new deal. It was reported in Wall-street yesterday that the absorbing corporation would throw him out of the directory as soon as the amalgamation was completed. There is no truth in the rumour. It is well known that the Thomson-Houston people and their Wall-street friends are only too anxious to utilise Mr. Edison's brains.

The one question now is, Will the Wizard remain on the board of a concern that he knows is managed and controlled by rival inventors? A friend said yesterday, "It isn't a case of Edison being ousted from the board of directors; it is ten chances to one that the manipulators will not be able to keep him with them."

Samuel J. Insull will probably be deposed from the executive board and the general management. E. A. Coffin, of the Thomson-Houston Company will, it is said, take his place, and Mr. H. McK. Twombley will be the new president. Mr. Villard's work is done. His personal and pecuniary ambition is thoroughly satisfied.

The salary of 50,000dols. that attaches to the office of president he cares nothing for, as he declared some days ago to a *Morning Advertiser* representative. "The duties of the office are too exacting for the small compensation."

Mr. Edison's friends declare that he has been taken in by Wall-street "promoters."—*New York Herald.*

OIL AS AN INSULATOR.*

BY PROF. D. E. HUGHES, F.R.S., PAST-PRESIDENT.

At our last meeting Mr. Preece kindly gave me credit for being the first to propose the use of oil as an insulator for wires conveying an electric current; and in accordance with a suggestion on his part, I should like to state upon what grounds I can fairly be considered to be the first to urge upon the electrical world the use of hydrocarbon oils, such as petroleum and rosin oil, for this purpose.

In 1858 universal regret was felt on the failure of the insulation of the first Atlantic cable. From the first successful laying of this cable the insulation gradually became worse, until in a few days all signals failed. The cause of this was supposed to be due to minute flaws in the guttapercha during its manufacture, which became worse by submersion, or that lightning, or the intense currents then used for the Whitehouse induction coil, punctured the cable at several points.

It appeared to me (from some old experiments of mine) that what we needed was some form of insulation that possessed self-restoring powers, so that, if punctured by lightning, or our ordinary working currents, the puncture should be closed by some simpler process than having to take up a portion of the cable. I thought that Nature showed us the way in which *she* restores punctures and mechanical injuries to all living objects. This is done by a flow of liquid sap to plants, or blood in animals; for if we make an incision in the bark of a tree, the sap flows out and hardens in contact with air; if we cut our fingers, blood flows out and heals the wound. Therefore, I thought that if I could enclose in a cable an insulating self-restoring medium, the cable would not become dead at the first, or even after innumerable punctures. To carry out this object it seemed to me that a thick insulating oil, enclosed between the wire and its outer skin, would perfectly fulfil the conditions required.

Faraday had shown some years previously that oil of turpentine had a high insulating property, and this gave me great hopes that I should find, by experimenting with numerous samples of oil, the kind and quality desired for my purpose. Therefore I at once commenced a long series of experiments in order to find the best kind of oil and the most suitable form of cable to carry out this idea. Knowing that I could not fairly test these oils, or a short length of cable, by our ordinary voltaic currents, I had recourse to the very high potential currents given by the ordinary frictional static electric machine. The method used was this: I charged a battery of Leyden jars to a known degree, which was indicated upon the Leyden jars by a Peltier electrometer; these jars, when charged, were put into communication with the short piece of the cable to be tested, the outside of which was coated with tinfoil, or placed in water connected with earth, and exterior of the Leyden jars. By this means, if the insulation of the few inches of cable was bad, the Leyden jars would instantly be discharged through the defective insulation; but if the insulation was comparatively perfect, the time of discharge of the electrometer was a correct measure of its insulating properties. Of course this method required that the Leyden jars should be perfectly insulated and hold their full charge for at least one hour when not discharging through a defective cable.

On making preliminary experiments on several samples of guttaperch and indiarubber-coated wires, I found a marked difference in each variety; but as these differences were of a constant character for each sample, it was easy to tell which of these had the highest insulating property. These experiments showed me that if I wished to arrive at the true value of an insulating oil I must make the experiments by a method by which the result should be entirely free from any interior or exterior coating. For this I took two small flat circular discs, 1in. in diameter, which could be immersed in oil, and by an insulated adjustable screw I could compare the striking distance of these discs in air, compared with the same when immersed in oil, and could also observe the time required for a complete discharge of the Leyden jars through this medium.

On testing numerous samples of different oils, I found not only a great difference in the species of oil, but also a great difference in different samples of the same oil, consequently a table giving the results on different oils might be misleading, as a sample of superior quality of a certain oil (although inferior in many other samples) might give higher results than a badly selected sample of a really superior oil. The only difficulty as regards rosin oil is one of manufacture, or, rather, of finding, and teaching the makers, the quality of oil best suited for the purpose; for I found, on obtaining samples of this oil from different makers, that a great difference existed as regards their insulating properties, ranging from worse than castor oil up to a degree superior to guttapercha; and this is true of most oils; consequently, before using any oil, its quality as an insulator should be thoroughly known by constant electrical tests.

In selecting oil of high insulating quality, we must also have regard to the purpose for which it is to be used. Thus, as a self-restoring medium having very quick action, for condensers, transformers, or coils so closely wound as to be difficult for a thick oil to penetrate, a thin rosin oil, such as rosin spirit, might be best; but for cables and underground wires I found thick pure rosin oil best, because it was not only superior as an insulator, but it would not escape too rapidly at any large puncture.

Experiments were also carried on at the same time to observe the effect of any given oil on thin sheets of guttapercha, indiarubber, etc. These were immersed in separate vases of different oils, they were weighed before and after prolonged immersion; the result being that some oils were found to be injurious to guttapercha, and almost all, with the exception of castor oil, were more or less destructive to indiarubber. I found, after numerous experiments, that pure rosin oil gave the highest insulation of all, for a spark that would pierce a given thickness of guttapercha would utterly fail to pierce the same thickness of rosin oil; whilst, if the guttapercha was pierced, its insulation was destroyed and could not be easily restored to its former condition; on the other hand, if by accident the rosin oil was pierced, it, by its own mobility, at once restored the insulation to its original state. Rosin oil, at the same time, had a preservative effect upon guttapercha, for the sheets immersed in this oil had become slightly increased in weight, showing that it had penetrated into the pores of the guttapercha; at the same time it was stiffer and tougher than before immersion. I will now show you an actual specimen of this fluid cable, cut off from a specimen one mile in length, made by the Gutta Percha Company 33 years since. You will observe that the guttapercha has absorbed during that time a large proportion of the oil, and that the guttapercha is now, after 33 years' exposure to the air, apparently as good an insulator as when first made.

Experiments were now made as to the value of rosin oil when employed as the sole insulator of an electric cable. For this purpose, a short length of copper wire, say, 1ft., was coated, first, by being wound by well-dried cotton or hemp, or, better still, by a string wound round in wide open spirals, in order that the oil should penetrate as freely everywhere as possible; this was afterwards drawn into a small lead tube filled with rosin oil: thus the string or fibrous covering on the wire was simply to keep the wire concentric, so as to prevent its touching any part of the exterior tube without some separation of oil or oil-saturated fibre. It will be seen that these tests were identical, both as to form and material, in their essential points, with those patented by Mr. David Brooks, of Philadelphia, some 15 years later; but as these are clearly described in my patent of January 11th, 1859, there can be no question of priority in this respect, though, no doubt,

* Paper read before the Institution of Electrical Engineers, March 10, 1892.

many improvements suggested by practical experience in the mode of laying and manufacture are original with Mr. Brooks. The insulation of this form of cable was not quite as high as solid guttapercha, due to the fibre not being as good an insulator as the enclosed oil, but its mechanical powers of self-restoration and durability seemed to me to more than counterbalance its slightly less insulating power, for even with guttapercha there are questions of strength and durability which ought never to be lost sight of in favour of a temporary high insulation; and I think that when the value of fluid insulation is more thoroughly known, especially for currents of high potential, it will be more generally used than at present, particularly as there are now no valid patent rights to interfere. I again repeated these experiments, using a thinly-covered guttapercha wire for the inner conductor, drawn into a guttapercha tube full of rosin oil. This gave me very high insulation—so much so, that I tried a bare copper wire in the guttapercha tube alone, without any rosin oil; this, to my surprise, gave a far higher insulation than the best guttapercha-covered wires as supplied to me by the Gutta Percha Company. This surprised me very much, as the tubes, which I bought at an ordinary retail shop, were known to be of an inferior quality of guttapercha. I found afterwards that this difference was due to the tubes having been long made and kept in stock; they had gradually dried, and were free from combined moisture absorbed during their manufacture. I proved this by taking some newly-manufactured guttapercha, and heating it gradually for a length of time sufficient to drive off its moisture; this, when modelled on a wire, so as to form a cable, gave precisely the same degree of high insulation as the old tubes that I had purchased elsewhere. I do not believe that the mechanical quality of the guttapercha was improved by this operation; most likely it would have soon become brittle, for humidity, or an essential oil, seems necessary to its life and mechanical qualities. I told Mr. Chartterton and Mr. Willoughby Smith, of the Gutta Percha Company, of these results, and urged upon them the necessity of well drying the guttapercha and of manufacturing their cables, if possible, without constantly macerating it in water. I am not aware that my remarks had any effect, but this I remember, that in a few weeks after they gave me a sample, which they called "special guttapercha," which certainly had as good insulating qualities as my dried guttapercha.

As I have already said, my main object being to produce a self-restoring insulation for cables and underground wires, I found that a thin fluid, such as rosin spirit or petroleum, might be objectionable, as at the point of fracture or puncture the fluid might escape with so great a rapidity as to be somewhat costly in its maintenance; but by employing a thick, heavy, insulating oil, whose rate of flow would be small, this would displace any water in the puncture, provided that there was a slight head-pressure given to the oil at a reservoir at certain landing stations, then it would answer all practicable purposes. For this I preferred rosin oil, which is already a thick, viscid oil, and can be made more so by the addition of solid rosin dissolved in it, or by the addition of palm oil residue, which has a remarkable property of thickening resin oil. In order to satisfy those who might object to even a very small leakage of oil at the puncture, I made several compounds of rosin oil, mentioned in my patent, that should harden when in contact with water, and thus prevent any waste of oil at the fault or puncture. This static charge which I used was of high potential; the sparking distance in air, of the charge used, was about 1in., and it showed the remarkable insulation of rosin oil when $\frac{1}{64}$in. separation would effectually prevent such a spark passing through it. After having found this high insulating property of rosin oil, I coated all my Leyden jars and all parts where I desired high insulation with it, and by this means I was enabled to retain a full charge of the Leyden jars for several hours, in an atmosphere full of humidity. They have lately proved the value of oil insulation in Frankfort by the use of oil in transformers of 20,000 volts, and I am convinced that in all cases where we need a high insulation, together with the power of self-restoration, it can only be found in fluid insulators. It is useful in every case where it can be applied; it is far cheaper than guttapercha, and I have no doubt that it will soon be used for insulation in condensers as well as transformers. Mr. Nikola Tesla, in his late charming lecture, spoke highly of the use of oil in his transformers, saying that it not only gave a perfect insulation, but had the power of restoring the insulation whenever pierced or punctured, as he believed his coils were at least several times every day. I remarked during these experiments that, no matter how high the potential, the amount of leakage was equal in time, either with a high or low charge of the Leyden jars—that is to say, when the Leyden jars were discharging at a slow rate through a good insulator, the time of falling of the electrometer through any given number of degrees was very equal throughout its whole range from 200,000 to 1,000 volts.

Being desirous of repeating this evening some of my old experiments, I applied to Mr. W. H. Preece for some of the best samples of guttapercha-covered wires as used by the Post Office, and which he has most willingly sent me. I also applied to Mr. James Wimshurst, the inventor of his remarkable static electric machine, who at once most kindly consented to lend the machine, and also design an arrangement by means of which we could show to those at a distance the different distances of the sparking through oil compared with air. On testing this apparatus with oil, it seemed to show that the value of oil as an insulator increased both with the potential of the charge and also with the rapidity of alternations, for when the experiments were made by an impulsive rush so as to have the greatest number of oscillations per second—say 1,000,000—then even the poorest oil, such as castor oil, showed marked superiority over air or guttapercha. This confirms the *advantage of oil, and its* value in connection with the rapid alternating high-voltage currents used in our transformers of to-day. The experiments which we hope to repeat this evening have already shown us that a spark, or charge, from a Leyden jar which would easily pierce 4in. of air will not pierce $\frac{1}{16}$in. of rosin oil; proving that oil, when resisting an impulsive rush of a charge, has 79 times higher insulation than air. To obtain these results we used a large and most powerful Wimshurst machine; but this evening, for convenience sake, we shall use a smaller machine. We may not be able to obtain quite as high comparative values, still we hope to obtain results showing oil to be 50 times better an insulator than air. With the largest machine we obtained the following remarkable effects. The apparatus for holding the oil was a glass vase, 4in. in diameter by 3in. deep. The lower portion of this vase had a copper plate connected with one portion of the circuit. A brass knob, $\frac{1}{2}$in. diameter, connected with the other portion of the circuit, could be raised or lowered in this vase in order to show the different striking distances when the vase contained air or oil. This gave the comparative results already mentioned; but, in addition, we noticed that when the knob was only covered three-quarters with oil, the spark rose from the upper portion to the upper portion of the vase, and then descended on the outside in order to reach the lower copper plate—a course of some 5in. through air, compared with $\frac{1}{16}$in. through oil. If now the current was increased, the current, or spark, became a continuous sheet flow all over the entire surface of the vase, resembling in appearance a waterfall, or exactly imitating the well-known Gassiot cascade. On again increasing the charge, in an attempt to pierce the oil, the spark pierced the glass vase, making a small hole of about $\frac{1}{32}$in. diameter, at a place $\frac{1}{2}$in. above the surface of the oil; thus the spark preferred to pierce the glass and travel several inches through air, rather than traverse a distance of $\frac{1}{16}$in. through oil. I will now show several forms of oil insulation as applicable for submarine or subterraneous wires, and the remarkable power of self-restoration when the insulation is temporarily destroyed by a puncture or cut across so as to lay the wire bare for an instant.

It will be seen in the experiments following this paper that I have arranged a battery so that one pole is connected through a sensitive galvanometer to a metal tank containing salt water, the return circuit being completed through the salt water and wire to be tested to the other pole. If we take any sample of guttapercha-covered wire and place it in the water, the insulation seems perfect and all that could be desired; but if we make a small incision with a knife, so as to leave a minute portion of the copper exposed, then, as we already know, on placing this in the tank, the water at once percolates through the cut to the wire, and its insulation is completely and permanently destroyed. If we try this same experiment with oil cable, such as a bare copper wire in a guttapercha tube containing oil, or, better still as a proof, a thinly-coated guttapercha wire, and this plunged into a small lead tube containing thick rosin oil, the whole having the same diameter as the guttapercha-covered wires, we find on testing this lead-covered oil cable that its insulation is as perfect as the guttapercha wires. If we now cut through the lead tube and the guttapercha wire once or several times, so as to lay the wire bare, the insulation for an instant is destroyed, but in less than a second the oil percolates through the wound or cut, and its insulation is instantly restored to its previous high value. I believe that these experiments sufficiently show the merits of a self-restoring insulating medium, such as rosin oil, for all purposes where a permanent insulation of wires conveying an electric current is desirable.

In conclusion, I will mention a few proofs of my claim to be the first to recognise the value of oil insulation for wires conveying an electric current, based upon some earlier experiments, but patented January 11, 1859, entitled "An Improved Mode of Insulating Electrical Conducting Wires," which describes and claims most of that which I have already related. I will read a few sentences, in order to prove this fact. After showing how the oil may be applied to submarine cables, and in order to claim its application to underground wires, the specification says (page 3, line 10): "With some trifling modifications, the invention may be also applied for insulating electrical conducting wires employed on land or underground." As regards the materials used, it says (p. 4, line 23): "I propose and prefer to use rosin oil, rendered sufficiently thick or viscid for the purpose by the addition of rosin or the solid residuum obtained from the distillation of palm oil." In order to show that the interior wire may be covered with a fibrous material instead of guttapercha, it says (p. 4, line 34): "Instead of bringing the soft or semi-fluid restorative medium in direct contact with the enclosed wires, I sometimes first coat the wires with a non-conducting material, such as guttapercha or indiarubber, and if preferred, the wire may be previously covered with some fibrous material." My invention being as well adapted for numerous wires in an underground cable as in a single-wire cable, it says (p. 5, line 6: "And the invention is as applicable when two or more electrical conductors are placed in one common tube or outer covering as when only one conductor is employed." If the patent is hurriedly read, it would seem as if I only intended to use the oil in connection with guttapercha cables; but I foresaw the use of other outer covering, such as lead or iron tubes, for it says (p. 4, line 37): "The insulated electrical conductor thus coated or covered is then placed in a guttapercha or other tube." This phrase "other tube" referred to my experiments with an outer tube of lead or other metal; and I again employ the same phrase at page 5, line 13, where it says that the wires surrounded by the rosin oil "may be placed in the guttapercha or other outer covering." A paper on this subject was read before the Society of Arts and published in their *Journal* April 15, 1859, in which I demonstrated by practical experiments the restorative powers of my fluid insulation.

Sir William Fothergill Cooke, the chairman, in reply, spoke in praise of the results, and said he "also thought the invention would be very valuable as applied to the street wires of electric telegraphs, and these afforded more facilities for testing its value." So it cannot be said that its applicability to underground wires was not foreseen at that date. From 1858 to 1860 I tried by every means to get the various land and submarine electric telegraph companies to try this system, but in vain. I thus lost two years of valuable time, and then went to France in connection with my printing telegraph instrument, to which I devoted my whole time for many succeeding years, thus practically abandoning my self-restoring fluid insulation to the public. The cause of its failure to be used then was due to the fact that the invention was made before its time, or that the need of its use was not then as great as at the present time. I am glad to say that now, thanks to electric light and power, the use of a self-restoring oil insulation is fast coming into actual practice under the names and patents of numerous succeeding inventors; so I sincerely thank Mr. Preece for citing my early work, and thus giving me this opportunity of claiming as priority the work that I had done before and patented in 1859.

My best thanks are due to Mr. Preece for the samples of gutta-percha, wires, galvanometer, etc.; to Mr. James Wimshurst for the loan of his static electric machine, and for his great assistance in preparing some of our experiments on high-tension currents; also to Messrs. Grindley and Co., of Upper North-street, Poplar, for having supplied me with numerous samples of their best oil, from which I have selected the oil that I have used this evening.

ELECTRICAL TRACTION AND ITS FINANCIAL ASPECT.*

BY STEPHEN SELLON.

Considerable difficulty has been experienced in obtaining reliable statistics in connection with electrical traction as regards its alleged economy over other motive power. The author has therefore devoted considerable attention to this subject, and has, through his connection with electrical companies, been able to collect information which may be considered reliable. In claiming certain advantages for one system over another, especially as regards initial cost and working expenditure, the author has purposely adopted a somewhat dogmatic tone as an incentive to promote criticism and useful discussion, and for this purpose, especially as regards the commercial question, is this paper suggested as a means of ventilating this most interesting subject.

The well-known systems of electrical traction before the public are the following:

1. Accumulators, consisting of the E.P.S. and the Julien types.
2. Overhead, consisting of the Thomson-Houston, Edison, Sprague, Short, Rae, United Electric Traction Company, Daft, and Van Depoele types.
3. Conduit, consisting of the Lineff, Gordon, and Wynne types for closed conduits; and the Waller-Manville and Blackpool types for open conduits.

For the purpose of convenience the author will consider each system in the above order.

Accumulator System.

This system of traction, which involves carrying the necessary power stored up in the cars by means of storage batteries, has been attempted to a small extent in America, Brussels, London, and Birmingham. Having no exposed conductors, the system is favourably looked upon by local authorities and tramway companies. As a mechanical means of traction it is workable and very fairly satisfactory. In a commercial sense it has proved a failure. Apart from its features of rapid depreciation and great weight, the accumulator system of electric traction is preferable to any other. Its chief defects are (1) a great increase to the tare weight of the car, varying from five to six tons—most horse tramways are not built strong enough to receive this additional load; (2) the rapid deterioration of the plates (estimated at nearly 200 per cent.). and requiring frequent renewals. No reliable figures have been given as to the operative expenses of the accumulator system, but its abandonment at Brussels and in America is suggestive of commercial failure.

On the Birmingham Central Tramway, it is stated, by a report of the directors issued August 11th, 1891, to be a success, but no item is given for depreciation, as compared with other methods of traction. The following table gives the working expenses per car mile for the four different systems of traction in use by this company:

Working cost	per car mile	with	steam	10·99d.
Working	,,	,,	horses	9·79d.
Working	,,	,,	cable	6·33d.
Working	,,	,,	electricity	9·90d.

It is worthy of note that this tramway company, in an extension Bill last session, fought the telephone clauses most vigorously, and on being defeated they abandoned their Bill. This action would point to a disbelief in self-contained cars, to which the telephone clauses do not apply, and that the directors realised the necessity of seeking powers for the establishment of a different system in the future.

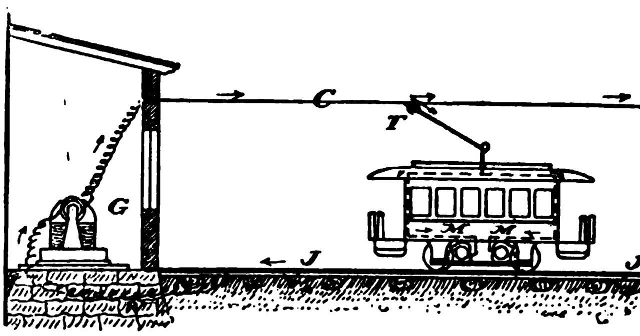
The National Telephone Company over the whole of their system use the earth as a medium for their return circuit. The current used by them is so exceedingly minute that any larger current disseminated through the earth in the same neighbourhood creates such a disturbance by induction as to render the telephones practically useless.

For this reason the telephone company has, in late years, made a most vigorous opposition in Parliament to any tramway company asking for electrical powers, unless they accepted certain telephone clauses in their Bill; these clauses practically allocate the use of the earth for telephone circuits alone. In view, however, of the opinions expressed by Mr. Preece, the electrical engineer to the Post Office, and other authorities, the author was the first to refuse to accept the introduction of these clauses in a Bill he had the conduct of, and he succeeded in convincing a committee of each House of Parliament that the earth should be a common property, and each company must protect themselves from external electrical influences.

In consequence of an alleged disturbance to the Leeds telephones by the working of the Roundhay Park electric tramway, the Act for which contains no telephone clauses, an action for damages has commenced between the National Telephone Company and the Roundhay Tramways; the result will be looked forward to with interest by the tramway and electrical world.

The Overhead System.

This system, which is to be seen now in operation on the Roundhay Park section of the Leeds Corporation tramways, is the first introduction of its kind into England, and the author was one of the parties concerned in obtaining the concession.* The line is $5\frac{1}{2}$ miles in length, and has now been working for more than three months. The fact that the Leeds Corporation have lately granted an extension of the system speaks well for its popularity. The diagram shows the method adopted for supporting the trolley wire or conductor. Six cars, each carrying two 15-h.p. motors, serve the line, and the generating plant consists of a single high-speed engine belted to two 80-h.p. dynamos; the whole of the electrical work was supplied by the Thomson-Houston Company, of America.



The marvellous development of this system in that country during the last six years is shown by the following table:

In 1885	there were	3	roads equipped with	13	motor cars
,, 1886	,,	5	,, ,,	39	,,
,, 1887	,,	7	,, ,,	81	,,
,, 1888	,,	32	,, ,,	265	,,
,, 1889	,,	104	,, ,,	965	,,
,, 1890	,,	126	,, ,,	2,000	,,
,, 1891	,,	405	,, ,,	5,099	,,
,, 1892	,,	436	,, ,,	5,851	,,

The following are the principal firms supplying installations on this system and their mileage extent:

	No. of roads.	Mileage.	Motor cars.
Thomson-Houston	200	2,113	3,040
Edison (Sprague)	167	987	2,061
Short	26	180	301
Rae	36	157	278
United Electrical Traction Company (Daft)	20	62	116
Van Depoele	7	33	55
Total	436	3,532	5,851

Beyond mechanical details the principle is substantially the same with each firm. The Thomson-Houston has the largest business, which the author thinks is owing to an elaborate system of testing and inspection before work is allowed to leave their factories, and to general excellence in detail work which has prevented the unfortunate failures in motors, etc., which were so frequent in the earlier days of electric traction. They cannot claim, however, either cheapness or superiority of manufacture.

The objection to the general introduction of the overhead system in England is the necessity for an overhead conductor and the erection of standards in the streets. This is, however, in some measure an insular prejudice soon to be removed, and though it is doubtful whether the overhead system can be introduced in the centre of large towns, it will, without doubt, be largely used in the suburban districts. Within the last few months such towns as Walsall, Leeds, and Bradford have assented to its adoption in their outskirts. It is without exception the cheapest in initial cost, but the working expenses, though less than those of accumulators, are not necessarily less than the working expenses on the

* A paper read before the Society of Engineers on Monday, March 7.

* This tramway was fully described and illustrated in our issue of November 6, 1891.

conduit system of electrical traction. Statistics received from America show a large increase in revenue and a decrease in working expenses of tramways after its adoption, and in dealing with these figures it is necessary to remember that as the Railway Commissioners in America have the power to reduce tramway fares on publication of good dividends, it is against the policy of the various companies to publish returns showing large profits.

The following show the working expenses of some of the best known electrical tramways as against horse, steam, or cable traction. In comparing English and American statistics it is necessary to remember that the percentage of working expenses in America is larger than that in England, owing to labour being much dearer and also the extra price of coal where mechanical power is used. According to the reports issued by the Railway Commissioners in America for the year ending June 30th, 1890, the average working expense of horse tramways is 79 per cent. of the gross earnings. The average working expense of horse tramways in England, according to the Board of Trade returns, is 77 per cent. of the gross earnings.

The largest street railway system in the world is the West End, Boston, Mass. Electric traction is fast supplanting horse traction on this line. In June last the mileage proportion between horse cars and electric cars stood at 3 to 1. The operating expense by horse traction was 66·70 per cent. of the gross earnings, while that of electric traction was 47·70. The electric cars are operated on the same lines with horse cars, and at present the former run about 25·15 per cent. of the entire mileage. The popularity of the system is shown by the fact that the electric cars earned £5,555 more than their proportion of the mileage. If the system was extended over the whole line the increased net earnings on these figures would have been over 52 per cent. of the present earnings. The increase of traffic due to the substitution of electric traction for horse traction on this tramway is 44·1 per cent.

In April and May the cost of operating (motive power) per horse car was		....	5·38d.	per car mile.
In June	ditto	ditto	5·14d.	,,
In April the cost of operating (motive power) per electric car was		....	3·79d.	,,
In June	ditto	ditto	3·64d.	,,
In July	ditto	ditto	3·47d.	,,

Taking the months of April, May, June, and July, the electric cars increased their earnings per mile run from 16·86d. in April to 18·97d. in July. For the same months the horse cars increased their earnings per mile run from 15·73d. in April to 18 11d in July.

It cost in April,	per mile run,	horse cars	....	12·65d.
,, ,,	,,	electric cars..	.....	10·77d.
,, July	,,	horse cars	....	12·06d.
,, ,,	,,	electric cars....... .		10·14d.

On examining the returns of this tramway it appears that the net earnings per car mile of the electric system over the horse system is 4·98d. There are two reasons for this. First, economy of working, and second, increase of traffic due to what may be called "public satisfaction." If this amount is divided into two parts, one part representing the former and the balance the latter, we find that the operating expenses of the horse line exceed those of the electric by 1·92d. per car mile; subtracting the difference of earnings from the difference of expenses the result is 3·06d. per car mile, which amount represents the net profit of electric lines over horse lines due to "public satisfaction."

In another example it is shown that a certain tramway six miles long worked by horses up to September 30th, 1889, making an annual mileage of 87,708 car miles, earned, with five cars, £1,500 net. The following year on the same tramway worked by electric traction with the same number of cars, 117,450 miles were run, and the earning capacity of the road was increased 37½ per cent. over that of horse traction, while the operating expenses per car mile were reduced from 8·4d. to 6·9d.; in other words, the net earning capacity of the road was increased £1,740 per annum at an increase of cost of £350.

In another case eight horse cars worked a road at 63 per cent. of the gross receipts. On eight electric cars replacing the horse cars the working expenses were reduced to 53 per cent. The Minneapolis street railway, having 120 miles entirely equipped and worked by the overhead system, has just issued its first report. It shows gross earnings for July £22,133, operative expenses £10,819, or 49 per cent. of the gross earnings. The Louisville Railway Company, in their report for the year ending 1890, put the cost of working by horses at 68·36 per cent. of the gross earnings, and the cost of electric traction at 51 56 per cent.

The Denver Electric Tramway Company state the cost of operating for seven months for the year ending 1890 at 55 per cent. of the gross receipts. These tramways are some of the most important in North America. In an official census published in April by the United States Government statistics of the working of 30 horse, 10 electric, and 10 cable tramways were given. The results were as follows: Horse per car mile 8d., cable per car mile 7d., electric per car mile 6·30. It should be noticed that operating expenses include general expenses, track and car expenses, and motive power, including drivers and conductors.

THE CONDUIT SYSTEM.

Where the overhead system is objected to, tramway companies must turn their attention to the conduit system, of which there are two types—viz., the closed conduit and the open conduit. Of the former we know little, and it has never been commercially applied. The Lineff system is a closed-conduit type, of which a few yards of experimental track has been laid down in the Hammersmith depôt of the West Metropolitan Tramways. In this system an exposed rail is bolted to a tee-iron, which is buried in the track in asphalte; underneath the flanges of the rail and tee-iron is left a small chamber containing a copper conductor laid on glazed tiles, and on the top of this a strip of galvanised iron; the surface rail is in electric and magnetic contact with an electromagnet carried under the car. The electromagnet, while passing over the short lengths of insulated surface rail, attracts upward the loose strip of galvanised iron, and thus a contact is made with the copper conductor, forming an electrical connection between the copper and a few lengths of the insulated rail under the car; the current then passes through the body of the electromagnet and thence to the motor. This is really an old abandoned system under a new name. Since this was written the author is informed that three miles of this system is to be immediately laid down on the West Metropolitan Tramways.

The Wynne and the Gordon systems would appear at the present time to be still in the experimental stage.

Looking at the closed-conduit system from a commercial as well as from a technical point of view, it is as at present before us open to three grave objections: firstly, the necessity of putting short lengths of surface rail temporarily into circuit by means of some electromagnet device appears too complicated to be reliable in working; secondly, the practical impossibility of making such a system thoroughly insulated in a street subject to heavy traffic; and thirdly, supposing these two difficulties to be overcome, the impossibility of ensuring a proper contact when the road is covered with water, dirt, or snow, and the impracticability of laying short lengths of rails with sufficient rigidity in a street where there is heavy traffic.

Until further practical demonstrations of its working are forthcoming, it is useless discussing it any further in this paper.

In the open-conduit system the electrical power is taken from a conductor placed in a conduit built either under one rail or in the centre of the track. Apart from any difference of capital cost it is superior to the cable, especially in working, as the cars can travel either way by reversing, and at a variable speed, at the will of the driver, which is impossible in the cable system.

The only example of the open-conduit system in England is the Blackpool tramway, built by Mr. Holroyd Smith. This line has been worked commercially since 1885 with considerable success. Last year Sir George Bruce and the author went carefully into the working expenses of this tramway on figures supplied to them by Mr. Woodley Smith, the accountant and auditor for this tramway and the London tramways. This line was found to be working at an average percentage of 35 per cent. of the gross receipts, and was an improving property, as the following dividends will show: In 1888 it paid 4 per cent.; in 1889, 7 per cent.; in 1890, 7½ per cent. As a first attempt, all credit is due to Mr. Holroyd Smith for the way in which this installation was put down, but there are many features in it which do not warrant it being called *the* conduit system of the future.

Built along the public promenade, it has but few of the difficulties to contend with in obtaining perfect insulation which would be met were it laid in a public street, subject to the dirt and mud inseparable from ordinary street traffic. The continual action of the spray in winter from the sea produces leakage, showing that the system is deficient in perfect electrical construction. The conductors are laid on what Mr. Holroyd Smith calls porcelain insulators fixed in creosoted wood; when all this is wet imperfect insulation must ensue, and much more so when covered with wet mud. This being so under the very favourable conditions at Blackpool, it is probable that the leakage would be so great, were such a line laid in an ordinary street, as to practically prevent working. The conduit construction on this line is designed too weak to support the ordinary vehicular traffic of public streets.

Owing to the many faults both in mechanical and electrical application of electricity to the conduit system at Blackpool, the Waller-Manville system has been produced. It is somewhat misleading that this arrangement of enclosing conductors and contact wires in conduits should be termed a system, inasmuch as it involves no new method of distribution, but merely consists of a number of well worked out mechanical details to render the application of the conduit, as exemplified at Blackpool, practicable under the ordinary requirements of tramway service.

In the Waller-Manville type, the experience of a practical tramway engineer has combined with the experience of a practical electrician to produce a form of conduit traction superior to any other. The insulation is practically perfect. The conductor being a flexible cable it requires fewer supports than in the case of a rigid conductor, and these supports are situated in chambers covered with hatches similar to though smaller than those in use on cable tramways. The conductor, being flexible, can be taken out or replaced through the slot without interfering with the conduit, which is impossible in the Blackpool system. With a rigid conductor, as at Blackpool, frequent supports are necessary, so that it is impossible to provide means of access, and by reason of the infrequency of the supports to the Waller-Manville system, large insulators can be used, owing to the available space in the hatchways, whereas, in the rigid conductors the supports are necessary in the conduit, and liable to become covered with mud, and, as before pointed out, they cannot be got at for the purpose of cleaning or renewal. Every precaution is taken against the introduction of dirt. The whole has been designed so as to be constructed at a cost that will compare favourably with any conduit system.

THE COMMERCIAL QUESTION.

Being entirely governed by capital cost, working expenditure, and depreciation, a hypothetical case of three miles of tramway is taken, and as it is very difficult to apply the cable system to a single line with passing places, a double track example is taken,

and one gradient of 1 in 20, 880 yards long in the centre of the system, is assumed. It is proposed to furnish the same with an equipment sufficient for a 10 minutes' service by horse, cable, or electricity, including the overhead and conduit systems. The capital cost and average working expenditure of each system has been carefully compiled from such detailed information as has been obtainable, and is verified by the author's own personal knowledge and experience.

In the estimates of capital cost any allowance for depôt buildings and land has been excluded, as, although the figures would show somewhat in favour of mechanical systems, they might be taken for this purpose as costing about the same in each case; and as the value of land varies in different localities and the cost of a depôt is a very variable item in accordance with the class of work which may be put into it, it is better on the whole to exclude this item. The capital cost expended on the construction and equipment of a horse line may reasonably be taken at £25,800, of which £21,000 represents the cost of the tramway and the balance the equipment.

In dealing with the mechanical systems it is assumed that the cost of the construction of a horse line should be added to the cost of converting the line and equipping it on the respective systems of mechanical traction, and it has not been thought fair to charge these systems with any portion of the cost of the horse equipment, because the equipment should represent its full original value if a proper sinking fund has been provided, and on this basis the capital cost of horse, cable, overhead, and conduit lines is estimated as follows:

Capital cost of horse line	£25,800	exclusive of depôt.
,, ,, overhead line	32,000	,, ,,
,, ,, conduit line	41,500	,, ,,
,, ,, cable line	48,000	,, ,,

In regard to the working cost of these systems the figure put down (which in each case includes a reasonable allowance for maintenance and repairs) has been arrived at, as regards the horse line, from the large amount of information which is available on the subject. As regards cable traction, the last balance-sheet of the Birmingham Central Tramways Company's cable system has been taken, and the figures which they give have been adapted to the example given. It is necessary to point out that the efficiency of a cable tramway depends in an exceptional degree on the car mileage, which in Birmingham is very large. The figure arrived at in this case has been checked by reference to American statistics, and by other means, and it may be considered as a fairly accurate estimate. At any rate, it would not be safe to assume that a cable line of this size, and with the specified service, could be worked at a cheaper rate than that given later on. In the two electrical systems the actual details of the cost which would be involved has been very closely gone into. The estimates given are very sufficient, and there can be no reasonable doubt whatever that such a line could be worked at the price stated. There is no appreciable difference in the cost of working an overhead and a conduit system. It should also be stated that these estimates, besides including maintenance and repairs, as above stated, also include the cost of the car drivers, which is a very considerable amount, and is not infrequently omitted in estimates of cost of traction. The following are the figures, the rate per car mile being based on car mileage of 197,000 per annum:

	Per annum.		Per car mile.
Cost of working horse tramway	£5,750	equals	7·0d.
,, ,, cable ,,	5,750	,,	7·0d.
,, ,, overhead ,,	3,200	,,	3·90d.
,, ,, conduit ,,	3,200	,,	3·90d.

In order to compare the relative conditions of working with horse or with one of the mechanical systems referred to in the preceding estimates, it is assumed that in order to raise the extra capital required for each of the mechanical systems over and above the capital necessitated for a horse line that debentures must be issued at 5 per cent., so that the original capital for all the systems will be the same as for a horse line, and this capital has been taken at £35,000, being an extra sum of £9,200 to cover cost of depôts and working capital beyond the figure of £25,800 included in the preceding estimate. The amount of debentures to be issued would, therefore, be as follows:

Overhead line £6,200, equal at 5 per cent. to £310 per annum.
Conduit line £15,700, equal at 5 per cent. to £785 per annum.
Cable line £22,200, equal at 5 per cent. to £1,110 per annum.

The debenture interest must, therefore, be added to the working cost of each of the mechanical systems in order to compare them directly with a horse line. We therefore have the following figures of working cost:

	Ordinary working cost.		Debenture interest.		
Overhead line	£3,200	plus	£310	equals	£3,510
Conduit line	3,200	,,	785	,,	3,985
Horse line	5,750	—	—	—	5,750
Cable line	5,750	,,	1,110	,,	6,860

These preceding figures show that for a line of this description a cable tramway is more expensive to work than a horse line after making provision for the debenture capital involved by the cost of reconstruction. The following figures show the amount saved per annum by the overhead and conduit systems as compared with a horse tramway:

Overhead	£5,750	minus	£3,510	equals	£2,240
Conduit	5,750	,,	3,985	,,	1,765

and these amounts show an increased dividend available on the ordinary share capital, £35,000, upwards of 6 per cent. per annum in the case of the overhead line, and upwards of 5 per cent. per annum with a conduit line.

LEGAL INTELLIGENCE.

THE LANE FOX CASE.

The important action of Lane Fox *v.* Kensington and Knightsbridge Electric Lighting Company, Limited, has been progressing before Mr. Justice Smith in the High Court of Justice, Chancery Division, for 10 days. We intend to fully refer to the case upon its conclusion. Meanwhile, the following statement of the case will be of interest.

At the conclusion of Tuesday's proceedings, his Lordship said he would resume the hearing of the case on Monday next, at 10.30 a.m. Counsel for the defendants stated that they had three or four more witnesses to call, and it is not probable that the case will be finished before Wednesday afternoon, the 16th inst. We doubt if it will be finished then. The action is brought by Mr. St. George Lane Fox to restrain the defendants from continuing an alleged infringement of his patent, and for incidental relief. The plaintiff is the registered owner of letters patent No. 3,988, of 1878, granted to him for an invention for improvements in obtaining light by electricity, and in distributing and regulating the electric currents for the same, and in the means or apparatus employed therein. The infringement was alleged to have taken place by the use of secondary batteries as reservoirs of electricity in combination with a mode or system of distribution, substantially the same as that described in the specification, at the defendants' premises in or near Kensington High-street and Chapel-place, Brompton-road, Knightsbridge. The modes of distribution complained of were alleged to be (1) the use of the secondary batteries in combination with a number of lamps placed in multiple arc between two main leads; (2) the use of secondary batteries in combination with two or more systems of multiple arc distribution, in which one or more of the main leads are common to two or more of the said systems. The defences were (1) that the plaintiff was not the true and first inventor; (2) that at the date of the issuing of the writ the plaintiff was not the owner of the letters patent; (3) non-admission that the plaintiff was the registered owner; (4) want of utility; (5) invalidity of patent on several grounds, such as improper subject-matter for a patent, want of novelty, non-fulfilment of condition by filing a proper description of the invention within six months after the grant of the patent, differences between the provisional and complete specification, anticipations by prior patents and publications.

The Attorney General (Sir R. Webster) Mr. Moulton, Q.C., and Mr. J. C. Graham are for the plaintiff; and Sir Horace Davey, Q.C., Mr. Finlay, Q.C., and Mr. Roger Wallace for the defendants.

COMPANIES' MEETINGS.

LIVERPOOL ELECTRIC SUPPLY COMPANY, LIMITED.

The ninth annual ordinary meeting of this Company was held at Liverpool on Friday, 4th inst., Mr. A. H. Holmes, chairman, presiding.

The report, which was taken as read, stated that the amount of net profit available for dividend, including the balance brought forward from last year, was £7,866. 14s. 9d. Out of this sum they recommended a payment of a dividend of 4½ per cent. per annum, absorbing £6,580, adding £500 to reserve fund, and carrying forward the balance to next year's account. They considered the time had arrived when, in addition to writing off depreciation, a provision should be made for the renewal of mains and plant which might be necessary in the future, and they had therefore initiated a renewal fund, to the credit of which they had passed a sum of £1,500. The expenditure on capital account during the year (including a proportionate charge for general expenses) had been £17,122. The demand for electricity continued to increase, and the number of lamps connected with the Company's supply mains on December 31, 1891, was equivalent to 14,966 lamps of 16 c.p. each. During the year provisional orders had been granted to the Company by the Board of Trade for an additional area in Liverpool, including London-road, Prince's-road, and Prince's Park, and also for an area under the Toxteth Park local authority, including Sefton Park and the adjacent residential district. Both these provisional orders were for the full statutory term of 42 years. The Directors had obtained the consent of the Watch Committee, which had been confirmed by the City Council, to a provisional order under which the date for compulsory purchase, on the terms of the Electric Lighting Acts, of the Company's undertaking authorised by the provisional order of 1889, was postponed from 21 to 42 years; the Corporation to have the option of taking over the Company's supply business in the city of Liverpool as a going concern after December 31, 1897, at a price to be fixed by arbitration, as in the case of property taken under the Lands Clauses Consolidation Acts.

The **Chairman**, in moving the adoption of the report, announced that the business during the past year had been very materially increased, and that their prospects were very good. People were beginning to appreciate what a benefit to health and cleanliness the electric light was. The report showed that they had done a very much larger business, and that they were likely to do an increas-

ing business in the future. With the increased business they had made increased profits. The dividend of 4½ per cent. had been very fairly earned. With regard to the renewal fund, he thought the shareholders would see that it was a very wise action on the part of the Directors. The demands for their electricity had increased very much. On the 1st of January last year the number of lamps was 11,750; on the 1st of January of this year the number was 14,966; and at the present moment the number of lamps for which they had orders to supply was 16,900, which he thought was a very satisfactory state of affairs. In respect to the expenditure on capital account, it had been nearly all absorbed in extending their mains over the increased area. The extension was from Abercromby-square, up Mount-pleasant, along Bedford-street in the direction of the junction in Prince's-road up to St. Margaret's Church. Another extension would go up to University College, and also up London-road. In all these areas they had received a considerable number of promises from people who were anxious to use their light. The Directors had come to an arrangement with the Corporation by means of which the whole of their undertaking was placed on the basis of the 1891 order so far as the time went. They might consider that 42 years from now the whole undertaking was their own property, and could not be taken away from them except on the special terms mentioned in the report. In the event of the Corporation desiring to take the concern over in 1897 they would have to pay the Company such a price as would compensate them for the loss of their undertaking, and give them a fair return for the money that had been expended. He thought it was one of those happy arrangements by which all would be benefited. It would not only be a benefit to the Company, but to the Corporation and the city at large, and especially to the consumers, who would be able to get the electric light at a lower price than would have been possible had the arrangement not been carried out. He hoped that eventually, they might be able to induce the Corporation to get the work of making good the roads disturbed in laying down the mains done by contract, and also succeed in prevailing upon them to follow the examples of Manchester, Birmingham, and other larger and smaller places and have the electric light supplied to the Town Hall. He believed that they were behind Bootle in this matter. He thought it was scandalous that a great city like that, having such lovely rooms at the Town Hall, should persist in retaining the old-fashioned gas arrangement. He was pleased to say that the Electric Supply Company were on most excellent terms with the gas company.

The motion was seconded by **Mr. D. de Ybarrondo.**

Mr. J. Lister moved as amendment that the Company should pay the income tax on the dividend.

Mr. C. Birchall seconded the amendment, and hoped that there was a prospect of a considerable reduction in the expense of the lamps.

The **Chairman** replied that there was a balance on the right side sufficient to enable the Directors to do as had been proposed.

The motion as amended was then agreed to.

Mr. Goffey asked whether there was any truth in the assertion as to the 7 per cent. restriction?

The **Chairman**: It is not exactly that. There is, however, a great deal of truth in it. As soon as we reach 7 per cent. dividend, anything beyond that will have to be divided between the Company and the consumers. With regard to the cost of the lamps, I may say that when the patent expires, as it will do next year, instead of paying 4s. or 5s. per lamp, the price will be about 1s. 3d. for each lamp, and perhaps less than that.

The re-election of Messrs. A. H. Holme and D. de Ybarrondo as directors was proposed by **Sir David Radcliffe**, seconded by **Mr. Dansfield**, and carried.

A sum of 400 guineas was placed at the disposal of the Directors as remuneration for their services during the past year, free of income tax.

Mr. W. L. Jackson was re-elected auditor.

On the motion of the **Chairman**, seconded by **Sir David Radcliffe**, the meeting recorded its approval of the provisional order now being promoted by the Board of Trade, and also its approval of the amendments agreed upon between the Corporation and the Company.

A vote of thanks to the Chairman concluded the proceedings.

COMPANIES' REPORTS.

KENSINGTON AND KNIGHTSBRIDGE ELECTRIC LIGHTING COMPANY.

Directors: Alfred Sohier Bolton, Esq., Sir Fredk. J. Bramwell, Bart., F.R.S., G. H. Hopkinson, Esq., Granville R. Ryder, Esq., R. W. Wallace, Esq.

Report by the Directors presented at the fifth ordinary general meeting, held at 1, Great George-street, Westminster, yesterday (Thursday) at 5 p.m.

The Directors beg to submit to the shareholders a statement of the accounts of the Company, together with a report of the position of the undertaking at the end of the year 1891. The mains, which extended for a length of 10 miles in the previous year, have been increased during the year 1891 to 12¼ miles. During the year the number of houses and shops connected with the system has increased from 291 on the 31st December, 1890, to 436 on the 31st December, 1891, while the number of lamps, calculated on the usual basis of 8 c.p., has increased from 25,535 to 38,408. The plant at the Company's stations has been worked at a greatly increased rate of efficiency especially during the last half-year, and further improvement in this respect is still being made. Provision has been made at Kensington Court for fixing a new boiler, and at Chapel-place three new engines have been added during the year to meet the rapid increase in the demand at this station. The funds required by the Company for extension during the past year have been raised by the issue of 4½ per cent. debentures, and it has not been found necessary to issue any of the second preference shares authorised at the last meeting. The dividend on the 6 per cent. preference shares was duly paid to June 30, 1891, and out of the balance standing to the credit of the net revenue for the year 1891, £3,810. 11s. 3d., the sum of £1,462. 10s. has been appropriated for the payment of the preference dividend to that date, leaving £2,348. 1s. 3d., out of which it is proposed to pay a dividend on the ordinary shares at the rate of 2 per cent. for the year, carrying forward £848. 1s. 3d. to the next account. In accordance with the articles of association Mr. A. S. Bolton and Sir Frederick J. Bramwell, Bart., F.R.S., retire from the directorship, and being eligible offer themselves for re-election. The auditors, Messrs. Lovelock, H. W. Whiffin, and Dickinson, offer themselves for re-election.

Dr. Balance-sheet, December 31, 1891.				£	s.	d.

NEW COMPANIES REGISTERED.

Eston Arc Lamp Syndicate, Limited.—Registered by H. W. Christmas, 42A, Bloomsbury-square, W.C., with a capital of £25,000 in £5 shares. Object: to carry into effect an agreement, made February 18, between T. P. C Crampton and A Essinger of the one part, and G. W. Yorston, on behalf this Company, of the other part, and generally to carry on business as electricians and electrical engineers in all its branches. The first subscribers are:

	Shares.
A. Essinger, 19, Clifton-hill, St. John's Wood	1
T. Sturgeon, Alexander-crescent, Ilkley, Yorkshire	1
J. A. White, 38, Holborn-viaduct, E C.	1
F. E. Pearl, 27, Ivanhoe-road, Denmark-park	1
M. J. Alexander, 68, Carlton-hill, N.W.	1
W. W. Westcott, 396, Camden-road, N.	1
E. J. de Buriatti, 38, Holborn-viaduct	1

There shall not be less than three nor more than six Directors. The first are W. W Westcott, G. North, J. A. White, and A. Essinger. Qualification, 20 shares. Remuneration, £2. 2s. for each Board attendance, with a further sum of £50 for each 10 per cent. paid as dividend.

Hobart Tramway Company, Limited.—Registered by Linklater, Hockwood, Addison, and Brown, 2, Bond-court, Walbrook, E C., with a capital of £105,000 in £1 shares. Object: to apply for and carry into effect any Act of Parliament (imperial or colonial), provisional order, concession, or contract, for the establishment, construction, maintenance, or working of tramways in Hobart and in any part of Tasmania or elsewhere, and, with a view thereto. to carry into effect an agreement, made December 18, 1891, between Messrs. Symes and Grant, as agents of the Hobart Tramway Company, Limited (of Hobart), of the one part, and F. J. Warner, on behalf of this Company, of the other part; to carry on the business of an electric light and power company, as shipowners, and to establish and maintain canals, railways, and tramways, as carriers of passengers and goods, to acquire patents, patent rights, etc., and to develop and work the same. The first subscribers are:

	Shares.
A. F. McLellor, 24, Bedford-road, Tottenham	1
R. D. Wilkinson, 2, Elmwood-road, North-park, Croydon	1
C. A. Miller, 6, Carlingford-road, N.W	1
A. D. Foggo, 4, Osborne-road, Thornton Heath	1
A. Stewart, Worcester House, Walbrook, E.C.	1
G. C. Harrower, College-hill-chambers, E.C.	1
W. R. Harrower, College-hill-chambers, E.C.	1

There shall not be more than seven Directors. The first are Sir Edward N. C. Braddon, K.C.M.G., Charles Barclay, Alfred Mattei, J. W. Syme, and C. H. Grant. Qualification, 100 shares Remuneration: Chairman, £150 per annum; ordinary Directors, £100 per annum each, with 5 per cent on the net profits after payment of 10 per cent. dividend, the latter divisible.

Pioneer Telephone Company, Limited.—Registered by Davies and Sons 9, Angel-court, E.C., with a capital of £100,000 in £10 shares. Object: the general establishment and development of telephonic means of communication, and to diminish the cost thereof, and the adoption of improvements therein; to acquire lands, buildings, patents, business undertakings, etc., for the purposes of the Company; to carry on the general business of a telephone company; to establish and maintain telephonic exchanges; to advance money, to discount and deal in bills of exchange, promissory notes, debentures, and other negotiable instruments; to establish and maintain cables, stations, electric works, factories, and warehouses; to undertake and carry on all kinds of guarantee and agency business; and as company promoters, concessionnaires, and financiers; and to carry into effect an agreement expressed to be made between the Electric and General Investment Company, Limited, of the one part and this Company of the other part. The first subscribers are:

	Shares.
M. B. Praed, 189, Fleet-street	1
The Duke of Marlborough, 3, Carlton House-terrace	1
J. B. Braithwaite, jun., 18, Highbury New Park	1
F. U. Reynolds, Bromley, Kent	1
G. Herring, 1, Hamilton-place, W.	1
C. Braithwaite, 19, Lyndhurst-road, Hampstead	1
J. C. Bull, Broughton Lodge, Surbiton, Surrey	1

There shall not be less than two nor more than 10 Directors. The first are the Duke of Marlborough, Colonel the Hon. Oliver Montague, C. Praed, and F. E. Savory. Qualification, £250. Remuneration to be determined in general meeting. With slight modifications, the regulations contained in Table A apply.

"Electrical Plant, Limited."—Registered by Crouch, Edwards, and Heron, 70, Basinghall-street, E.C., with a capital of £10,000 in £10 shares. Object: to acquire the undertaking of the monthly periodical known as *Electrical Plant*, now carried on at 52, Queen Victoria-street, E.C., by Henry Sherley Price and Wallis Rivers Goulty, in accordance with an agreement expressed to be made between the said H. S. Price and W. R. Goulty of the one part, and this Company of the other part; to print and publish the same, and generally to carry on business as printers and publishers in all its branches. There shall not be less than three nor more than seven Directors. The first are H. S. Price, W R. Goulty, and H. C. Hall. Qualification, £250. Remuneration, £1. 1s. each for each Board attendance.

BUSINESS NOTES.

The Commercial Cable Company announces the payment on April 1 of the quarterly dividend at the rate of 7 per cent. per annum

New Works.—Messrs. Dorman and Smith have established new head offices and works, under the title of the Ordsal Station Electrical Works, at Salford, Manchester.

Dividend.—The Brazilian Submarine Telegraph Company have declared an interim dividend of 3s. per share, or at the rate of 6 per cent. per annum, tax free, for the quarter ended December 31, 1891, payable on the 25th inst.

City and South London Railway.—The receipts for the week ending 6th March were £893, against £732 for the corresponding period of last year, showing an increase of £161. As compared with the week ending February 28th last week's receipts show an increase of £64.

The Campbell Gas Engine Company, of Halifax, have just opened a branch showroom at 103, Snow-hill, Birmingham. The new premises are lighted by electric light, the dynamo supplying the current being driven by means of a 4-h.p. Campbell gas engine. The branch will be under the management of Messrs. A. and G. Bentley.

Companies Registered during February. — The following electrical companies were registered during the past month:

Electro-Automatic Fire Extinguishing Company, Limited, £1 shares	£12,500
Eston Arc Lamp Syndicate, Limited, £5 shares	25,000
Pioneer Telephone Company, Limited, £10 shares	100,000

Oriental Telephone Company.—The Directors of this Company have resolved, subject to audit of the accounts, to recommend to the shareholders a similar dividend to that paid last year—viz, at the rate of 2¼ per cent. on the entire paid-up capital of the Company—which dividend being only payable to the holders of ordinary shares, is equivalent to £3. 12s. 2d. per cent. on each share of 11s. paid.

Pioneer Telephone Company.—The promoters of this Company were very successful in floating their venture, applications amounting to £82,600 being received for the issue of 7,500 £10 shares offered to the public. We give some particulars as to the first subscribers, etc., to the "Pioneer" under "New Companies." If it succeeds only half as well as its electric light namesake, the Telephone Pioneer shareholders will have no reason to complain.

Electric Construction Corporation.—At a general meeting of the holders of founders' shares in this Company, held last week, the following resolutions, proposed by Mr. J. Spencer Balfour (in the chair), and seconded by Sir Daniel Cooper, were carried unanimously—viz.: 1. "That the capital of the Company be increased to £750,000, by the creation of 25,000 new shares of £10 each, numbered 50,001 to 75,000 inclusive." 2. "That the whole or any part of the said 25,000 new shares of the Company may be issued with any such rights of preference over the founders' shares, whether in respect of dividend (not exceeding a cumulative preferential dividend at the rate of 7 per cent. per annum upon the amounts credited as paid thereon) or in respect of repayment of capital, or both, and with such right of voting, and generally upon such terms and conditions in all respects as the Company may from time to time by special resolution determine." The Chairman explained that they did not intend to raise the £250,000 extra capital at once, but probably only £50,000, or at most £100,000, would be sufficient for their present purposes. The reasons given for asking for this extra working capital were the usual ones—viz., that the Company would then be able to carry out sundry large orders, which were practically only waiting for the wherewithal to do so. Subsequently, a meeting of ordinary shareholders was held, at which resolution No. 1 was put to them and carried unanimously.

PROVISIONAL PATENTS, 1892.

February 29.

3887. **A system of sending and receiving signals on telephone lines for use in fire brigades and other purposes.** Francis Elliott Stuart, Volthurst, Twickenham.

3919. **Improved method of repairing incandescent lamps.** William Stepney Rawson and Woodhouse and Rawson United, Limited, 88, Queen Victoria-street, London.

March 1.

3970. **Electromagnetic machines.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, London. (Robert Lundell, United States.) (Complete specification.)

3951. **An improved telephonic transmitter diaphragm.** Joseph Slater Lewis, 10, The Avenue, Castle Hill, Ealing.

3971. **Improvements in power-transmitting devices, especially applicable to the electrical propulsion of vehicles.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, London. (Edward Hibberd Johnson, United States.) (Complete specification.)

3991. **Improvements in electrical call and indicating apparatus.** George Richard Nunn, 6, Bank-street, Manchester.

3996. **Improvements in galvanic electric adhesive plasters.** William Phillips Thompson, 6, Lord-street, Liverpool. (John Ward Shults, United States.) (Complete specification.)

3997. **Improvements in reflectors for electric lamps.** Charles Henry Smeeton and Herbert Page, 63, Queen Victoria-street, London

4003. **Improvements in electromagnetic tools.** William Stepney Rawson, Wyndham Payne Gallwey, and Woodhouse and Rawson United, Limited, 88, Queen Victoria-street, London.

4010. **Improvements in telephones.** William Chancy Lockwood, 46, Lincoln's-inn-fields, London. (Complete specification.)

4015. **Improvements in electrical devices for stopping and starting horses.** Henry Harris Lake, 45, Southampton-buildings, London. (The Holson Electric Harness and Supply Company, United States.) (Complete specification.)

4017. **Improvements in electric measuring instruments.** Henry Harris Lake, 45, Southampton-buildings, London. (Edward Weston, United States.) (Complete specification.)

4025. **An improved means of effecting electrical communication through the medium of a clock or similar apparatus.** William Hunter Miller, 21, Cockspur-street, London.

MARCH 2.

4068. **Improvements in telephones.** Joseph Birdus Smith Booth and Ernest James Falconer, 70, Market-street, Manchester.

4097. **An improvement in the construction of electric arc lamps.** Edwin Charles Russell, 90, Cannon-street London.

4103. **Electro-deposition of aluminium on metals** Robert Goodwin, 24, Exchequer-street, Dublin.

4111. **An improvement in electromagnetic time and date stamping machines.** John Milton Glover, 52, Chancery-lane, London.

4112. **An improvement in electromagnetic postal, cancelling, time, and date stamping machine.** John Milton Glover, 52, Chancery-lane, London.

4113. **Improvements in electromagnetic time and date stamps.** John Milton Glover, 52, Chancery-lane, London.

4125. **Improvements in electrical circuit arrangements and apparatus for telegraph message signalling.** Frederick Thomas Hollins, 10, Forest-drive East, Leytonstone, Essex

4134. **Improvements in electrical visual signalling apparatus** Cornelius Edward Kelway, 122, St Donatt's-road, New Cross, London.

4152. **Improvements in electro-therapeutic apparatus.** William James Herdman, 45, Southampton-buildings, London (Complete specification.)

4154. **Improvements in electric batteries.** Emile Viarengo, 4, South-street, Finsbury, London.

4157. **Improvements in shades for electric glow lamps.** Henry William Taylor, 53, Chancery-lane, London.

4158. **Improvements connected with electric circuits for varying, regulating, or controlling the pressure of electric currents therein.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

4161. **Improvements in regulating the feed of arc lamps.** Francis Joseph Taylor, 37, Chancery-lane, London.

MARCH 3.

4185. **A new or improved automatic portable galvanic battery.** Peter Stiens, 70, Market-street, Manchester. (Complete specification.)

4186. **An improved slow-speed dynamo.** Sarah Jane Rollason, 50, Goldhurst-terrace, South Hampstead, London.

4190. **Improvements in electrical batteries.** François Marie Arthur Laurent-Cély and Etienne Finot, 2, Great George-street, Westminster, London.

4192. **Improvements in and relating to electric meters.** Francis Henry Nalder, Herbert Nalder, Charles William Scott Crawley, and Alfred Soames, 16, Red Lion-street, Clerkenwell.

4244. **Improvements in ships' telegraph.** Henry Endall, 76, Chancery-lane, London. (Complete specification.)

4247. **An electrical cut-out.** Henry Sheehy Keating, 28, Southampton-buildings, London.

4248. **Improvements in arc electric lamps.** James Brockie, 28, Southampton-buildings, London.

MARCH 4.

4258. **Improvements in the wearing parts of dynamo-electric machinery.** Wilfred L. Spence, The Elms, Seymour-grove, Manchester.

4277. **An electric motor.** Alfred Edwin Patterson, 65, Galley-wall-road, Rotherhithe.

4276. **Improvements in electrical testing instruments.** Robert William Paul and Frith Knowl, 44, Hatton-garden, London.

4294. **Cross's electrical illuminations for clocks, etc.** Walter Cross, 80, Danby-street, Bellenden-road, Peckham, London.

4311. **Improvements in dynamos.** Willoughby Statham Smith and Henry Joseph Garnett, 24, Southampton-buildings, London.

4316. **Improvements in electric welding and in apparatus therefor.** Ernest Gustave Hoffmann, 55, Chancery-lane, London.

4320. **Improvements in apparatus for regulating the arc in electric arc lamps.** Alfred William Money and Herbert Nash, 23, Southampton-buildings, London.

MARCH 5.

4341. **Improvements in the methods of driving electric railway trains.** Wilfred L. Spence, The Elms, Seymour-grove, Manchester.

4356. **Improvements in electric measuring instruments.** Walter Thomas Goolden and Sydney Evershed, Woodfield Works, Harrow-road, London.

4403. **An electric switch.** William Kirkham Partington, 61, Chancery-lane, London.

4414. **Improvements in and relating to dynamo-electric machines.** Carl Coerper, 45, Southampton buildings, London. (Complete specification)

4416. **Improvements in electric switches.** William Henry Weston and George Washington Weston, 45, Southampton-buildings, London. (Complete specification.)

4427. **Improvements in switchboard systems for telephone exchanges.** John Edward Kingsbury, 24, Southampton-buildings, London. (The Western Electric Company, United States.)

4428. **Improvements in switchboard systems for telephone exchanges.** John Edward Kingsbury, 24, Southampton-buildings, London. (The Western Electric Company, United States.)

4429. **Improvements in switchboard systems for telephone exchanges.** John Edward Kingsbury, 24, Southampton-buildings, London. (The Western Electric Company, United States.)

NOTES.

Islington.—Developments will take place at Islington shortly.

Northampton.—The cost of lighting the Northampton Town Hall was £1,628.

Bangor.—The question of a fire alarm for Bangor has been referred back to the General Purposes Committee.

Longue.—The Mayor of Longué (Maine-et-Loirè), France, invites propositions for the electric lighting of the town.

Deputations.—On Monday a deputation from the Portsmouth Town Council went round the Crystal Palace Exhibition.

Londonderry.—The Corporation of Londonderry are inviting applications for the position of consulting mechanical engineer.

Transvaal.—The Transvaal Government has given permission to the Sheba Company to lay an electric cable and to erect an overhead tramway.

Oil Engines.—The fourth Cantor lecture by Prof. W. Robinson on "The Uses of Petroleum in Engines," takes place on Monday at the Society of Arts.

Electric Central Stations.—The Corporations of Manchester and of Huddersfield are advertising for tenders for the erection of central electric station buildings.

Telephone Visitors.—The number of visitors registered at the turnstile of the National Telephone Company's telephone-room in the Crystal Palace at the end of last week was 23,221.

Portsea.—The Portsea Guardians at their last meeting were invited by the town clerk, by letter, to consider the question of electric lighting at the union house. The matter was referred to the Visiting Committee.

Electrical Measurement.—On Monday evening Mr. Malcolm Sutherland gave a lecture on "Measurement of Electricity" to the Philosophical Society, Dumbarton. He was awarded a hearty vote of thanks at the close.

Smoking Concert.—The Old Students' Asssociation will hold a smoking concert on Friday, March 25th, at the Mason's Hall Tavern, Mason's-avenue, Basinghall-street, to commence at 7.30 p.m. A first-class programme has been arranged.

Hucknall Huthwalte.—The Local Board at this town are opposing the application of the South Normanton Gas Company for a provisional order for gas, and several streets are to be experimentally lighted with oil. Electric light should be tried.

Edinburgh.—The sub-committee of the Lord Provost's Committee of the Edinburgh Town Council in charge of the electric light last week instructed the city law agent to report on the powers of the Corporation to delegate conditionally their powers with regard to electric lighting.

The Chatham Accident.—Sir M. Hicks-Beach, questioned by Mr. P. O'Brien in the House of Commons on Monday as to the death at Chatham of a man named Albert George Jay by electric shock, stated that the electric light company had been requested to make alterations.

Johannesburg. — The Transvaal Government has refused to consider the claim for £28,000 made by the Johannesburg Electric Lighting Company in respect of the lighting of Johannesburg under a Government contract; and the company has accordingly withdrawn all rights to such a claim.

Preston.—Tenders by builders and contractors are invited by the National Electric Supply Company, Limited, up to 24th inst., for works connected with central lighting station at Preston. Specification and plans on application to Mr. R. A. Came, 27, Mecklenburgh-square, London, W.C., architect.

Recorders.—Dr. C. Theodore Williams, president of the Royal Meteorological Society, in his address referred to MM. Richard Frères as "the recording angels of the nineteenth century"—if anything happened in the meteorological world, they immediately invented an instrument to record it.

Brighton.—In the proceedings of the Brighton Lighting Committee, before the Town Council last week, the Council were asked to accept Messrs. Siemens Bros. and Co.'s tender to supply the required cable with a resistance of 1,000 megohms per statute mile for the sum of £2,230—part of a sum which the Council had already sanctioned to borrow for the work. This was sanctioned.

St. Pancras.—Mr. Oswald John Simon, writing to the *Times* on Friday, complains of the inconvenience of the arrangement of the electric lamps belonging to the St. Pancras Vestry at the junction of Tottenham Court-road and Euston-road. When a large waggon comes along it is impossible for other vehicles to pass. He invites the Vestry to take steps to remove or lessen the inconvenience.

Royal Society.—Papers were read before the Royal Society on Thursday by Dr. Hopkinson, F.R.S., and Ernest Wilson on "Dynamo-Electric Machinery," dealing with important problems of dynamo construction as illustrated in the construction of the King's College dynamos. A paper was also read by Mr. R. T. Glazebrook, F.R.S., and S. Skinner, "On the Clark Cell as a Standard of E.M.F."

Pontypridd.—At the meeting of the Pontypridd Local Board last Friday, a letter was read from Messrs. W. H. Morgan and Rhys, solicitors to the Pontypridd Electric Light Company, stating that they were prepared to light the centre of the town as shown in a plan which was enclosed in their letter. The consideration of the matter was deferred, pending the result of the negotiations for the purchase of the gas works by the Board.

Sheffield Telephone Exchange.— The business of the Sheffield Telephone and Electric Light Company is, it is understood, about to be acquired by the National Telephone Company. Negotiations have been in progress for some time, and terms are now practically settled. It is understood that the business will be taken over as from the end of the present month. On the part of the National Company the statement is made that there is no disposition to raise prices.

Harrogate. — At the Harrogate Town Council on Monday, the question of putting into force the provisions of the electric lighting order was considered, and it was resolved that a sub-committee, consisting of the Mayor, Aldermen Fortune and Hammond, and Messrs. Hudson, Oxley, Simpson, and Thwaites, be appointed to make enquiry as to the best means of supplying the light in Harrogate, and, for that purpose, to inspect the installations of the light in other places.

Longest Span in England.—The span of the telephone wire over the River Dart, connecting Dartmouth with the trunk lines between Torquay and Plymouth, is 2,400ft. The wires, of silicious bronze, 17 in number, which cross the Dart, were erected in May, 1889, and the span was described by us at the time. It is some guarantee of their stability, and some credit to the Phosphor Bronze Company, who supplied them, that they have well stood

the strain of the blizzard of last year and the recent heavy gales.

Weston-super-Mare.—At the monthly meeting of the Weston-super-Mare Town Commissioners, a letter was received from the Local Government Board, in reply to the clerk's application for sanction to borrow the amount of costs incurred by the Local Board in connection with obtaining the Weston-super-Mare Electric Lighting Order, 1891, stating that it did not appear to the Local Government Board that the Commissioners had any power to raise a loan to meet the costs of obtaining the provisional order in question.

Electric Boats.—Three electric boats are being sent off this week by the General Electric Traction Company for use on the Manchester Ship Canal. The company have four electric boats in hand, one being a launch for Lord Dysart, the second a repeat order from another gentleman; the others are fresh boats for the Thames service. Quite a flotilla of these boats will be sent to Barnes for the University Boat Race, and many others, if they were built, could be hired out. Mr. George Newnes has rented the "Viscountess Bury" for the boat race.

Aberdeen.—At the meeting of the Aberdeen Town Council last week, the Gas Committee reported that they had appointed the convener (Bailie M'Kenzie), Bailie Nicol, Messrs. Bisset and Johnston a sub-committee to obtain and submit information in regard to the systems of electric lighting in those towns where it had been introduced, with powers to visit such of the towns as might be deemed expedient, and take such professional advice as they might think proper. After considerable discussion the report was adopted by a large majority.

Glasgow.—The Corporation of Glasgow has commenced operations for the establishment of the central electric station for supply of electric light to the city. The site of the station is at the corner of Waterloo and Main streets, and in addition to its erection and the fitting up of the requisite plant, there are 13 miles of mains to be laid. It is understood that there is already a good enquiry for the light by leading warehousemen. Notwithstanding these operations, it has also been found that the Dawsholm Gas Works at Maryhill will require to be enlarged.

Sittingbourne.—The new large mill at the *Daily Chronicle* paper mills, Sittingbourne, owned by Messrs. Lloyd, has been lighted by electric light. The plant consists of two dynamos driven by a 160-h.p. engine. The lamps vary from 16 c.p. to 50 c.p. A soft, clear light is diffused over the whole place, affording a marked contrast to gas. The system has given every satisfaction, so much so that the firm intend, at no very distant date, to develop it. It is not improbable that the town itself may be lighted by means of electricity, suggestions to this effect having been made in more than one quarter.

Railway Clearing House.—Tenders are required for wiring and fittings for electrically lighting the two blocks of buildings situate in Seymour-street, Euston-square, London, known as the Railway Clearing House, for the Committee of the Railway Clearing House. Specifications, schedules, and plans may be obtained on application to the secretary, on payment of one guinea. Tenders, marked on the outside of the envelope "Tenders for Electric Lighting," are to be delivered at the office of Mr. H. Smart, secretary to the committee, the Railway Clearing House, Seymour-street, Euston-square, before 11 a.m. on 30th inst.

Cork Tramways.—The report of the city engineer, Mr. McMullen, on the proposed tramways was submitted in detail at the last meeting of the Cork Standing Committee. The length is 7 furlongs 51 chains; the line will be of 3ft. gauge, using steel rails of girder section 60lb. to the yard in 30ft. lengths. The rolling-stock will consist of one-horse cars capable of carrying 24 passengers. The notice accompanying the plans stated that it is intended to seek for power to authorise the company to use horse, electrical, steam, or other mechanical power. The city engineer recommends that if electrical traction be used, it shall not be with overhead wires. The plans were approved.

Nuneaton.—At the meeting of the Nuneaton Local Board on Wednesday, the chairman drew attention to the fact that the Board's power to compulsorily purchase the gas undertaking from the private company in whom it was now vested would shortly expire. Several members considered the works ought to belong to the town, but there was a general complaint as to the bad quality of the gas that had for some time past been supplied. Mr. Butlin said that the matter was one which required serious consideration; taking into account the high price charged for gas, it was an open question whether the electric light could not be supplied more economically. The matter was adjourned for a month.

Electric Supply.—A curious circumstance is to be noticed in the returns of consumption of the Kensington Court station. The income per lamp has gone down from 10s. per lamp in 1890 to 9s. per lamp last year, a result that can only be explained by the theory that the public are becoming more habituated to the use of the electric light and take more care in turning it off when not wanted. At the same time, however, the total income has gone up with but little increase of cost—nearly three times the profit has been made with an increase of cost of only one-quarter. These facts, showing reduction in the cost to the consumer, and also in the relative cost of production to the company, are favourable auguries for the future progress of the company.

Worcester.—A meeting of the Worcester Watch Committee was held last Friday. The town clerk presented the report of Mr. W. H. Preece, F.R.S., who had been consulted by the committee for the consideration of the tenders for supplying electric light to the city. It stated that 15 tenders had been sent in from first-class firms, who had submitted very complete and practical plans. After enumerating the different firms and their methods, on the motion of Alderman Hill, seconded by Mr. Williamson, it was resolved to adopt the report, and to recommend the Council to accept the tender of the Brush Engineering Company for lighting the city by electricity. The tender was £20,030. It was stated that the annual working expenses were estimated at £3,150.

Electric Cooking.—Cooking by electricity is becoming, as we prophesied, quite the fashion. We notice that the proprietor of the Eldon Dining Hall and the Pine Apple Grill at Newcastle-on-Tyne has had trials of this novelty in cooking. At the former place on Friday some cutlets, and at the latter on Saturday a thick chop, were cooked by this new process—the cutlets in seven minutes and the chop in 14—to the entire satisfaction of the manageresses and *chefs*. We believe electric cookers are being fitted in several of the West-end flats in London. They deserve to be widely adopted. Mr. Dowsing's demonstrations every day at the Crystal Palace will greatly foster this cleanly and easy method of cooking. This will make more filling-up for station engineers' "load diagram."

Electrical Exhibition for Manchester.—A correspondent of the *Manchester Guardian* has a suggestion which, when the time arrives, should be given attention. He does not like, he says, this electrical exhibition business being confined to London. There ought at once to be an

electrical exhibition in Manchester, with the power generated by water power and transmitted to the exhibition. He does not say where from, but a few miles more or less now does not make much difference. "We really want," he says, "more development of electricity in Lancashire," and we think he is right. There is an enormous field for its utility in the cotton district—for light, for heating, and for traction and power transmission. Perhaps the exhibitors will combine and transfer their exhibits to Manchester at the end of this Exhibition.

Arc Lamps for Stations.—The new buildings in course of erection at the Glanmire terminus of the Irish Great Southern and Western Railway will not be provided with electric light. The flickering or intermittent character of the light renders it objectionable, think the directors, for station illumination, and it has been discarded in favour of gas. It is not proposed to interfere with the present system of lighting the outside works of the station. The electric light will be continued there as heretofore, we are told, as nothing can equal its brilliancy and efficacy for conducting the extensive and dangerous work of a railway terminus. If it is simply a question of flickering that prevents the use of electric light for the station, the directors might do well to investigate the merits of the Brockie-Pell arc lamp, which has shown its capabilities for absolute steadiness in many important installations.

Crystal Palace Jury.—The following gentlemen have kindly consented to serve on the jury for the Crystal Palace Electrical Exhibition: Prof. W. Grylls Adams, D.Sc., F.R.S., Prof. W. E. Ayrton, F.R.S., Mr. Shelford Bidwell, M.A., F.R.S., Mr. Conrad Cooke, M.I.E.E., Prof. W. Crookes, F.R.S., Mr. W. B. Esson, M.I.E.E., Major-General Festing, R.E., F.R.S., Prof. George Forbes, M.A., F.R.S., Captain Sir Douglas Galton, K.C.B., D.C.L., F.R.S., Dr. J. H. Gladstone, F.R.S., Mr. J. H. Greathead, M.I.C.E., Mr. Charles Hall, M.I.E.E., Prof. D. E. Hughes, F.R.S., Sir Henry Mance, C.I.E., Mr. W. H. Massey, M.I.C.E., Mr. W. H. Preece, F.R.S., Mr. A. Reckenzaun, M.I.E.E., Prof. Henry Robinson, M.I.C.E., Captain Sankey, R.E., M.I.E.E., Mr. C. E. P. Spagnoletti, M.I.C.E., Mr. James Swinburne, M.I.E.E., Prof. Silvanus Thompson, D.Sc., F.R.S., Mr. J. Tomlinson, M.I.C.E., Prof. W. C. Unwin, B.Sc., M.I.C.E., Major-General Webber, C.B., R.E., Mr. J. W. Wilson, M.I.C.E.

Electric Tanning.—The other day we received a pamphlet of the Worms et Balé process of electric tanning. We have now received the pamphlet of the rival system—Groth's tanning system—from the Chevalier Lorentz Albert Groth, 3, Tokenhouse-yard. In this system, which has been worked out at the Grange Works, Bermondsey, the hides are carried in a revolving tub or on a frame moving to and fro in a tanning liquor in which electric conductors are inserted. The rate of tannage under combined motion and electricity was four times faster than with motion alone and sixteen times faster than when neither are used. The pamphlet contains a large amount of information, with description of process and diagrammatic curves, embodying the results of the experiments, and is evidently likely to be of considerable interest, not only to leather dealers and tanners, but to all who pay attention to the practical applications of electricity. We understand the electric-tanned leather is now put on the market.

Basingstoke.—At the monthly meeting of the Basingstoke Town Council, Mr. Smith moved: "That in the opinion of this Authority, the public lighting of the town is inadequate, the charges for such lighting excessive, and that the Lighting Committee should take immediate steps to ascertain the cost of lighting it with the electric light; and that the sum of £25 be granted to them to meet the expenses of such enquiries as they may consider necessary to make." He went at length into the advantages and saving of money that would accrue if the electric light was adopted, and argued that they ought to have a better system of lighting the town than they had at present. Nearly every member of the Board spoke in favour of the resolution, with the exception of the clause relating to the expenditure of £25, and Mr. Simmons suggested that that clause should be expunged, and that the committee should report to the Board the result of their enquiries. This suggestion was ultimately accepted, and the motion as amended was approved.

Madras Tramways.—A company is being formed, with a capital of £100,000, to take over the concession granted by the Madras municipality to Messrs. Wm. Hutchinson and Co., Madras and London, for right to run electric tramways. The total length of line is 15½ miles, of which six miles must be completed with two years. It is hoped to get part of the line running within 12 months. It is expected that the line, plant, and buildings will be provided for a sum not exceeding £5,000 per mile. All material possible will be made locally. The company has applied for powers also to supply electric light for the streets, public buildings, and residences in Madras. There is no gas in Madras. Lord Wenlock, Governor of Madras, cordially approves of the project. The directors are Wm. Digby, C.I.E., chairman; M.M. Bhownuggree, C.I.E., A. J. Lusty, and S. A. Chalk, managing directors. The municipality reserve the right to purchase at the end of 21 years on payment in gold of the gross capital, with 25 per cent. added for compensation.

Meteorological Exhibition.—The exhibition of the Royal Meteorological Society includes a number of interesting instruments. Besides rain-gauges and other instruments for a station, thermometers are also shown for ascertaining the temperature on the ground, under the ground, and at a distance, as well as for recording temperature continuously. Various forms of sunshine recorders are exhibited, as well as a number of actinometers and solar radiation instruments for ascertaining the heating effect of the solar rays. The exhibition includes a large and interesting collection of hygrometers, also several rain-gauges and other instruments. Among the curiosities is a piece of plate glass which was "starred" during a thunderstorm on August 21, 1879. This was not broken, but it has a number of wavy, hair-like lines. The exhibition contains a large number of beautiful photographs of clouds, lightning, and snow scenes, as well as of the damage done by the destructive tornado at Lawrence, Mass, U.S.A. The exhibition will remain open until Tuesday, the 22nd inst.

Arc Lamps and Shades.—There is a considerable difference in the direction of light radiation from an arc lamp run on the direct-current and that from a lamp run on the alternate-current system. The difference does not seem to be appreciated by a contemporary priding itself on its popular illustrations, where the light from the arc lamps in Tottenham Court-road is seen bursting upwards very wastefully. The occasion may serve for a remark upon the use of shades and reflectors. In most cases an arc lamp run on a continuous-current circuit will be found not to require a reflector at all, as can be tested if practical trials of the loss of light are made. In an arc run with continuous current, the upper carbon forms a crater which effectually cuts off or reflects down by far the greater portion of the light, thus practically obviating the necessity for reflectors. In arcs fed by

the alternate current, on the other hand, both carbons become pointed, and the light is reflected in all directions; the necessity for a reflector in this case therefore becomes important.

Instruments and Switchboards.—We are favoured by Messrs. Nalder Bros. and Co., of 16, Red Lion-street, Clerkenwell, with their catalogue of ammeters, voltmeters, and switchboards. This shows ammeters and voltmeters of high finish and open scale for central station use, both for direct and alternate currents. A cell-testing voltmeter with spear for making contact, reading up to three volts, can be read in any position. A portable testing set for making pass tests of house installations is conveniently arranged, and a larger portable testing set with galvanometer and resistance coils adjusted approximately is specially designed for electrical contractors, self-enclosed in box. A standard voltmeter potentiometer is designed for making accurate station tests for actual measurements or for calibrating voltmeters. Holmes and Vaudrey's automatic solenoidal cut-out is designed for use with dynamos charging accumulators, or two dynamos in parallel, to complete or break the circuits when the pressure rises or falls to the required point. Resistance frames and complete switchboards are also shown.

Ludlow.—Last Friday a public meeting was held in Ludlow, Alderman Bessell presiding, to receive from the chairman and secretary of the British Electric Installation Contractors, Worcester, particulars of the requirements for carrying out an installation at Ludlow. Mr. Millington, chairman of the company, said he estimated the capital required to work the scheme at £3,500, and there would be some 2,000 lights. He calculated that the lights, at 12s. per year, would bring in an income of £1,200. The working expenses would be about £670, leaving a margin of £525. The company was proposed to be started with £1,000 debentures, 6 per cent., and ordinary shares. He recommended a storage system. The cost of installation per light would vary from 12s. to 15s. per light or more, according to fittings used. In reply to Mr. Valentine, Mr. Millington said his company would provide £1,500, the other £2,000 to be subscribed by the town. The public lighting could be carried out considerably cheaper than the present price of £300. Mr. Valentine proposed a vote of thanks to Mr. Millington, and said he hoped those gentleman present who were interested in the scheme would send in their names to form the company. Mr. Bessell seconded the resolution, which was carried.

Fire Alarms.—The order from the Poplar Board of Guardians to extend the fire alarm system throughout the two newly-built blocks, and to rewire the present system in the old buildings of the Poplar Workhouse, has just been completed by Mr. H. Hugh Headworth. The work is of a thoroughly substantial character, the wire being of the well-known Silvertown make, No. 18 indiarubber and cotton-covered, of which a mile and a quarter has been used. The whole of this is run in wood casing, with the exception where the circuits pass through walls and floors, where the wire is protected by rubber tubing. Junction-boxes with glass fronts are fixed at the junction of all main branches for the purpose of any future testing that may be required — a special and convenient arrangement. The alarm calls are of the usual bright-red enamelled iron, with fire alarm cast on, and glass fronts. These are fixed, one on each of the landings of the main staircases, access to which is open to all—a decided improvement on the system of the old buildings, where the alarm calls are fixed in the officers' rooms, and are therefore not accessible to any of the *inmates*. An indicator shows from which block the alarm has been given, the whole making a very complete fire alarm system.

Deptford Station.—The Deptford central station suffered an accident on Thursday, last week, which we were just too late to mention in our last issue. About 4 o'clock the lights began to flicker, something was noticed wrong, and the men at the station switched over to another set of mains. These went, and all four went one after the other. The natural conclusion for a while was that a railway accident down the line had torn the cables, but a workman travelling by the train arrived with the information that a fierce fire was raging down the line. It appears that Messrs. Martin and Co. use one of the railway arches as a varnish store, and this accidentally took fire while the man in charge was away, and completely gutted the premises. So fierce was the fire that the telephone wires opposite were burnt through, and the Ferranti mains were made white hot. The fire soon burnt itself out, and the telephones were got to work by 10 o'clock, and the Ferranti mains an hour later. This accident, evidently due to no fault of the London Electric Company, is the first of any kind they have experienced for four months, either in mains or transformers. They have been working with 10,000 volts since February last year. The number of lamps connected is now over 40,000. The report of the directors may be expected shortly.

Weaving by Electricity.—The City Council of St. Etienne has decided upon a departure which will have an important effect on the silk and ribbon industries both in Europe and in America. It has been resolved to apply electric motive power to all the handlooms in the city, and contracts have been made, says the *Manchester Examiner*, with an electric company for the necessary plant and currents. The electric dynamos are to be driven by water from the city reservoirs. There is practically an unlimited supply of water in the reservoirs, with a fall of upwards of 100ft. The cost of producing the electricity will be reduced to the lowest point possible. To grasp the importance and far-reaching results of this innovation, it is necessary to understand that the bulk of the enormous output of ribbons (£4,500,000 a year) is the product of house industry. The weavers for the most part own their own looms, and operate them by hand in their own houses. There are 18,000 looms which are thus distributed among the homes of the weavers, while the number of looms driven by steam in the few ribbon factories of the town is only 5,000. The 18,000 looms of the independent weavers are valued in the aggregate at £900,000. What the city of St. Etienne proposes to do is to convert each one of the 18,000 handlooms into a power loom, driven by electricity. Electric light will also be furnished. The result of this change from slow, laborious, uncertain hand power to the swift, regular, unfailing power furnished by electric motors will be an increase in the productive capacities of the looms and a considerable reduction in the general expenses of fabrication. According to the report of the American Consul, the weavers of St. Etienne have always been the most artistic ribbon-makers in the world, but they have enjoyed few mechanical advantages. Now the old order of things is to be changed, and the products of the St. Etienne ribbon looms, which have been more costly than similar products in some other countries, notably in Switzerland, will be turned out at the lowest possible prices. The workpeople employed in the ribbon trade number 70,000.

Electric Spark Photography.—The Saturday Art and Science lecture at the South Kensington Museum was delivered last week by Mr. C. V. Boys, F.R.S., on "Electric Spark Photography as Applied to Flying

Bullets and other Rapidly-Moving Bodies." The spark is generated by the discharge of a Leyden jar, there being in the conductor from it two breaks, which together the electric fluid has not pressure sufficient to jump. But when the bullet or flying object makes contact with one the spark is instantly emitted from the other. As, then, the duration of this spark may be even much less than the one-millionth of a second, it is far and away in excess of the speed of the bullet, which consequently appears to be stationary, and a very precise view is accomplished by the camera. This view records the form of the bullet, its direction and inclination, the balling up of the air in front of it, the long drawn-out vacuum in the air behind it, and the various wave vortices and contortions of the surrounding atmosphere through which it is passing. Photographs of actual experiments were then enlarged into gigantic pictures on the screen, and made perfectly clear in all their singular details to the audience. Some of the most remarkable were those which showed the passage of a bullet through a sheet of plate glass. In one the head of the bullet was seen protruding, carrying what seemed to be a dark cloud of lead vapour, caused by fusion in the impact, and another showed the storm of dust from the smashed up glass; whilst others gave views of the strains set up in the glass plate around the clean perforation the bullet had made. Clean perforations of this nature have long been known, but the reason is rendered additionally clear in that the speed of the bullet exceeds the speed at which cracks in the glass can progress. The result, consequently, is that the round portion of glass in front of the bullet is locally pounded into powder before the exterior portions have time to start into motion. Some notice was also taken of the effects of the dust and vapour envelopes of the bullet in the transmission of sound, and also how, by a series of differently-inclined diagonal perforations through the bullet, and the capacity of light being seen through them, the effects of rotation might be observed, and details of the differences of spin effected between that given by the barrel and those produced in the rapid passage of the missile through the air.

Electricity on Board Ship.—Mr. T. Crichton Fulton lectured last Friday to members of the Rutland-place Marine Engineers' Institute on "Electricity on Board Ship." Prof. Jamieson, who presided, in introducing the lecturer, said he remembered the first exposition of incandescent lamps in 1881 by Mr. Joseph W. Swan, the British inventor of the incandescent lamp, and in the summer of 1881 the wiring and lighting of part of the first steamer fitted with the electric light on the Clyde—the Cunard steamship "Servia." Since then electric lighting on board ship, as well as elsewhere, had increased rapidly, and by nobody was it more appreciated than by the passengers, officers, and crew of ocean steamers. The lecturer, after explaining the nature and peculiarities of the two forces—magnetism and electricity—proceeded to deal with his subject under two divisions: (1) how electricity was obtained; and (2) what was done with it afterwards. Under the first head he showed the relation which existed between magnetism and electricity, the production of a magnetic field by a current, and of a current by the motion of a magnet near a coil. The conditions necessary for the purpose of producing a current of electricity were therefore a magnetic field, a closed conductor in the field, and a mechanical means of causing the conductor to cut the lines of magnetic force in the proper way. He then explained the plant requisite on board ship, and mentioned the conditions essential to success. In the second division of his subject Mr. Fulton spoke of the work required of the current, and showed how it could light lamps, both arc and incandescent; drive electromotors for various purposes, and charge storage cells. The question of circuits was fully dealt with, Mr. Fulton incidentally emphasising the necessity of having all joints and connections well and carefully made. In speaking of the controlling, regulating, and measuring of the current, the lecturer explained the construction and action of switches, fuses, and resistance coils, as well as of the usual measuring instruments—the voltmeter and the amperemeter. The lecture was illustrated by numerous experiments, wall diagrams, and blackboard sketches. At the close Mr. Fulton was awarded a vote of thanks. An "Electrician," writing to the *Glasgow Herald* next day with reference to the introductory remarks by Prof. Jamieson, who stated that the first steamer fitted with the electric light on the Clyde was the Cunard steamer "Servia" in 1881, says this is not correct, as the steamer "Cosmos," built by A. and J. Inglis in 1879, had a complete installation of electric light throughout.

Electric Tramcars at Bradford.—As we mentioned last week, experiments with electric cars are about to be tried at Bradford, and the following particulars with reference to this line will be of interest. Some time ago the Tramways Committee of the Bradford Corporation decided to contribute a sum of £500 towards the cost of a trial of an electric system of traction invented by Mr. Holroyd Smith, of Halifax, and arrangements have been made for putting it to the test on a section of the Manningham tramway, extending from Forster-square to Manor-row. The method to be employed in the traction of the car is that of overhead wires; but this is not to be a permanent arrangement, as, if the motive power is found sufficient for the purpose, it is intended to adopt an underground system. The electric current, as it passes along the overhead wires, is communicated to two brass bars fixed at the top of the car. These are held up by galvanised stanchions, which have short indiarubber springs to allow the bars to relieve any sudden obstacle, and still maintain the necessary contact with the overhead wires and retain the current, which is transmitted by insulated wires enclosed in a tube at each side of the car, to the motors at the bottom of the car. The electricity will be supplied from the Bradford Corporation electrical works in Canal-road, and the motors on the car will be of 36 h.p. The overhead wires are three-eighths of an inch in diameter, and are made of the finest copper. The car, which is capable of carrying 36 passengers (18 outside and 18 inside), is the first of its kind that has been built in England, and has been constructed by the Lancaster Carriage Company from a design of Mr. Holroyd Smith. The weight of the body of the car is 2½ tons, but with the electrical mechanism beneath it the total weight is 6½ tons. The car has only four wheels, but to obviate stress in turning a sharp curve, the wheels of the car are fitted with flexible axle-boxes, which are capable of giving a lateral movement, and thus reducing the grinding movement from the wheel flanges to the rails. Special switches for the engineer and conductor are fixed to the car. One of these consists of a wheel similar to the one which controls the steering gear of a steamer, and by its use the engineer can regulate the current, which can be transmitted to each of the motors underneath the floor of the car. The conductor has thus full control over the current in each motor, and is able to avoid unnecessary waste of power. Each wheel is acted upon by the motor, so that if one is out of order it will still be possible to run the car. Special interest attaches to the experiment on account of the steep gradient on the Cheapside portion of the route, and the sharp curve from Kirkgate.

THE CRYSTAL PALACE EXHIBITION.

I.—THE TELEPHONIC EXHIBITS.

The small practical advance that has been made on Graham Bell's telephone, considered as a receiver, since it finally left his hands in 1878, is remarkable, and testifies eloquently to the degree of perfection to which it had at that period already attained. Most inventions develop slowly and, as a rule, owe their ultimate efficiency to many minds, but the telephone is an exception; it is the Pallas amongst important inventions, and practically sprang perfected from the brain of its creator. Many modifications and alterations have been tried in almost every country in the world, but it is not too much to say that were all these swept out of existence and nothing but Bell's 1878 receiver left, we should be, in a telephonic sense, practically where we are to-day. The superiority of the Ader, of the Siemens, of the Ericsson, is found in actual work to be mostly imaginary, and such difference as exists may generally and correctly be ascribed to the better workmanship and more accurate fitting of parts attendant on prolonged experience. Of the transmitting portion of the apparatus, the same may almost be said. Reis, Gray, and Edison, as Reis and the Wrays had done with the receiver, no doubt indicated the general direction of, and even travelled some distance towards, the wished-for land, but it was Hughes who was the actual Columbus, and who with his microphone, also in 1878, finally piloted us to *terra firma*. Crossley and Hunnings and Blake merely showed that the newly-discovered country contained several parishes: they found nothing beyond the borders of Hughesland.

It is this completeness of success on the part of the original explorers which explains the unsatisfactory character, as regards novelty, of the telephonic exhibits at all the recent electrical exhibitions. Edinburgh and Frankfort showed us nothing new, and Crystal Palace II. is more disappointing than either. In telephones proper there is little that has not been described many times before, so that such novelties as there are relate only to signalling, switching, and construction appliances. Even this section is incomplete. The Post Office shows nothing, and important firms like Bullers, Limited, are only noteworthy from their absence. The exhibit of the National Telephone Company, from which better things might naturally have been expected, contains not a single novelty, and is chiefly an assortment of very familiar apparatus, comprising some spoils of the law courts in the shape of instruments seized from luckless infringers.

The Western Electric Company, as befits the position which, under the able management of Mr. J. E. Kingsbury, it has assumed in this country, makes one of the best telephonic exhibits. Its transmitters and receivers, of several types and excellent workmanship, are well known, and call for no special notice. It is otherwise with the switchboards, of which three different patterns are shown. The first is the company's Standard board for 100 subscribers, with the latest improvements. The old objection of having to speak through the coils of the ring-off drop is now avoided by utilising the plan, first introduced by Mr. J. Poole at Manchester in 1880, and afterwards adopted by the Post Office at Newcastle and Bennett in Scotland, of placing the drop in derived circuit. It is satisfactory to note that American practice is now following British lead in this important particular. Poole managed with a shunt of only 100 ohms resistance, but the Western Electric apparently find it advantageous to wind their coils to 1,000 ohms in addition to making the drop an iron-clad one, precisely as Faulkner did many years ago with his "altandæ" electromagnets.* The new ring-off indicator has but one coil, which is provided with an iron casing in magnetic connection with the core. The armature is an iron disc covering both core and casing. Fig. 1 shows the general arrangement, A being the armature to which the catch, C, is joined by an arm extending the whole length of the coil, and S the shutter. With the long arm a small play of the armature suffices, and the drop is therefore sensitive. The spring-jacks, of the usual Western Electric type, are mounted on ebonite, a by no means unnecessary refinement, seeing that the earlier Standard boards sometimes suffered from defective insulation between the jacks. The method of wiring adopted is noteworthy. The indicator connections behind the board, though of small wire, are sufficiently stiff to stand out fully 4in. from the shelves, those on the same line being bound neatly together, a plan which enables any disconnection to be detected at a glance and readily repaired. Fault-finding is further facilitated by employing a differently-coloured wire for the jack connections. Terminal screws are abandoned in favour of soldered joints, another concession to British ideas.

Fig. 1.

The board is handsomely got up and admirably adapted to exchanges, worked on the indicator system, ranging up to 200 subscribers. Its one defect is that there is no means of enabling the operator to distinguish between a "ring-off" and a "ring-through." The number of movements required to make and then take off a connection on this board is eight—viz.: 1. Plugs into calling subscriber. 2. Pulls down speaking key. 3. Plugs into called subscriber. 4. Rings. 5. Puts up speaking key. 6. Puts up shutter. 7. Pulls out plugs. 8. Puts up ring-off shutter. Another good switchboard shown is of the pattern known as the Scarborough, also for 100 lines. In general construction it much resembles the Standard type, but differs from it essentially in the ring-off arrangements, although the variation cannot be regarded as an improvement, seeing that the coils of the ring-off drop are looped directly into the line when a connection is on. Separate ring-off drops are dispensed with, that of the calling subscriber being utilised for the purpose—the called subscriber's indicator being cut out by a special construction of the switch plug used for his jack. The number of movements with this board is also eight, and they are identical with those required for the Standard. The exhibit of switchboards is completed by a section of Scribner's single-

Fig. 2.

cord multiple, the patents of which are held by the Western Electric Company. The idea of this, as of all other single-cord boards, is to save time in operating by reducing the number of movements required to establish and then take off a connection, although the success attained is not usually very noteworthy, and is more than neutralised by the complication involved. The first single-cord board was introduced about 1879, in New York, in connection with the Law switching system. On the Law board each subscriber's line terminated in a cord and plug, and was also furnished with a jack. It followed that a connection could be established by lifting the plug of the calling subsciber and inserting it in the jack of the called, or *vice versâ*. The simplicity thus attained was considerable, because the Law system required no indicators; when these and cut-in keys are added, as

* *Journal, Society of Telegraph Engineers*, p. 153, vol. v., 1877.

is inevitable with any other system than the Law, simplicity flies and all practical advantage disappears. These facts are fully recognised by the Western Electric Company, which recommends its ordinary double-cord board when saving of movements is not esteemed of the first importance. The motions required for the single-cord—six in number, omitting the engaged test, which is rather a prolonged than a separate action—are: 1. Lifts caller's plug (this act makes the operator's speaking connection). 2. Plugs into called subscriber. 3. Rings. 4. Puts up shutter. 5. Takes out plug. 6. Puts up ring-off shutter. The corresponding work with the double-cord board (also omitting the engaged test) requires eight movements. The Scribner board is remarkably compact, 100 jacks occupying a space only 10½in. by 2¾in., and 40 indicators 14¼in. by 5¼in. As in the Scarborough, the ring-off coils have to be

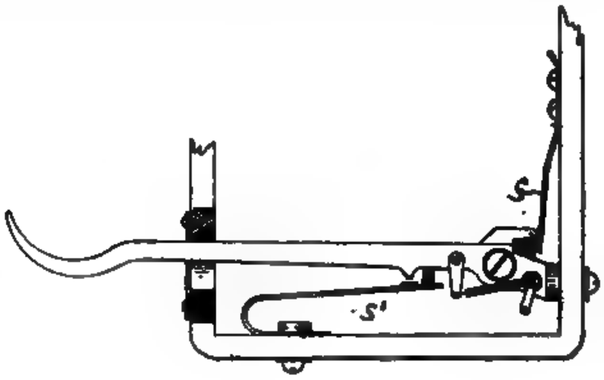

FIG. 3.

talked through by subscribers, and the operators have no means of knowing, when the drop falls, whether the conversation is finished or one subscriber is merely ringing the other. These are blemishes which must disappear before telephonic switching can be admitted to have reached its highest level. Many excellent instruments make up the exhibit. Amongst these, a handsome table set, Fig. 2, of new design is conspicuous. The transmitter, a modified Hunnings, may be turned in any direction; the receiver is of the company's well-known double-pole type, and the magneto is fitted with the latest American pattern of switch arm, Fig. 3, the chief characteristics of which are the length of leverage and the reciprocal action of the springs, S S¹, which alternately assist each other to make contact according to the position of the arm.

twisted wires. The new, or "dry core," cable is understood to be already in very extensive use in the United States, where it is employed in preference to the older type of Western Electric cable, which was insulated with dessicated cotton soaked in paraffin.

Messrs. Anders Elliot and Chetham-Strode, Limited, show a variety of telephonic instruments, some of which are of novel and ingenious design. Microphones are generally supposed to be efficient in proportion to the number of pencils they contain, but we have here a single-pencil transmitter which acquits itself very creditably. The pencil, P (Fig. 4), is mounted horizontally on the two

FIG. 6.

carbon blocks, B B¹, which are firmly attached to the ebonite diaphragm, D. The efficiency of the instrument is due to a carefully adjusted weight, W, in disc form, which is fixed to the middle of the pencil and prevents it from jumping from its seats in the blocks. The simplicity and cheapness of the transmitter recommend it for small private installations. Machines for obtaining telephonic connection from Call Offices by means of penny-in-the-slot arrangements have multiplied exceedingly since Messrs. W. Emmott, J. J. Mann, and J. Poole started the idea almost simultaneously in 1884. Some of these are good, though most are indifferent, but few, if any, in either category, can compete in simplicity with the little instrument exhibited by this firm, and illustrated in Fig. 5, which shows the apparatus in two positions. The exchange can only be called by effecting

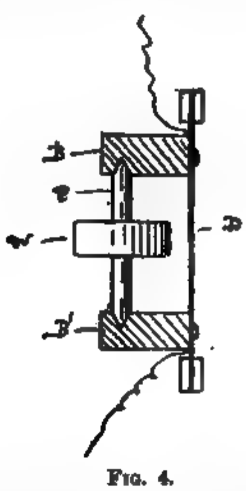

FIG. 4.

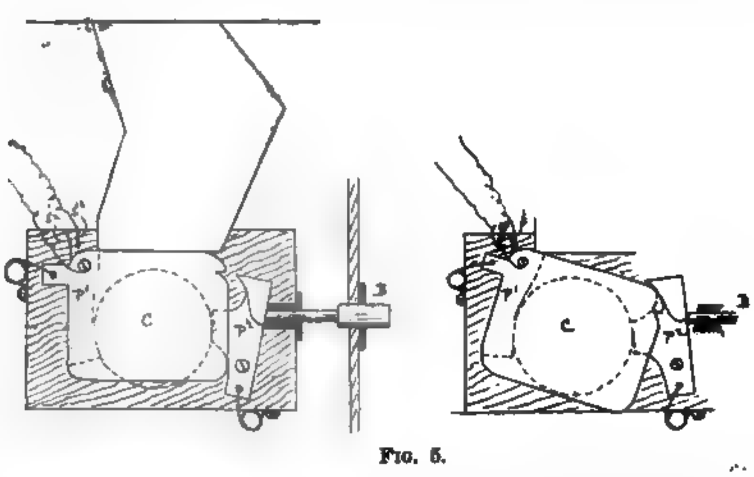

FIG. 5.

Not the least interesting are the samples of telephonic cables manufactured by the Western Electric Company. The recognition of the great importance of low inductive capacity in telephone work has induced the preparation of a new cable, which, with a conductor of No. 18 American gauge, is guaranteed to test only ·085 microfarad per mile. The wires are wrapped with specially prepared paper, which forms the only insulation, and are twisted in pairs and drawn into a tube of lead slightly alloyed with tin. The tube is hermetically sealed at the ends to prevent access of moisture, and sometimes contains as many as 200 pairs of

contact between the two springs, S¹ S², which are normally apart. S¹ is attached to a movable piece, P¹, kept in the break-circuit position by a strong spring. The coin, C, drops between P¹ and another movable piece, P², actuated by the push-button, B. The coin when dropped rests in the first position and forms a bridge between P¹ and P². The thrust of the push-button brings S¹ and S² together, as shown in the second position, and the release allows the coin to drop into the till. The firm has devoted a good deal of attention and ingenuity to supplementing domestic bells, both mechanical and electric, by telephones, so that the servants may not

only be called but spoken to, and thus saved a journey of enquiry. Fig. 6 shows the device as applied to ordinary mechanical bell-pulls. The rosette is removed from the pull and replaced by an ebonite disc, which supports a magneto watch telephone in spring clips. A similar instrument is provided in the kitchen, and twin wires are run through the house, with branches to each bell-pull. This combination of the old and new certainly possesses the merits of cheapness and simplicity, and there is no reason why it should not work satisfactorily. The same idea is applied to an existing installation of electric bells, the telephone being carried on a clutch-plate and fixed to the wall alongside the usual push-button. In this case the electric bell wires serve likewise for the telephone.

AN EXAMPLE OF CHURCH LIGHTING.

A "dim religious light" may be poetic, it is certainly not pleasant. Modern worshippers, whatever their denomination, want to be able to see, and, may we add, be seen. To light a church or chapel brilliantly by means of gas means also introducing into that church or chapel the most certain cause of headache and *malaise*. It is necessary to light the gas some time before service. Occasionally this is done hours before in order to warm the church, the result being an atmosphere which quickly induces a "used-up" sensation. The building is a lethal chamber on a large scale, only needing to be hermetically sealed to produce fatal results. Clergymen who use gas in this way should not complain if a certain drowsiness is noticeable among the members of their congregation by the time the sermon is reached. Human nature cannot long hold out against the effects of asphyxiation even when the process is slow, and not commonly understood as such. Or take another point of view. As we have said, people want plenty of light nowadays. With gas this means the production of an enormous quantity of by-products—not usually known by this term—which promptly attack, and in a comparatively short space of time work havoc with the decoration of a church. Many thousands of pounds have been spent on the decoration of our cathedrals and churches which might almost as well have been thrown into the sea, for in close proximity to costly gilding and painting are

The Mediæval Court at the Palace fitted up as a Sanctuary—Messrs. Benham and Froud's exhibit.

long rows of gas jets emitting that which will effectually ruin both. By-and-by no doubt the beauties of our ecclesiastical architecture will be illuminated by nothing but the electric light, and people will wonder how a bygone generation could have been such lunatics as to employ gas. This movement in the right direction will, we hope, receive a stimulus from an example of church lighting and decoration to be found at the Exhibition. Here the energetic firm of **Messrs. Benham and Froud,** of Chandos-street, Charing Cross, in conjunction with **Messrs. Frank Smith and Sons,** of Southampton-street, Strand, have fitted up a sanctuary in a way which does them credit. Originally Messrs. Benham and Froud intended to erect a special stand for the purpose. It was suggested to them, however, by the Crystal Palace authorities that the Mediæval Court there provided them with just what they wanted ready to hand, and would give them a far better opportunity for carrying out their design than could be obtained by the erection of a stand howsoever cleverly constructed. The firm in question readily

adopted the suggestion, and the result is in every way satisfactory. In passing, we may remark that the various courts, representing different styles of architecture, are well worthy of a careful study on the part of visitors to the Exhibition. The plaster reproductions have been so well done as to almost deceive the eye, whilst the collection includes examples from some of the most noted buildings in this country and abroad. But to return to the Mediæval Court, which readers will find to the right of the Edison-Swan exhibit looking north. The sanctuary includes some very beautiful examples of church embroidery and metal work. The altar is furnished with six massive brass candlesticks and cross, with medallions of the four evangelists in oxidised silver. The embroidered dossal hangings and altar cloth have been supplied by Messrs. Frank Smith and Sons, and are handsome specimens of this class of ecclesiastical fittings. A brass eagle lectern of fine workmanship stands to the left of the altar steps. Lecterns of the same pattern have been supplied to Glasgow Cathedral, St. Stephen's, Westminster, and other churches. A specimen panel in patent metal mosaic, with the figure of St. Luke in hand repoussé work, should attract some attention. It is made by a new method of imitating ordinary mosaic in metals. Those employed in this case are copper, brass, and nickel, and the effect is very good. From the roof depends a very fine 12-light electric corona in brass, and also two other coronas in wrought iron. Two specimen standards carrying nine lights each, for use in a chancel, are also shown. The leads to these lights are run on a method introduced and fitted up by **Messrs. Smythe and Payne,** of Albany-buildings, Victoria-street. The system consists of concentric copper tubes insulated from each other and encased in fireproof material, the whole being sheathed in brass. This brass sheathing gives the leads an appearance in complete harmony with the ordinary church fittings, and they do not obtrude themselves on the eye. The *tout ensemble* of this exhibit is very fine, and we congratulate Messrs. Benham and Froud on the happy result of their efforts, which will, we think, cause many a dignitary of the Church to covet the electric light.

BUFFALO MEETING OF THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

The fifteenth annual meeting of the American National Electric Light Association was held at Buffalo on February 24. The abstracts of the papers just come to hand show that a large proportion of practical and interesting papers were read. Some of these dealt more particularly with American practice, but of the others the following abstract gives the principal points dealt with and the conclusions at which their authors arrived. The first, that on "Alternate-Current Motors," by Mr. Wm. Stanley, jun., being extremely important, we give in full elsewhere.

THE RELATION OF SIZE AND EFFICIENCY IN TRANSFORMERS.

A paper which comes very *apropos* at the present moment is that with the above title, by Mr. L. B. Stilwell. The designer of a transformer, says Mr. Stilwell, has two alternate paths: he may aim at high efficiency at light loads, or he may aim at large output with little weight, in which case he may endanger the insulation. The best transformer is not necessarily that which has the least loss in magnetising current, nor that which regulates most closely, nor that which is lightest, nor yet that which does not increase in temperature, but the one that best embodies all these properties. A commercial five-light transformer cannot be made to lose less than 20 watts, but a 10-light transformer can be made to lose not more than 25 watts. If the capacities are 250 and 500 watts, the losses are respectively 8 and 5 per cent. A 20-light transformer can be made with an iron loss of 30 watts, and for 40 lights at a loss of 45 watts—respectively a loss of 3 and 2·25 per cent. A 40-light transformer substituted for two 20-lighters will reduce the loss from 3 to 2·5 per cent., and more if substituted for smaller sizes. Transformers for 100 lights can be made with a loss which does not exceed 1·7 per cent., but beyond this size improvement is difficult. The loss due to copper resistance is usually about 2 per cent., not varying materially in the various sizes. Assuming the copper loss constant, the following table represents the average proportionality of losses. Actual tests show results as good as, or even better than this:

Capacity in 16-c.p. lamps.	Loss in iron.	Loss in copper.	Efficiency at full load.
5	8 per cent.	2 per cent.	90 per cent.
10	5 ,,	2 ,,	93 ,,
20	3 ,,	2 ,,	95 ,,
30	2·5 ,,	2 ,,	95·5 ,,
40	2·3 ,,	2 ,,	95·7 ,,
60	2·1 ,,	2 ,,	95·9 ,,
80	1·9 ,,	2 ,,	96·1 ,,
100	1·7 ,,	2 ,,	96·3 ,,
300	1·5 ,,	2 ,,	96·5 ,,

It will be seen that for sizes less than 20 lights the falling off in efficiency is very great, while above that the gain is less marked. The significance can be better realised in the following comparisons, expressing the losses in lamps and taking a total capacity of 1,200 lamps of 16 c.p.

Transformers.		Loss in lamps at no load.	Loss in lamps at full load.
240	5-light capacity	96	120
120	10 ,,	60	80
60	20 ,,	36	60
40	30 ,,	30	54
30	40 ,,	27·6	51·6
20	60 ,,	25·2	49·2
15	80 ,,	22·8	46·8
12	100 ,,	20·4	44·4
4	300 ,,	18	42

These figures show plainly that for any number of lamps up to 100 it is better to use one transformer rather than a number of smaller transformers; above 100 the gain is not so marked.

In the discussion, Mr. Wm. Stanley, jun., remarked that the most efficient transformer would be, he believed, the hottest—that is, build a coil and get in it as much iron as possible. Prof. Elihu Thomson thought a transformer would run best if the iron were run as hot and the copper as cool as possible. If the core were enclosed and the copper ventilated, we should obtain the ideal transformer. Mr. Stanley questioned if the transformer of the future would have inflammable material in it at all; he was making transformers with the copper embedded in a solid dielectric, the section resembling that of a well-constructed cable.

TRANSMISSION OF ELECTRIC ENERGY.

Mr. H. Ward Leonard read a paper on the "Transmission of Electric Energy by Alternating Currents, and its Utilisation by Continuous Currents." He made the claim that economical transmission of power over long distances necessitated the use of both alternate and continuous currents. The plant at the receiving end should be installed exactly as if to be driven by a steam engine, but should instead be coupled to a synchronous alternate-current motor, which should be started by a small storage battery or other means. If one comprehensive plant were installed, he believed an enormous development of this system would immediately take place.

HIGH-TENSION CURRENTS UNDERGROUND.

Mr. E. A. Leslie has an extremely practical paper on the underground conduits in New York for high-tension conductors. The "trunk" ducts are of iron pipe, mostly 3in. diameter, running to manholes 275ft. apart. Over the trunk ducts are two to four distributing ducts, with four-way manholes, 50ft. apart. The conduits are owned by the Subway Company. The companies Mr. Leslie is connected with use cables insulated with rubber compound. A copy of the specification is given of these cables. The manner of drawing in is explained. The proper jointing is regarded as a matter of paramount importance—unless made by an experienced man the joint shows nearly always less insulation than the cable. The following rule of the Subway Company, at one time impossible of compliance, is extolled by Mr. Leslie as the preventive of after-loss:

Section 4.—*Electromotive Force.*—All conductors drawn into and operated in the conduit, and intended to convey currents of an electromotive force exceeding 100 volts, shall have at the temperature of 75deg. F., an initial resistance of not less than 15 megohms per mile per 100 volts electromotive force of current in

the circuit. Whenever the resistance of a conductor, as aforesaid, shall prove to be less than five megohms per mile per 100 volts, the use of that conductor shall at once cease, unless the actual electromotive force in its circuit be so reduced as to re-establish the foregoing ratio.

This means that for a 1,000-volt circuit an insulation resistance before the current is turned on of 150 megohms per mile is required, and for 3,000 or 4,000 volts, 450 and 600 megohms. These seem difficult conditions, but it is rare that the tests on the New York cables do not show three to four times this resistance, and these have remained nearly, if not quite, as high for two or three years. Examples were given. Tests are made every week with a portable reflecting galvanometer. The insulation, including arc lamps or converters, usually falls below this standard, but unless less than one megohm per mile, the condition is accepted. Lower than this, lamp or converter tests are made and the defect removed. The cost of house connections is very high—appalling, to a man of overhead experience only. The cost of connections to city lamp-posts, including pipe, cable, and labour, is 110dols., say, £22, per post. Mr. Leslie goes into the financial aspect of the hire of subway ducts. The rental is 1,000dols. for distributing ducts, and 550dols. up to 900dols. for trunk ducts. The cost may be judged from the statement that the total rental of ducts exceeds the total for coal, oil, waste, and the salaries of chief engineer, engineers, firemen, coal handlers, and oilmen employed in the machinery department. He sums up the question thus: The underground system of lighting is perfectly possible on an extended scale; it is less liable to interruptions than the overhead system; it is less dangerous to life; its cost is enormously greater; it is very cumbersome, and lacks flexibility; and its cost precludes its extension to sparsely-populated districts, which must either be supplied by overhead wires or abandoned.

TRANSMISSION OF POWER FROM NIAGARA.

Mr. Carl Hering read a paper on the "Transmission of Power, with Special Reference to the Frankfort Plant." The paper first described the apparatus used on the Lauffen-Frankfort transmission, and gave a lucid explanation of the three-phase current. Mr. Hering closed his lecture with the following passage:

"The Oerlikon Company gives the following figures regarding the cost of the plant: Assuming the 300 h.p. is developed at Lauffen, and that all the energy received in Frankfort was converted into light, the cost of the plant per effective horse-power measured at the terminals of the lamp will be about £56, of which £47 is for the line alone. These figures appear high, but it must not be forgotten that in this particular plant there were conditions which would not be likely to occur in practice—namely, relatively small power on the one hand, and exceedingly great distance on the other, both of which factors naturally increase the cost per horse-power. It may be of interest to state that Mr. Dobrowolsky, of the Berlin firm, states that he would be willing to bid on the contract to transmit 1,000 h.p. or 5,000 h.p. from Niagara to Chicago, a distance of about 500 miles. He proposes to use 40,000 to 50,000 volts, and claims that an efficiency of 60 to 75 per cent. could be obtained without difficulty."

He also adds the following: "I received this morning a letter from the Zurich people, the Oerlikon Company, who you may know have put in a bid for the transmission of power from Niagara Falls to Buffalo. They propose that the current generated at the Falls is to be such that both motors and lamps—arc lamps as well as incandescent lamps—shall be used. That is, the current shall be fit for motors, arc and incandescent lamps. They say the Drehstrom—that is, the rotary current—is at present, and will be for a long time to come, the only practical form of current to run large motors of a fair efficiency. They propose to use 50 periods in place of 40, which were used at Lauffen, because they say that 40 is too low to run arc lamps. Fifty is said to be the lowest at which arc lamps will run satisfactorily. The generating station would be composed of units of 5,000 h.p. each. The dynamos must therefore be of 5,000 h.p. According to the wishes of the turbine *designers*, the number of revolutions has been fixed at 250 per minute. The diameter of the armatures has been fixed at 3½ metres—that is, about 10ft. The armature is to be drum wound. I suppose that means the drum winding on the surface of the cylinder—that is, not across the ends, as we usually wind drum armatures in America, but wound as they very often do in European multipolar machines. The currents are to be 2,000 amperes in each of the three circuits, and the voltage 600 to 700. It has been found advantageous to revolve the armature instead of the magnetic field, in order to have a minimum weight on the vertical shafts. The weight on one of those shafts, by the way, is something very great. The shafts are 20ft. long, and the weight of the shafts together with that of the armature and turbine is a very great weight, and must therefore be considered. The generators will have 24 poles. They will be separately excited. The efficiency will be in the neighbourhood of 96 per cent.—that is, the efficiency of the dynamo, including exciting power. There will be two transformers, as it was not found practical to build a single transformer of 5,000 h.p. The transformers will be artificially ventilated, and only the high-pressure coils will be placed in oil. These transformers will raise the potential to 25,000 volts. 'This,' they say, 'is no longer to be looked upon as an experiment. The cost of the line will be about 100,000f.—(that is, £4,000)—an almost trifling part of the whole for the total distance. It is a simple pair of copper wires—that is, three pair of copper wires on poles, the cheapest kind of a line. As to the line, we propose not to carry any more than one or two units of 5,000 h.p. on one line of poles for a number of reasons. A 5,000 h.p. or 10,000 h.p. can be conducted on wooden poles at a very moderate initial cost of plant. The lines would terminate in one or more step-down transformer stations that would supply current of 1,800 to 2,000 volts for municipal and street lighting in the shape of alternating currents to be transformed down to the suitable lampvoltage, as is the case in the present transformer systems. The cost of the electrical part of the proposed plant, including the generators, exciters, and transformers at both ends of the line, would be about 180,000dols. (£36,000) for each unit of 5,000 h.p. with an efficiency of 84 per cent. at the low-pressure terminals of the secondary transformers. This reduces to 36dols. (£7. 5s.) per horse-power. The cost of the line is about 4dols. (16s. 8d.) per horse-power, which is about 10 per cent. of the whole.'"

At the close of the lecture Mr. Hering showed a number of magic lantern slides illustrative of the Frankfort-Lauffen apparatus, line, exhibition, etc.

Prof. Elihu Thomson expressed himself in favour of the three-phase system, with underground wires in oil, which could be run up to 100,000 volts.

Mr. L. B. Stilwell preferred a two-phase system for combination work, where motors and lights were required.

Mr. C. S. Bradley spoke of his pioneer work in the rotary-current system, stating his preference for three-phase currents.

Mr. Stanley said it would be interesting to members to know that a 15,000-volt line was working at Pittsfield using 20 h.p. The striking distance is twice as great at this than at 10,000 volts. Within an inch or two of the ground there is a miniature aurora borealis, and the current will go right through a dry deal board without affecting the current in the slightest. They had undertaken a contract to transmit 400 h.p. a distance of 28 miles. The Dobrowolsky 2-h.p. motor, he was informed, required 4,200 watts to run at no load, and 14,000 watts (10 times its rated capacity) at full load. Of the current apparently applied, 14,000 watts, only 1,500 watts are actually useful. The Tesla motor uses ·6 of its full load current to run empty, and ·7 of this is usefully applied; so that about ·7 × ·6 × the total energy is required to run the motor. The synchronous motor has one serious defect, that if overloaded much it is liable to burn up.

BOILER FIRING.

"How to Fire a Boiler" was the title of a paper by Mr. R. Hammond. Amongst other things, he said: "Experiment has proved that bituminous coal requires 150 cubic feet of air per pound of coal for good consumption. An excess of air results in a waste of heat which is carried into

the flues and chimneys, and often a greater loss than the insufficiency of supply of air to produce good combustion.

"In my experience for steam plant boilers carrying 80lb. to 160lb. of steam, I find that at least 20lb. of bituminous coal should be burned per square foot of grate per hour, and the air spaces of the grates should not be less than 50 per cent. of the grate area; if the grate surface is so large that only 10lb. of coal is consumed, it would be more economical to reduce the grate surface and burn not less than 20lb. with good draught, thus securing a good combustion. The same weight of coal burned on a large grate would not be as economical, on account of the low temperature; the temperature of the furnaces should not be less than 3,500deg., and the ratio of the draught area through the tubes or flues should not be less than one-sixth nor more than one-fourth of the grate surface, and the proportion of the grate surface should be at least as 35 to 1. The steam users should see to it that all parts of their boilers and settings should be of equally as good proportions for strength and economy as their engines; employ good, intelligent firemen as well as engineers, and see that both produce good indicator cards." It was insisted that intelligent firemen should be engaged and well paid; this would result in a reduction in the pounds of coal per lamp lighted. Judge ARMSTRONG in the discussion suggested that a "bureau of firing" should be organised.

OVERHEAD CONSTRUCTION.

Mr. E. F. PECK, in a paper on overhead construction, dealt with the practical side of this problem—the building of wire-towers and the running of overhead circuits. Referring to the poles, he said his attention had been recently called to the Haskins process, which seems to be highly successful. This process consists in the placing of timber in an air-tight retort, and subjecting it to the heavy pressure of superheated air, which permeates the whole section, thereby accomplishing the same result as a charring process, without altering any of the chemical properties of the wood. Joints should be soldered on all electric light circuits. He had found that wrapping a joint with tinfoil and then covering with a good rubber tape make a good substitute for soldering, easily applied, for temporary work.

The report of the Committee on Underground Conduits and Wires was read, describing various American and English systems. It was agreed the experience has been too short to give a fair comparison of cost between aerial and underground conductors.

The Committee on Safe Wiring recommended that the rules should be amended by prohibiting inside conductors being laid in plaster or cement in a room where inflammable gases are used; that the lamp and socket be enclosed in a vapour-light globe; that interior conduits must not be made of any substance liable to be injured by plaster or cement.

The report of the World's Fair Committee was also read.

Papers were also read, entitled:

"Electric Lighting from a Financial Standpoint," by Mr. Erastus Wiman.

"Transmission of Power," a mathematical paper dealing with the transmission of power from the consumer's point of view.

"From the Tannery to the Dynamo," by Mr. Charles A. Schieren, being the natural history of a belt.

"Construction, Safety, and Operation of Switchboards," by Mr. M. C. Sullivan.

"Franchises for Quasi-Public Corporations," by Mr. Allen R. Foote.

"The Underground Construction of the Buffalo Railway Company," by Mr. J. B. Craven.

Electric Organ.—The Vicar of Meanwood Church, Leeds, has accepted the tender of Messrs. Abbott and Smith, of Bradford, for a new organ controlled electrically. The keyboard will be detachable, enabling the performer to play from any part of the church. The organ will contain 29 stops and 1,385 pipes, and will be blown by a hydraulic engine.

WALSALL ELECTRIC LIGHTING.

PARTICULARS OF REQUIREMENTS AND STATEMENT OF INFORMATION TO BE FURNISHED WITH TENDERS.

The area proposed to be supplied with the electric light is coloured pink upon the plan. The length of the respective streets comprised in such area is as follows:

				Feet.
Wolverhampton-street	A	to	B	1,600
Park-street	B	,,	C	948
Bradford street to Vicarage-place	C	,,	D	1,500
Vicarage-place to George-street	D	,,	E	946
George-street to High-street	E	,,	F	810
Digbeth and High-street	C	,,	G	1,053
Goodall-street	H	,,	I	653
Bridge-street (Upper)	I	,,	K	615
Bridge-street (Lower)	K	,,	N	427
Leicester-street	K	,,	L	330
Darwall street	L	,,	M	229
The Bridge	C	,,	N	138
The Bridge	M	,,	N	181
Total				9,430

It is suggested, with a view to economy, that the generating station may be placed at the gas works in Wolverhampton-street, which are the property of the Corporation, but the contractors are at liberty to suggest any other site that may appear to them to be more suitable, giving their reasons for so doing. A plant is required sufficient for the demands of 3,000 60-watt lamps wired, and regard should be given to the fact that power may also be required for small motors, and reasonable provision should be made for this and also for future extensions. The works comprised in the tender are to be divided into four sections as follows:

BUILDINGS.

Section I.—The buildings are not desired to be of a highly ornamental character, but must be plain and good in all respects. Plans and details of such buildings as may be necessary for boilers, engines, and dynamos must be supplied, room being left for an extension of plant in each section.

BOILERS AND ENGINES.

Section II.—Details of these are to be given and a guarantee as to evaporating power with the ordinary coal of the district. The canal company's water, which may be used, is not good. Full particulars of these to be supplied, and a guarantee of horse-power per stated amount of steam at average working load. State make, speed, and guaranteed insulation. State the amount of coal that will be used per electrical horse-power generating at quarter, half, and full load. Give full particulars of all instruments to be supplied, and what switching apparatus would be provided.

STORAGE.

Section III.—If storage is included give particulars as to make, maximum discharge, and capacity, and specify particulars, including the necessary arrangements for switching and regulating.

MAINS.

Section IV.—Supply full particulars of these, stating sectional area, how insulated and guaranteed insulation, resistance per mile when laid. Give particulars of proposed system of laying, also of joint and test boxes. Separate prices must be given in the tender for each section. The whole of the work to be carried out in accordance with the provisions of the Walsall electric lighting order of 1890, and to the satisfaction of the Council and their electrical engineer for the time being. A price must also be stated in the tender for running for six months after completion, contractors paying all expenses excepting fuel and water.

Cost of Carbons.—Mr. James Blake, managing director of the Fareham Electric Light Company, states that the cost of their arc lights last year, on a basis of 2,000 hours, did not amount to £2 per lamp for carbons, and the total cost of carbons and attendance did not exceed £2. 10s. per lamp.

CONTENTS.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months		6 months		12 month
United Kingdom	3s. 3d.	...	6s. 6d.	...	13s. 0d.
Within the Postal Union	4s. 4d.	...	8s. 8d	...	17s. 4d
Other Places	4s. 10d.	...	9s. 8d.	..	19s. 6d.

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vols. I. to VIII. inclusive, new series, of "The Electrical Engineer" *are now ready, and can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers for binding can be obtained, price 2s*

IMPORTANT.

RE BRISTOL ELECTRIC LIGHTING ADVERTISEMENT.

After our advertisement pages had been printed we received certain corrections, which are to the following effect: line 8 read, "steam dynamos with *Willans engines*"; line 9 read, "*Lancashire* boilers"; line 14, after boilers, insert "*and boiler makers only will be permitted to tender*"; after 25th inst., line 19, insert "*on payment of £3 for each specification, which will be returned on receipt of a bona fide tender from parties entitled to tender.*"

OIL INSULATION.

The time of oil as an insulator is coming upon us. So much may be judged from the signs of the times. The use of oil, especially heavy rosin oil, on electrical work has been long advocated by us, and we have devoted many articles to the description of the process of running cables in oil brought prominently forward by the late Mr. David Brooks, the system now in the hands of Messrs. Johnson and Phillips. The demonstrations by Brooks have, no doubt, had their effect, but, practicable as he showed the use of oil insulation to be, the employment of it on any large commercial scale has hung fire. It has required the work of Ferranti and of Tesla to draw the attention of the world to the advantages of very high potentials, and in these cases the great advantages of oil insulation become apparent. Necessity is, we all know, the mother of invention; and when circumstances require a process to be discovered, man seeks, and always finds. Sometimes, however, he finds it too early, and no use can be made of his researches. This has been the case with oil insulation, for it appears the advantages of this method of insulating cables were perfectly well known, and methods for its use even patented, by one of the greatest and one of the most modest of our present electricians, Prof. Hughes, who already, in 1859—over thirty years ago—as stated in his paper given last week, had fully tested and recognised the advantages, not only of oil, but of rosin oil for insulating purposes. Many electrical engineers who had never before perhaps given the matter more than a moment's thought must have recognised, after witnessing Tesla's experiments with his high-tension transformers in oil and Prof. Hughes's simple but highly interesting experiments with faulty wires in a tube of oil, that the high insulating power, together with the absolute certainty and ease of repair of fault, will stand them in the greatest stead in the coming problems of high-tension current transmission. Mr. Ferranti has long recognised its value, and his junction and transformer boxes have been built, we believe, for some years to use oil. Brooks himself laid and worked telegraph cables in England many years ago, and several installations have since been fitted with oil-insulated cables—amongst others at Keswick. The statements and experiments of Prof. Hughes will, of course, turn the attention of cable manufacturers to the more extended use of oil, and many who have credited Brooks with absolute priority in this question will now feel free to use the system. It is doubtful, however, whether this matter of priority really affects the question very much after all, for a principle cannot itself be patented, and therefore anyone is to this extent at liberty to use oil—and rosin oil. The use

of oil has, however, its limitations and its regulations, and these must in practice be strictly complied with. Any patentable apparatus or methods may therefore to this extent still hold good. Even were this not the case, those who have tried and worked the method must necessarily be those who know most about it, and therefore we can see that the eulogy of oil by Prof. Hughes and by Mr. Tesla will redound to the advantage of the firm who have been pioneers in this system. The extended knowledge and recognition of the advantages of oil as an insulator cannot but cause its increased application in the future to high-tension conductors generally, and may materially aid in the solution of that most difficult problem, the thorough control of high-tension current. For such a consummation all the names which are associated with this important investigation will deserve the fullest credit—a great part of the credit, as in so many other electrical inventions, devolving upon the honoured name of Prof. Hughes.

ALTERNATE-CURRENT MOTORS.

One of the most interesting and suggestive papers we have seen recently is that by Mr. Wm. Stanley, jun., on "Alternate-Current Motors," read before the Buffalo meeting of the National Electric Light Association, which we give in full. Suggestive as it undoubtedly is, most of the statements made dealing with the manufacture of a practical alternate-current motor are of processes which "cannot be disclosed at present." The author seems to have obtained some very definite results, his idea being to produce a motor—a "condenser" motor—which will run on an ordinary alternate-current circuit. The field winding is connected in series with a condenser. The armature, though wound specially, is substantially the same as a continuous-current armature, but is surrounded with copper bands, whose function is to take oppositely-induced currents (the loss being small), these currents preventing any magnetising effect or loss by hysteresis. The motor uses currents differing in phase, but obtained from an ordinary alternate-current circuit. Mr. Stanley and Mr. Kelly have discovered an entirely novel and complete solution to the problem of splitting a current from a single transformer into two currents varying in phase to any degree desired. The method of doing this is to be published shortly. Tesla motors could then be run on any ordinary alternate-current circuit. "The Tesla motor for the past five years," says Mr. Stanley, "has been waiting for one thing only to develop it—a current splitter—and we have found it." English electrical engineers will be glad to learn this, and alternate-current supply companies will draw breath with relief. The system, besides the special winding of the armature, embodies the use of condensers, and the most serious question was to find a suitable condenser. Here, again, we must take Mr. Stanley on trust. He has tried glass, which breaks eventually even at 1,000 volts; vulcanite is unsuitable from the metal chips or other impurities always present. Messrs. Stanley and Kelly have succeeded in producing what they term "films" from ·003 to ·006 of an inch thick that withstand with certainty 1,000 to 3,000 volts; condensers made with these films do not heat, show no residual charge, are cheap to manufacture, and, it is believed, do not deteriorate. As before, the processes of manufacture cannot be disclosed at present. The condenser motors start at full torque, run to a definite speed, and behave like continuous-current motors under load. Self-induction is almost entirely eliminated, and the efficiency, though low (40 per cent.) for small motors, reaches 75 per cent. for 2 to 5 h.p. motors, and will be still higher for larger sizes. Mr. Stanley may well be congratulated on his investigation, fuller particulars of which will be awaited with great interest.

TAUNTON.

It is well known to most of our readers that all parliamentary action relating to electric light contemplates the possibility of the local authority doing the work itself, or at some period after the work has been done by others, taking it over as a going concern. The example of Taunton is perhaps not exactly analogous to the taking over of an installation from the concessionaire of a provisional order or license, but it is a case where a central station has been equipped and carried on by private enterprise, and where now the local authority is considering the advisability of taking it over. Our opinions as to the local authorities doing the work themselves are well known, and unfortunately, as some consider, are not accepted by the mass of the industry. We have always contended that the best way to carry out central station work is under the local authority, and not by private companies. The next best way is by means of a local company, and this generally finds favour. The local authority possesses great advantages, which should lead to diminution of initial cost and of cost of maintenance. Sanitary, water supply, and lighting matters are just those matters with which the local authority should deal, because each one affects the general welfare, and the aim should be to benefit everybody, and not contribute to the gain of individuals. At any rate, the fact remains that local action in electric lighting matters is contemplated. Taunton was, so to speak, the first town to really patronise electric lighting; it seems to be the first town to consider the taking over of a going concern. The mode of procedure will therefore be interesting to all who in the future have to follow in the same direction, hence we feel no hesitation in giving verbatim the report of the committee to be considered at the next Council meeting. It will be seen that the committee has been in communication with the Board of Trade, and has obtained from the borough surveyor an exhaustive estimate upon which to base conclusions.

Calcutta.—Sanction has been granted to the engineer's estimate for 11,553 rupees and 1,393 rupees for a proposed electric light station adjoining the Halliday-street pumping station at Calcutta.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

SWITCHES AND THE CHATHAM ACCIDENT.

SIR,—I was pleased to read your article on the Chatham accident. You are quite right; the high-tension current should never be led into the house, then there would be no necessity for a switch to cut it off. A high-tension switch cannot be made on a small scale to be safe, and if made large enough, and it must be double-pole, the cost would be a serious item in a small installation. As you say, many of the switches are bad—condemnably is scarcely the word; cut off the "con" and you are nearer to it. A high-tension switch should be built on broader lines: the contacts should be further apart, the opening of it so far that the arc cannot follow, and the handle more like a railway signalman's lever, only made of wood; a man could then pull off a 2,000-volt switch without fear of burning his hands. Designers of these switches should study the arrangement on the Thomson-Houston switchboard at the Crystal Palace.—Yours, etc., W.

SIEMENS CABLE TRANSFORMERS.

SIR,—As some mention has been made recently of the Siemens cable transformer in your journal, it may be of interest to know that on April 3, 1886, I patented (No. 175,242) in France, a similar transformer, consisting of a stranded iron rope surrounded with two separate windings of copper wire.

I should be obliged if you can find space for the insertion of this letter in your columns.—Yours, etc.,

Baden, March 7, 1892. C. E. L. BROWN.

ASSOCIATION OF MUNICIPAL ENGINEERS.

A meeting of the Incorporated Association of Municipal and County Engineers was held on Friday and Saturday last. A paper was read by Mr. William Weaver, M.I.C.E., on Saturday before the members meeting in the Kensington Town Hall dealing exhaustively with the vestry work of Kensington, from which we extract the following paragraphs dealing with electric lighting:

"The whole of Kensington is within the area supplied by the Gas Light and Coke Company, and the author gave details as to number of lamps and cost. With regard to the Electric Lighting Act, the author advised the Vestry to apply for a provisional order and go in for the work themselves, a course since adopted by the Vestry of St. Pancras. Looking to the enormous amount which would have to be raised, and the probable discontent of residents in districts outside the first areas lighted, the Vestry deemed it preferable to divide the parish into six areas, which have been allotted to five companies—viz.: London Electric Supply Corporation, Limited; Notting Hill Electric Lighting Company, Limited; Kensington and Knightsbridge Electric Lighting Company, Limited; Chelse Electricity Supply Company, Limited; and the House-to-House Electric Light Supply Company, Limited. The last-mentioned company undertakes the lighting of two areas. The system of supply adopted by the whole of the companies (except the House-to-House Company) is arranged on the low-tension system. The House-to-House Company's system is an alternating-current, transformer high-pressure supply, with high-pressure service lines from distributing mains, and transformers on consumers' premises, reducing the current to low tension. The provisional order granted to this company contains a condition, that so soon as the amount of supply in the district appears to warrant it, the company may be called upon by the Board of Trade to establish distributing stations and lay distributing mains worked at a low pressure. About 15 miles of roads and footpaths have been opened up for the purpose of laying electric mains in the parish. In some cases the conductors have been laid in brick or concrete culverts; in other places, *Callender bitumen tubes* or iron pipes have been used. In laying the mains numerous difficulties have to be surmounted—in fact, in some streets it has been a matter of extreme difficulty to find space in which to lay the mains. The author is strongly of opinion that all main roads, at any rate, should have a subway for the reception of mains, etc. If such subway was built simultaneously with the construction or reconstruction of the sewer, the additional cost would not be great; there would be no extra excavation, the additional cost would be for the brickwork only, plus the necessitated extra surplus earth to remove, and if the excavation was in sand, such surplus earth would form a credit. Stoneware pipes for the reception of the gas and water services and electric wires could be laid from subway to vaults, and if these pipes were laid in the drain trenches, the cost of the stoneware pipes would be the only extra cost beyond subway. The author is of opinion that if the cost of such subway works were defrayed by a loan spread over 50 years, the various companies could be charged a rent which it would be economical for them to pay, and sufficient to return a profit on the outlay. At the same time the appearance of the roads and footpaths would be vastly improved, and the comfort and safety of the public enhanced."

"The question of destructor or no destructor was made an election test, and by a considerable majority the proposal to erect a destructor was condemned, and subsequently the utilisation scheme adopted. The author's reports to the Vestry were in favour of the erection of a destructor for consuming the non-saleable part of the house refuse, and the employment of the waste heat in working machinery: first, for the washing of the refuse from flint and macadam roads; and secondly, for the generation of electricity. The electric current generated could be used for street lighting or for propelling the dust-carts. The latter would effect a saving of about a moiety of the manual labour now employed, and would of course abolish the horses now employed chiefly in standing about with their nose-bags on to keep them quiet."

VISITS.

The first visit of the association was on Friday evening to the Crystal Palace Electrical Exhibition, and in order to keep all the visits under one head we refer to it here. The members began their inspection of the Exhibition about 5.30, in two sections, under the guidance of Mr. Crompton's engineer and Mr. H. Swan, assistant editor of the *Electrical Engineer*. A visit was first paid to the Machinery Department, where the large central station plant of Messrs. Crompton, on the low-tension system with accumulators, was inspected. The high-tension alternating-current system of the Brush Electrical Company was next visited, and the working of the large Mordey alternator driven by rope gearing as used at the Bath and City of London stations, was watched with great interest. Messrs. Siemens's large direct-current low-tension plant, as used at the Naval Exhibition, and destined for the new station of the St. James's Company, came in for a share of admiration, though not running. Messrs. Davey-Paxman's engine, driving the large Kapp dynamo constructed by Messrs. Johnson and Phillips, was regarded as another excellent example of central station work; and the permanent engine and dynamos of the Gulcher Company, which light the Palace itself, was also visited. The motor-transformers, as used by Messrs. J. E. H. Gordon and Co., for supplying current from the Sydenham station to the exhibitors, was also inspected. A great deal of interest was manifested in the gas engines, especially those of Crossley, Wells, and the Stockport Company. An exhibit which all wished to see was the high-tension experiments of Messrs. Siemens Bros. Here illustrations were shown of the behaviour of direct and alternating currents, and the musical notes of the alternating current were heard in a telephone; but the most interest was aroused when the 50,000-volt current was turned on in an overpowering, spluttering, and creeping shower of lightning flashes over a 2ft. sheet of glass. The strength of the current was illustrated by lighting a row of 500 lamps in series arranged upon a single wire. Music from Manchester and the Lyric Theatre was next indulged in at the Telephone-room, and the huge screen of Edison-Swan lamps was seen alight. The illuminated waterfall and the kiosks full of lighted

lamps were most fairylike in their effect; the flashing of Crompton's projector illustrated the search light; and the Crompton crane, lifting, travelling, and slewing at the same time, was witnessed with much interest. The Brush Company's sets of combined engines and dynamos came in for much admiration, and their quartz-crushing machine was seen in operation. The Siemens passenger and dinner lifts were inspected, and then the visitors wandered through the electrically-lighted furnished rooms in the gallery—exhibited by Messrs. Wallace, Allen and Manooch, Godfrey Giles, H. and J. Cooper, Rashleigh Phipps and Dawson, and Messrs. Faraday and Sons.

The members on Saturday visited, among other places of interest, the West Brompton electric lighting station of the House-to-House Electric Supply Company. Much interest was taken in electric plant at this meeting from the pressing importance of the subject. Mr. Hammond received the visitors personally, and explained the system used, of slow-moving engines driving alternators, adopted as a standard type of central station, and employed at Dublin and Madrid. The working of the alternating dynamos and the switching apparatus was explained, and attention was drawn to the fact that one dynamo had run 665¾ hours continuously without breakdown.

The last visit of the day was to the Kensington and Knightsbridge electric lighting station, a visit which was greatly appreciated both from the interest of the station itself and the courtesy of the company's engineer, who very clearly explained the working. They had, he said, a number of Willans engines coupled direct to Crompton dynamos; these could be started at a few minutes' notice to supply the current. The low-tension current was used on the three-wire system, with accumulators. The switching was done upon a large regulating switchboard upon indication of pressure on the voltmeters connected to wires from the distant points. The accumulator-room contained two sets of large lead-plate accumulators, Crompton-Howell system, each set sufficient to supply 3,000 lamps for an hour. Two further sets were placed in a sub-station at some distance. The cost of manufacture was about 3d. to 3½d. per unit, which with general charges amounted to 5d. or 5½d. The price charged was 8d. per unit, and they sold all but 10 per cent. of that they manufactured. Lamps could be supplied within a radius of 1½ miles on this system without sub-stations. There was no danger whatever at any part of the circuit. The members afterwards dined together at the Holborn Restaurant.

THE BEHAVIOUR OF INSULATING MATERIALS UNDER THE ACTION OF HIGH-POTENTIAL DIFFERENCES.*

BY H. BLECKLY BOURNE AND W. FOX BOURNE.

Electrical engineers have recently been devoting a great deal of attention to the transmission of energy by small currents at high pressures; and it is clearly advantageous to increase the potential difference until the expense of insulating the apparatus neutralises the saving in copper. The question of insulation is, of course, the main difficulty, for as we increase the potential difference many substances, which are ordinarily considered insulators, have to be regarded as fairly good conductors. Numerous experiments were shown to illustrate this point, the current being obtained from a Hedgehog transformer, capable of developing about .25 h.p. at 100,000 volts, which had been lent for the occasion by Messrs. Swinburne and Co.

The question of sparking distance in air does not seem to be of any great practical importance, but as it has recently been referred to, the following figures, obtained at Messrs. Swinburne's works, may be of interest:

Sparking Distances Between Needle Points.

P.D. in volts.	Sparking distance in inches
3,000	0·11
14,900	0·5
24,000	1·0
39,000	1·6
50,000	2·2
62,000	2·8
74,000	3·5
92,000	4·5
97,000	5·0

Sparking Distances Between Plates 2¼in. Diameter.

P.D. in volts.	Sparking distance in inches
13,000	0·16
20,000	0·40
44,000	1·0
70,000	2·0
90,000	3·0
105,000	4·0

The above results were obtained on a cold, dry day, but can only be regarded as approximate, as the distance was found to vary a good deal with atmospheric and other conditions, so that concordant results could not always be obtained on different days. By striking an arc between electrodes of tin wire, which gradually melted, a flame of considerable length was exhibited, and it was pointed out that the length to which an arc could be drawn depended very largely on the current strength available.

It was next shown that for overhead work at very high pressures even oil insulators of the best design are quite useless. Wires from the transformer were connected to the stalk and groove of an insulator which had been dried and filled with clean rosin oil; brush discharges immediately occurred over the surface of the porcelain, and when a P.D. of 60,000 volts was reached a spark jumped from the wire to the stalk. Two wires were placed near the ends of a piece of slate about a yard long, and sparks passed freely from the wires to the slate, and a sort of arc lamp was arranged with slate pencils for electrodes. A similar conducting power was shown to be possessed by vulcanised fibre and asbestos millboard. The discharge does not break down or perforate these substances; they behave exactly like conductors. A curious effect was shown with a long piece of slightly damp wood, numerous small arcs being formed, which finally ignited the wood.

The experiment with the oil insulator, and other experiments shown, point to the fact that surfaces of insulating materials, unless absolutely clean and dry, have considerable conducting power. A discharge may sometimes take place on the surface of a non-conductor across a distance much greater than the striking distance in air, and once a discharge has started an arc is formed. A cable insulated with a layer of rubber a foot thick might be useless for 50 or 100,000 volts, if it had even a small crack. This creeping discharge was also shown by the now familiar experiment in which a pair of discs are separated by a large sheet of glass. In one of the experiments shown the glass did not break, though the discharge passed through it, and it was found that if there ever had been a perforation the heat of the arc had fused the glass and entirely sealed up the hole.

The potential difference required to break down or perforate insulators is quite a different matter from the discharge over their surfaces. A number of samples of broken-down insulators were exhibited. They were materials which had been tried for use in condensers, and were in the form of thin sheets of mica, celluloid paper impregnated with various resins and waxes, etc., and were about six mils thick; they had been perforated with potential differences varying from 2,000 to 6,000 volts. A piece of cable insulated with a layer of vulcanised rubber of the best quality, rather over ½in. thick, was shown: it had withstood 50,000 volts for 25 minutes. In such cases the time element is of great importance, and the dielectric is usually found to become very hot before it breaks down. This fact indicates a very important difference between the effects of direct and alternating currents on insulators. Whenever, as in the case of a concentric cable, the two conductors are at all close together, we have a condenser which is being rapidly charged and discharged. Now in the case of most solid dielectrics there is a good deal of soaking in, and consequent loss of energy, which manifests itself as heat. This was made very evident in the case of a condenser which was tried at Messrs. Swinburne's works. This condenser was made of sheets of tinfoil insulated with paper soaked in paraffin wax in the usual way; its insulation, measured with a steady E.M.F. of 240 volts, was about six megohms, and

* Abstract of paper read before the Old Students' Association of the City and Guilds of London Institute, at the Central Institution, South Kensington, on March 11.

the active surface of plates was 5,000 square inches. When it was connected across a 2,000-volt circuit, it was found to absorb more than a horse-power, so that a considerable rise of temperature was not surprising. But it was also noticed that its capacity rapidly diminished, and finally disappeared, which was, on investigation, found to be owing to the fact that the foil had melted and so become disconnected from the circuit. Another condenser, made with glass plates $\frac{1}{16}$in. thick, broke down with 2,000 volts after about five minutes, apparently owing to internal cracks caused by the heat evolved. In the case of the sample of rubber-covered wire above referred to, the compound in which the braiding had been soaked, melted in five minutes, and the rubber became quite softened by the heat in about 15 minutes.

This heating effect is much less in the case of most fluid insulators, but seems to be more important in oils having a high specific induction capacity.
